This, though, is only the first object of *horror temporis*. Despite the monstrous nature of these creatures, Lovecraft's narrator evinces considerable sympathy for the Great Race and their project to gather knowledge, and secure their future survival, by this process of mind exchange. The organisation of their social system by 'a sort of fascistic socialism' dominated by a clerisy implies a kind of cosmic Keynesian planner-State of the kind Lovecraft himself obviously approved. The crisis that State has to manage is the threat of the elder beings – the second object of horror. These 'half polypous, utterly alien entities' are only partly material (here we see the purification of the object) and dominated the earth six hundred million years ago. The Great Race would subdue these creatures beneath the cities they had built and which were then occupied by the Great Race. The old mole of alien class struggle had literally gone underground only to sporadically erupt in revolutions 'shocking beyond all description'. The final flight of the Great Race to new bodies would be caused by the 'final successful irruption of the elder beings'.[5]

This little allegory of 1917 and the New Deal requires little deciphering, especially after China Miéville's reading of *At the Mountains of Madness* (1931).[6] The layering of these two objects of horror can be found in Peaslee's exploration of the ancient city of the Great Race in the Australian desert, as he searches for definitive proof of his abduction. The city itself forms an abyss, parallel to the horror of the vortex, with its 'vast chain of aeon-dead black gulfs'. Within the abyssal city, however, there is a further abyss. This is one of the prisons of the 'elder things': a 'downward aperture' open and 'yawning unguarded down to abysses past imagination'. Returning back past the open trap door Peaslee stumbles and hears the resultant noise answered by 'a shrill, whistling sound, like nothing else on earth, and beyond any adequate verbal description' – the sound of the elder beings. These 'tides of abomination surging up through the cleft itself'[7] fill-out the abyss or vortex with a material presence. Unlike *At the Mountains of Madness* we are not greeted with the appearance of these creatures; instead they remain signalled only by sound.

---

[5] H. P. Lovecraft 'The Shadow Out of Time', 502, 504, 505, 506.

Therefore this filling-out of the abyss is withdrawn and we are faced with a further layer of the shadow. The alien whistling of the creatures calls up another fear, the fear of being 'engulfed in a pandemoniac vortex of loathsome sound and utter, materially tangible blackness'.[8] The 'materiality' here is the subtractive or purified materiality of the vortex of seething time – the seething blackness of chaos. Recall 'The Music of Erich Zann' (1921),[9] in which the mad music of Zann is played to ward off something worse: 'the blackness of space illimitable; unimagined space alive with motion and music, and having no semblance of anything on earth.'[10] The narrative had earlier made clear how even the horror of the elder beings is finite; the Great Race knows that these creatures 'were slowly weakening with the aeons. Indeed, it was known that they would be quite dead in the time of the post-human beetle race which the fleeing minds would tenant'.[11] No consciousness, alien or human, subtends the seething vortex of time.

---

[8] Ibid., 541.

[9] H. P. Lovecraft 'The Music of Erich Zann' in *Omnibus 3*, 335-345.

Sound is then only the signal for the definitive rupture of the *musica universalis* – and the revelation of the real qua chaos – compact but full of holes. But this effect is withdrawn. The final 'shattering' revelation of Lovecraft's narrative is the – by now for the reader, entirely predictable – recovery by the narrator of a text from the depths of the alien city written in his own hand. This forms the definitive proof that 'there lies upon this world of man a shocking and incredible shadow out of time'. In this revelation we witness the retraction of the horror back towards the constraints of the object. Lovecraft himself remained dissatisfied with the story and refused to type it up. If every critical reading is a kind of rewriting, and often, as in this case, something of the expression of the text we desired rather than the text we have, then what I desire is that 'terrible thing': a fiction of the 'seething vortex of time'.

> I, Nathaniel Peaslee, have found that last proof of my otherness written in my own hand. But then this textual proof serves to keep me guarded as one of the chosen of the Great Race. I is another, another subject. We might all be doomed but I,

Nathaniel Peaslee, have had the honour of being chosen as a great mind who will be recorded.

Something, however, whispers in poor Nathaniel's ear: What about the shadow out of time? You presume that the shadow comes from outside. You suggest, implicitly, some stable and material outside that forms the flipside of existent reality. I come with the good bad news, the shadow out of time does not exist outside time, it is time. Time itself is the shadowy vortex of a 'matter' that forms nothing and has no need of you, anyone or anything else. Good night Nathaniel and good luck.

Being and Slime: The Mathematics of Protoplasm in Lorenz Oken's 'Physio-Philosophy'

Iain Hamilton Grant

> *It is a daring act of reason to set humanity free and to abstract the shock of the objective world; yet the venture cannot miscarry, since man becomes greater to the degree he knows himself and his strength.*
>
> Schelling[1]

> *A philosophy or ethics without a philosophy of nature is a non-thing, a bare contradiction, like a flower without a stem.*
>
> Oken[2]

1. INTRODUCTION: THE NON-THING OR, ON THE FORMS OCCURRING IN CONTEMPORARY PHILOSOPHY

The fate of post-Kantian philosophy depends on whether the 'shock of the objective world' can be overcome by self-knowledge, on the actuality of the 'shock of the actual'.[3] A seismic chain runs through transcendentalism's subjugation of earthquakes to epistemology, a vulcanism poignantly articulated in the objections of the cosmologist Johann Heinrich Lambert to Kant's relegation of time to an a priori form of inner intuition: '*If changes are real, then time is real* […] *If time is unreal, then no change can be real*'.[4] This is the shock of physics shattering the insularity of transcendental subjectivity, demonstrating the stakes of the modal investigation of epistemogenesis with which the transcendental philosophy attempted to replace ontology.

Schelling's account of transcendentalism as a 'daring act of reason' clearly articulates the substitution of ethics for ontology that lies at its core. The accuracy of this diagnosis is certainly revealed in transcendental philosophy's restriction of reality to the scope of possible intuition,

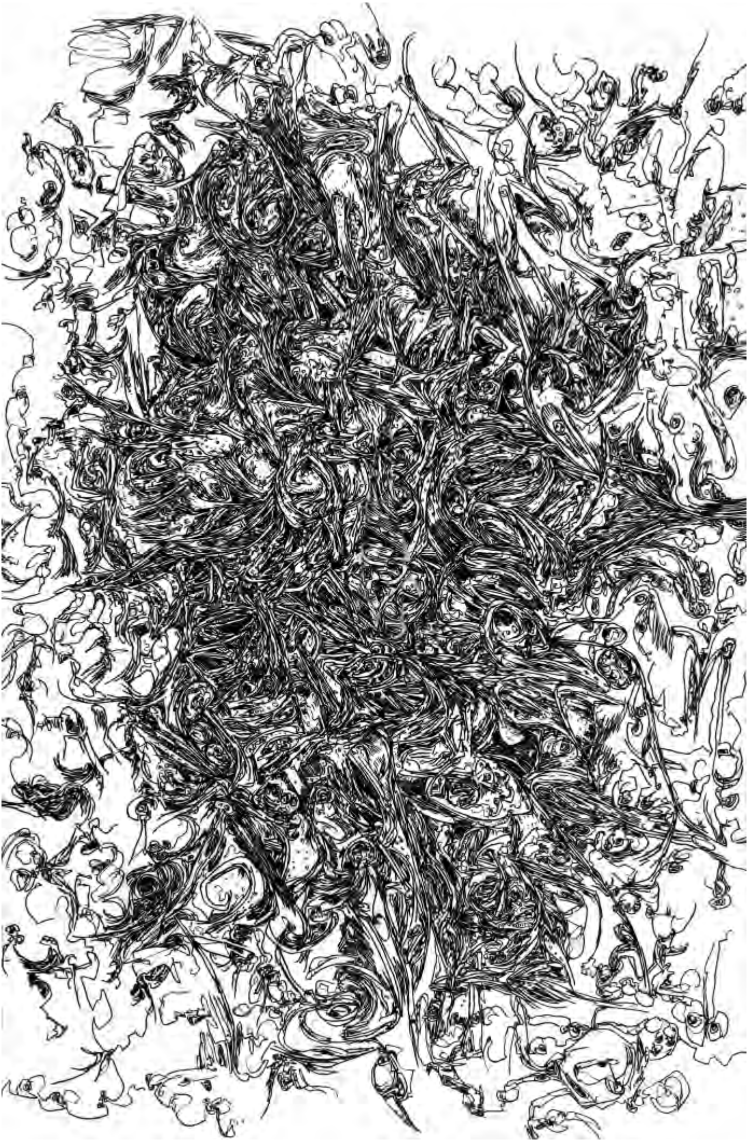
3. Novalis, *Heinrich von Ofterdingen*, as cited by Hegel in the *Rezensionen aus den Jahrbüchern für wissenschaftliche Kritik* in *Georg Wilhelm Friedrich Hegel. Werke* ed. Eva Moldenhauer und Karl Markus Michel (Frankfurt am Main: Suhrkamp, 1979), vol.11: 215. Interestingly, Hegel is here discussing the relation between actuality and freedom.

4. Lambert, Letter to Kant of October 13th 1770 in *Kants gesammelte Schriften* (Berlin: Königliche Preussische Akademie der Wissenschaften, 1902ff), cited *Ak*. Here *Ak*.X: 107 (italics in original). Lambert is responding to § 14 of *On the Form and Principles of the Sensible and Intelligible World*, where Kant argued that 'although time, posited in itself and absolutely, would be an imaginary being […], it is a condition, extending to infinity, of intuitive representation for all possible objects of the senses' (*Ak*.II: 401; 1992a: 395). Kant echoes Lambert's question and his response in the first *Critique*: 'Time is certainly something real, namely, the real form of inner intuition' (A36-6/ B53-4).

but its terms are more overtly displayed in the unstable dualism of teleology and mechanism in the third *Critique*. The dualism is unstable, because despite appearances, it is not *only* a dispute about natural causality (although this is certainly part of it), but outlines the procedure whereby physical grounds are reduced to the inscrutable abjecta of reason's ultimately moral actualisation. This procedure consists in (a) maintaining the phenomenal indifference of moral and natural purposes in keeping with the constraints placed by the first *Critique* on theoretical reason; while (b) extending the authority of practical over theoretical reason, in keeping with the second *Critique*; and *thereby* (c) rejecting ontology for an ethicised phenomenology. It should be noted, moreover, that the logical form of this procedure is self-reinforcing: (a) + (b) = (c) = (a) + (b). We shall call it the ethical process.

The claim of this paper is that this ethical process is as untenable as it is ubiquitous. It is point (c) that makes it recognisably ubiquitous, although usually (not always) without the string of reasons (a) and (b) that establish it. It is untenable because reason must now affirm ethical grounding as the absence of grounds, or *the absence of grounds as ethical grounding*. The ethical process is the principal element of the philosophy of what Oken, above, calls the 'bare contradiction, the non-thing'.

In the equation of 'bare contradiction' and 'non-thing', it is clear that Oken considers logical forms to entail ontological consequences: that a *bare* contradiction *is* a non-thing. This is in complete contradiction to the verdict of Hegel's *Philosophy of Nature*, where he dismisses Oken as practising a 'mere formalism' comprising nothing but 'assertions' common to 'the philosophy of nature of his



time'.[5] In contrast, what the geological *Naturphilosoph* Henrik Steffens called Oken's 'hard, insurmountable realism'[6] consists, in part, in a realism with regard to *grounds*. The core philosophical problem to which Oken's *Naturphilosophie* is addressed is consequently to determine 'how something derived its existence from nothing'.[7] As will become apparent, the 'nothing' from which 'somethings' always derive their existence is the mathematical nothing, the *zero*. Thus, Oken's 'generative history of the world'[8] consists entirely in demonstrating the *repeated* ontological consequences of what he calls, emphasising this generative operation, the *mathes*-is issuing from Zero. Thus, the formal reason of an existent is = the real ground of existence = 0. The question is whether the zero is always the same, i.e. whether 0 is always = 0, or whether, for instance, in the domain of biology, the 0 is *slimy*.

The story is often told that the immediate post-Kantian reaction consists in the 'organicist turn', with Goethe, Schelling and the *Naturphilosophen* cited as evidence. While it is certainly true that the post-Kantian philosophers and naturalists attempted to resolve Kant's dualism by way of organic or self-organizing causality, this story remains philosophically inadequate. In brief, the reasons for the insufficiency of this story are (i) that it segregates philosophy from nature, making the former merely the corollary of the latter; and (ii) that by making the naturalisation of teleology versus cognitively insuperable intentionality (the problem of 'access') into the only significant problem to which the Idealists contribute, it (iii) leaves the problem of the forms of realism pursued in the long aftermath of Kantianism, entirely unaddressed. This essay will therefore take Oken's Mathesis as a particular case study in the pursuit of a post-Kantian realism reducible neither to dogmatism nor to the ethical process, a pursuit that remains as insistent today as it did two hundred years ago.

[5] Hegel, *Philosophy of Nature,* trans A.V. Miller (Oxford: Oxford University Press, 1970) §346*, Zusatz*. There are moments in the *Elements*, notably its first section, that seem to ratify Hegel's assessment: 'Philosophy, as the science which embraces the principles of the universe or world, is only a logical, which may perhaps conduct us to the real, conception.' Hegel ignores countervailing propositions: 'what holds good of mathematical principles must also hold good of the principles of nature' (*Elements* 67).

2. Physio-Philosophy as the System of the Generation of the World

The *Elements of Physio-Philosophy* (*Lehrbuch der Naturphilosophie*) is a summative work that synthesises Oken's previous researches. Since his Preface to the *Lehrbuch* provides a retrospective of this works, and since, like most of the *Naturphilosophen*, Oken remains as scorned as he is ignored, we will introduce the main points of Oken's system through his own bibliographical commentary.

Oken's first work, the *Outline of Nature Philosophy, Theory of the Senses and the Animal Classification based Thereupon* (1802), sets out from the thesis that 'the animal classes are virtually nothing else than a representation of the sense-organs', a position by which, he states, he 'still abides' in the *Elements* (xi). This is notable both in its attempt to infer a system from physiological particulars, a realism that will survive, just as it is inverted, in the *Elements*; and in the structural role it allots to the theory of recapitulation, further developed and exemplified in this gloss of the theory as propounded in *On the Significance of the Cranial Bone* (1807):

> […] the head is nothing other than a vertebral column […] [just as] the maxillae are nothing else but repetitions of arms and feet, the teeth being their nails […][9]

This 'vertebral theory of the skull', over the discovery of which Oken disputed with Goethe,[10] not only 'supposed a community between the human skull and that of the lower vertebrates', but extended beyond the organic into the mineral, geological and cosmogenic domains, carrying the 'law of serial repetition […] to ludicrous lengths' in Oken, according to some.[11] While such a law must lose in determinacy what it gains in extent, the principle behind it is simple: that no product of nature arises in isolation from all other products, each being dependent on others, 'tak[ing] its starting-point from below', as Oken notes.[12] How far below, however, must research plunge in order to locate the basal, serially repeated element? Writing retrospectively in 1846, this is what the neurophysiologist Jacob Henlé called the 'genetic method', which had as its goal 'to identify the simple type of a given structure and to trace its progressive elaboration'.[13] Where the genetic researcher is in possession of the fully elaborated organ, the task is simplified; insofar as the basal element of any living organisation is to be encountered within the domain of the biotic, the task becomes simpler still: to find the basal type of all life.

---

[9] *Elements,* xii.

[10] As notably discussed by Hegel in his *Philosophy of Nature*, §354 *Zusatz*: 'Oken, to whom Goethe had communicated the treatise [*On Morphology* 1785], paraded its ideas as his own in a programme he wrote on the subject, and so gained the credit for them.'

[12] *Elements,* zxiii.

[13] Cited in Clark and Jacyna (1987), 21, 43.

However, if in principle there are no independent products in nature, then the prospect of an end to the genetic typing of any natural product is not to be found in the part, but rather in the whole. Oken's next work will accordingly transform the search for nature's basal elements into the search for 'the nature of nature',[14] or metaphysics.

Combining the results of the *Outline* and *Significance*, Oken's *On the Universe as a Continuation of the Sensory System* (1808) argued 'that the Organism is nothing other than a combination of all the Universe's activities within a single individual body' and that 'World and Organism are one in kind, and do not stand merely in harmony with each other'.[15] The last clause here indicates an important thesis regarding the theory of recapitulation, which does not assert that there merely exists a contingent 'harmony' or phenomenal similarity between parallel series (e.g. world-generation and speciation) that remain of fundamentally different natural orders, but rather that all of nature is involved in the generation of any part of it. Moreover, as evinced by the work's title, Oken is no longer concerned, as he was the *Outline*, to derive merely formal devices from physiological givens, but rather to assert that this structure is *really instantiated* in the universe as such. Accordingly, Oken extended his systematising attention to the elements of physics in *First Ideas towards a Theory of Light, Darkness, Colour and Heat* (1808), where each of these phenomena are derived from tensions, antagonisms and motions in the aether, constituting a 'primitive field theory',[16] and in the *Natural System of Ores* (1809), where mineral particulars are considered for the first time.

---

[14] Novalis, *Werke 2: Die Christenheit oder Europa und andere philosophische Schriften*, ed. Rolf Toman (Köln: Könemann, 1996), 440.

[15] *Elements,* xii.

While the resultant dynamics fulfilled the post-Kantian brief for physics established especially by Franz von Baader's *Ideas On Rigidity and Fluidity* (1792), Apolph Karl August von Eschenmayer's *Propositions from the Metaphysics of Nature applied to Chemical and Medical Objects* and *Attempt to Derive the Laws of Magnetism A Priori from the Propositions of the Metaphysics of Nature* (both 1797), Oken had also to integrate the phenomena of life into this universal physics. While it is only in the *Elements* that this is achieved, Oken's contribution towards it – the theory of 'primal slime' or protoplasm – was first advanced in *On Generation* (1805), which argued

> […] that all organic beings originate from […] the infusorial mass, or the protoplasm [*Urschleim*] from whence all larger organisms fashion themselves or are evolved. Their production is therefore nothing else than a regular agglomeration of […] mucus vesicles or points [*Schleimpunkte*], which first form themselves by their union or combination into particular species.[17]

Since naturephilosophy is to be 'the generative history of the world',[18] rather than that of biological individuals alone, the *Elements* undertakes to synthesise the sensory, cosmogonic, geological, embryological and philosophical systems into a single, self-recapitulating series. The question arises as to how primary the ‘primal slime’ is. Written prior to the cosmogonic synthesis of *Of the Universe*, Oken’s programme in *On Generation* has not yet undertaken the transition to from the physics to the metaphysics of nature. Thus, as briefly digested as the *Elements* is vast (numbering 3652 propositions), Oken describes its project as finally

---

[17] *Elements,* xi-xii.

[18] Ibid., 11.

> [...] bring[ing] these different doctrines into mutual connexion, and to show, forsooth, that the Mineral, Vegetable and Animal classes are not to be arbitrarily arranged in accordance with single or isolated characters, but to be based upon the cardinal organs or anatomical systems, from which a firmly established number of classes must of necessity result; moreover, that each of these classes commences or takes its starting-point from below, and consequently that all of them pass parallel to each other.[19]

Yet even here Oken holds out a physicalist solution to the genetic problem, noting that a *parallelism* between the classes make it possible ‘to prove that they by no means form a single ascending series’.[20] Although the primacy of primal slime may thus yet be safeguarded, how the *Elements*’ project is to be achieved is set out in the opening sections of the work, which introduce the naturephilosophical terms of reference. Amongst the most important of these is the actual and logical priority of natural ground:

> Naturephilosophy is the first, philosophy of mind, the second: the former, therefore, is the ground and foundation of the latter,

---

[19] *Elements*, xiii.

[20] Ibid.

> for nature is antecedent to the human mind. […] Without naturephilosophy, therefore, there is no philosophy of mind, any more than a flower is present without a stem, or an edifice without a foundation.[21]

Moreover, since naturephilosophy 'has to show how, and in accordance indeed with what laws, the material took its origin', it follows that history forms a single temporal series from the development of matter to particular natures to mind. The formal reason = real ground of existence consists in the various solutions to the problem of 'how something derived its existence from nothing'.[22]

The other element, then, is Zero, the nothing, and it is introduced in the *Elements* for the first time as *paralleling* the *Urschleim* in biology. In what sense, however, 'parallel'? Are the biological and the mathematical parallel and thus independent, or does everything depend on 'what is below it'? The problem of the relative and mobile primacies attaching to the various basal types running throughout Oken's system is that Zero is the equilibrium point in Oken's polar philosophy of nature, and is so dominant that it led Steffens to describe Oken's 'insurmountable realism' as complemented only by an 'ideal element' that is 'entirely negative', a view Knittermeyer endorses.[23] The basal Zero – 'Oken's most pervasive principle' – states that 'all development proceeds along the same path by adding elements to an original nothingness', a law that 'holds for human ontogeny, the historical sequence of species, the evolution of the earth itself'.[24] This account certainly follows from the irreversible priority Oken attaches to Nature over Mind; but the problem remains: *either* the Zero is the merely *formal* element Hegel accused Oken's naturephilosophy as consisting in, in which case 'The universe' is *not* 'the reality of mathematics';[25] *or* 'existence derives from nothing' and Slime is *not primal.* The Okenian solution to the genetic problem therefore consists in a struggle between Nothing and Slime.

---

[21] *Elements* 15-16, t.m.

[22] Ibid., 10.

[23] *Schelling und die romantische Schule* (op.cit.), 192.

3. ZERO OR SLIME? THE ELEMENTS OF THE *ELEMENTS* AND THE GROUNDEDNESS OF THE GROUND

The *Elements* outlines its system in sections 18-21 of its 'Introduction'. The 'generative history of the world' divides into three parts:

1. Mathesis (of the whole),
from which stem (a) Hylogeny and (b) Theogony, or the
generative philosophy of matter and mind;

2. Ontology (of the singular),
which follows the generation of nature from Mathesis, and from
which stem (a) Cosmogony and (b) Stoichogeny; and

3. Biology (of the whole in the singular),
which recapitulates the generation of Hylogeny, Theogony and
Ontology in embryogenesis.

Mathes*is* – the *actions* of mathematics, 'the only true, the primary, the universal science'[26] – subdivides in turn into the theories of material totalities or Hylogeny, a 'rather primitive field-theory'[27] comprising aether, light and heat; and of immaterial totalities or Pneumatogeny, a Theogony comprising God and Nothing. Ontology divides into Cosmogony, or the emergence of the cosmic bodies, and Stoichogeny, or how the heavenly bodies 'divide themselves further […] into the elements'. Biology, concerned with 'the whole in singulars [which] is the living or *Organic* […] divides into *Organogeny, Phytosophy* and *Zoosophy*'.[28]

---

[24] Stephen Jay Gould, *Ontogeny and Phylogeny* (Cambridge MA: Bellknap Harvard, 1977), 44, 40.

[25] *Elements* 2.

Two things concerning Oken's conception of Biology are immediately apparent. The first is that it is no longer predicated, as was Oken's procedure in the *Outline* (1802), on a particular kind of being whose contours are given *in* nature, but rather on a particular stage in the development of structural complexity *involving* God, Nothing and Matter, or mathematics, singulars and substance; that is, the whole of nature. Since the whole is the self-division of God, Nothing and Matter, and the singular is the elemental, hylogenetic singular attained *and actualised* through these divisions; and since further it is articulated primarily by mathematics, then the true object of Biology is the mathematics of these self-divisions as actualised in living somethings. This is the fork in Biological science that leads to the theory of the Primal Slime (*Urschleim*) and its manifestation in Slime Points (*Schleimpunkte*). The theory of slime which forms the oozing ground of Oken's 'physio-philosophy' is ultimately therefore a 'mathematics endowed with substance',[29] or the product of the mathetic-ontogenetic process; the biogenetic process then 'takes its starting point' from the 'infusorial mass' or 'primal slime' *below*, which it divides into the innumerable 'mucus vesicles [*Schleimpunkte*]' that are the 'primal constituent parts of [this] organic mass'. The production of complex singulars (individuals) consists therefore in the 'agglomeration of infusoria' up to the level of species.[30] Biology is therefore the science of the production of individuals that has as its basis the science of the production of wholes.

---

[26] Ibid., 24-5

[27] Mullen (1977) *Loc.cit.*

[28] *Elements,* 21.

Secondly, if the system that supports this account of the organic is a *true* system, that is, if the philosophy of nature is not merely a reflection upon nature, but rather 'the generative *history* of the world',[31] a world that articulates 'mathematical propositions' as much as it generates 'natural things',[32] then it follows that Biology is no isolated science of abstracted particulars, but rather concerns the developmental singularities by which the mathematicising cosmos is actualised. Hence Oken's insistence that

> Natural History is not a closed department of human knowledge, but presupposes numerous other sciences, such as Anatomy, Physiology, Chemistry and Physics, with even Medicine, Geography and History.[33]

Biology becomes the science it must when and only when the totality of the sciences – of wholes, singulars, and singulars-in-wholes – recovers the *entirety* of science as such. This means that Biology recapitulates Mathesis, just as Oken's categories suggest: of the Whole, and of the Whole in the Singular. The *one* science of the whole is mathematics, the language of ontogenesis. From this second perspective, Oken derives what many, including Hegel, deride as the 'empty formalism' of his system, a formalism articulated around an irreducibly ontogenetic element: the 'oscillating Zero', or God: 'God is = + 0 –'.[34] The problem of the relation between the multiplicity of sciences and the 'universal science' arises starkly: *either* there is one universal science to which all others are reducible, *or* Mathesis, the theory of the whole, has no claim to universality, and does not therefore articulate ontogeny. In short: *what is the relation between the Primal Slime and the Zero*? Oken's proposed solution is: mathematics is the universal science that generates, interconnects, and necessitates all the others. The 'wavering Zero' is the generative core of being and slime.

---

[29] Ibid., 26.

[30] Ibid.,xii.

[31] Ibid., 11.

[32] Ibid., 30.

[33] Ibid., xiv.

The problem of priority is a problem for a metaphysically realist natural history precisely because the theory of recapitulation, considered causally, abolishes linear time. Whenever there arise claims to priority (the primal Zero or the Primal Slime), Oken appears to equivocate. Having noted therefore the priority of the philosophy of nature over that of mind in section 15; along with the ontogenetic dependency of the latter on the former ('nature is antecedent to mind') in section 16; section 17 concludes *not* with this serial genetic dependency, but with a 'parallelism' between the two. One section later, however, the parallelism is extended to the relative priorities of the one over the other. Thus:

---

[34] *Elements,* 99. Knittermeyer puts Oken's case economically and concisely: 'God is the father, the generator, but himself ungenerated, transformed into the plus and the minus and yet always remains himself as the existent nothing [*das wesende Nichts*]. God is the son who goes forth from the father into finitude, and he is the mind that takes finitude back, in turn, to the origin and reproduces the "mental bond" with the generating origin. As the first, this divine acting is the 'primary rest [*Urruhe*]', the "wavering and resting point in the universe", the "never appearing and yet ubiquitously present". As the second he is eternal ponentiation and hence, corresponding to the number series 1 + 2 + … + *n*, the creator of the temporal series. As the third, however, God is he who takes back the finite [being] released into the restless time effecting motion and life, into the whole and binds it into him in all-filling space. The formless oscillation of life here receives form and integument. The divine brings itself closer to appearing and therefore materiality.' (Hinrich Knittermeyer, *Schelling und die romantische Schule*. München: Ernst Reinhardt, 1928, 189).

> It will be shown in the sequel that the mental is antecedent to nature. Naturephilosophy must, therefore, commence from the mind.[35]

Which, then, does come first – Zero or Slime? Around what axis is the topology of nature and mind spinning? Does mathematics remain the 'primary science', or is a mathematical realism usurped by a realism concerning natural history? The relation of system and history remains at the core of the metaphysics of natural history; especially as this project was renewed in Prigogine and Stengers new 'physiophilosophical' alliance.[36] What is seldom noted is that this entails a *natural history of metaphysics* that extends beyond the steady accumulation of form that characterises Hegelian history of philosophy. The natural history of metaphysics is a *physics* of metaphysics, a science of the grounds of metaphysics in nature, or a physics of ideation as such. Although sounding more redolent of hard-nosed contemporary eliminativists than of post-Kantian idealists, this recognition was core to *Naturphilosophen* such as

Schelling, who characterised philosophy as 'the natural history of mind'[37] and Troxler, who defines metaphysics as the physics (*Naturlehre*) of human knowledge.[38] If nature is necessary to generate mind, as sections 15 and 16 note, then mind is necessary to the abstract recapitulation of natural production in reflection, or to the recapitulation of the mathetic whole in the biological singular. Yet Oken's system extends beyond reflection on natural production, since ontogenesis depends on Mathesis. The Platonic kinship is unmistakable:[39] mathematics, or the Idea, are not simply nominal or formal processes, but rather ontogenetic. Just as the *Phaedo* argues[40] that it is *because* of the form of Beauty that beautiful things exist, so Oken argues that it is *because* of Mathesis that things exist, or because of Nothing (= 0) that there are beings. That Oken inverts the causal or physical dependency of mind on nature does indeed stem from his characterisation of Mathesis as hylogeny *and theogony* , which gives *direction* to the system, towards the production of animals capable of Mathesis and therefore, famously, of man:

> Man is the summit, the crown of nature's development, and must comprehend everything that has preceded him [while] man is a complex of all that surrounds him, namely, of element, mineral, plant and animal.[41]

[40] *Phaedo,* 100d.

[41] *Elements,* 12, 98.

At the very point where *thinking slime* affords nature linearity, however, at the crown of its development from elements to animals, directionality reverses. Mathesis as theogony is concerned with the immaterial whole; yet what is the 'immaterial'? Merely 'that which is nothing in relation to the material',[42] just as 'God is = + 0 –'[43] or 'the eternal is the nothing of nature'.[44] The 'immaterial' is the zero of material, its generative ground, just as God is that of nature, since nothing iterated is the becoming of something. Thus the sense in which 'something derives its existence from nothing'[45] now becomes 'very clear'. Just as

> numbers have not issued forth from zero as if they had previously resided therein, but the zero has emerged out of itself […], and then it was a finite zero, a number[46]

so something emerges not 'out of' but rather from the *acts of* the nothing's self-extensions: 'Zero is […] the primary act [and] numbers are [its] repetitions'.[47] Thus another primary whose 'positing and negating are called realisation [which] is a process of extension taking place in the Idea'.[48] And this positing *and negating* takes place, equally, in the 'highest, most exalted art […] of war',[49] reducing everything to

[49] Ibid., 3652.

nothing after the Napoleonic model. The nothing initiates a ceaseless *imitatio nihil* amidst the extended multiplicities formed of the infinite repetition of the primary act, while existence resists the sink at its core.

At first sight far from satisfactory, all this wavering Nothing leaves an ontological queasiness in place of any principle of sufficient reason. It pervades Oken's system, with its martial apex. For what kind of biologist does war supercede life as the system's goal? That the complexifications of Primal Slime here cede to the destruction of war demonstrates that the cosmos worships the Nothing-God. The culmination of Biology is the destruction of individuals, which is held in check so long as there remains *something*. Kant tells us, reassuringly enough, that reality can never sink to zero; but Oken's *mehylotheogony* supplants all Being with increase and decrease, *each limitless*. The fragile hold of beings is secured by Slime alone – all that ontology can hope for is Slime potentiated and negated into and out of all things. The question thus arises is this: is the *Urschleim* – or, ontically speaking, the *Schleimpunkte* – negable, reducible, as well as 'potentiable'? The prospect of the *contingency of all beings* issues directly from this as it were gravitational distortion of the local spacetime of their generation.

The question would hold no terror were the passage from mathetic metheology to ontology secured, e.g. by a causal or a linear-progressive process; but it is not. The whole is not left behind by history, by the accumulation of causes from whence emerges time; rather, it *returns* in Biology. Oken's Biology is *not* therefore testimony to the final discovery of a 'Newton of the blade of grass', of an organicism to save us from the ravages of nature, but only the repetition of the None-All in every generated particular.

All directionality, whether in ideation or cosmogeny, in embryogenesis, hylogeny, temporalisation or primary Mathesis, is withdrawn in favour of the *polar* model that determines the 'primitive field theory' Oken constructs around the tensions, antitheses and motions of the aether in the *First Ideas for a Theory of Light*, and which inherits and extends the galvanic process Ritter discovered to 'constantly accompany the animal kingdom' into the mineral, chemical and mathetic domains along the lines suggested by the magnetic schema, in which the zero is not primitive, but first and last in, and the principle of, all the extensions of its force.[50] Oken's mutiplicity of primaries – act, slime, rest, etc. – are primary relative *both* to the lower nothing from which, at ontogenetic root, they issue, and to the 'higher zeros' that counteract them which they in turn give rise: rest, war, act.

The polar metaphysics of nature, therefore, collapses the axis of higher and lower, antecendence and succession, into a field theory of polar dependency: 'The world is God rotating' or 'a rotating globe of matter'.[51] Natural history is always therefore *relative* to the mathetic zero from which its objects issue, and the frame of reference is always generated *after* the field that is its object. The ultimate significance of sections 15, 16 and 18 of the *Elements* is therefore that the priority of nature with respect to mind generates a nothing in nature from which naturephilosophy begins. Ironically, Oken's post-Kantian solutions make Lambert's physico-critical intervention redundant by *realising the full consequences of self-effecting processes:* the elimination of history in nature: 'Time is the infinite succession of numbers or the mathematical nothings'.[52] We turn now to Oken's solutions to his polar take on the genetic problem.

---

[50] The schema owes its most definitive account to Karl August Eschenmayer's *Attempt to Deduce the Laws of Magnetic Phenomena a priori from the Propositions of Metaphysics* (1797), and to Schelling's reworking of it in his *Exposition of my System of Philosophy* (1801). For Eschenmayer, see Jörg Jantzen, 'Adolph Karl August von Eschenmayer', in Bach and Breidbach, eds., *op.cit.,* 153-79 and Gilles Châtelet, *Les enjeux du mobile. Mathématique, physique et philosophie* (Paris: Seuil, 1993), esp. 137-9. On Schelling's transformation of the magnetic schema in his so-called Identity philosophy, see Iain Hamilton Grant, *Philosophies of Nature after Schelling* (London: Continuum, 2006), 158-82, and 'The physics of the world soul', in Judith Norman and Alistair Welchman, eds. *The New Schelling* (London: Continuum, 2004), 128-50.

[51] *Elements* 142, 161.

4. OKENIAN SOLUTIONS, AND …

Oken's solution to the genetic problem is not what Henlé's 'student of the nervous system' might have hoped for. Rather than identifying the 'basal element' of neurogenetic recapitulation, Oken resolves individuation into the whole. Schematically:

(1) *Mathesis→ Ontogenesis → Biogenesis → the production of the whole in the singular → Mathesis potentiated.*

(2) The consequence of this is that the causal series that ties time to change is sacrificed for a codependency relation, a reciprocity, between the elements recapitulating the basic scheme of the whole in a singular. 'The law of causality is a law of polarity', not of time.[53] Time, Oken continues, is accordingly 'only repetition, and thus also a suppression of

---

[52] *Elements* 72.

[53] Ibid., 79.

[…] positions'.[54] Because the whole is expressed at the apexes of individuation (Ideation and War), Okenian ontogenesis produces irreducibly local maps, while 'pneumatogenesis' *has primally and then derivatively* multiplied them. Potentiation is potentiation of the whole in its individuation, as Schelling would later note of the involutive-evolutive process.[55]

(3) If, logically, mathematics is the expression of the whole in the individual; and if, theogonically, 'God = + 0 − is before and after all things', then modally, only the nothing is necessary. Here, then, we derive the central lesson of Oken's system of nature: the contingency of all beings, so the 'principle of sufficient reason' is satisfied by *nothing* potentiated. Precisely in consequence of this, mathematics or mehylogeny does not so much *supplant* nature as *generate* it: by taking on the project of the 'natural history of metaphysics', Oken's slimy Platonic naturephilosophy has mathetic functions accreting numbers and organs, indifferently: 'all development', as Gould notes of Oken's system, 'begins with a primal zero and progresses to complexity by the successive *addition* of organs in a determined sequence'.[56] The zero accretes by self-extension in the forms of mineral, chemical, plant and animal organs.[57]

[56] Gould, *op.cit.*, 40.

[57] *Elements,* 867.

(4) If, as we have seen, recapitulation becomes, by virtue of (2), above, if not *aionic* (although Oken occasionally makes precisely this point: 'Zero must be endlessly self-positing, for in every respect it is indefinite or unlimited, eternal'),[58] then certainly *achronic*. It forms the logic of Idea in the hylogenetic → biogenetic process, and as such is the repeated intercession of the eternal into time, or its negation.

(5) Even anthropogenesis, so often criticised as the 'anti-copernican' core of the post-Kantian 'restoration', accordingly suffers. No sooner is man declared the 'highest', insofar as it is through man that nature achieves Ideation and thus *reproduces Mathesis*, than war erupts because 'the Nothing is higher than the highest': 'the Zero, the highest'.[59] Oken therefore demonstrates that anthropogenesis culminates neither in the humanism of finitude nor in the ontolotheological eschatology, but rather ceaselessly repeats the *mathetic mehylotheogony* of the cosmogonic process:

> In the process of destruction, the finite being seeks to become the universe itself [because] man is a complex of all that surrounds him.[60]

---

[58] *Elements* 53.

[59] Ibid., 40.

[60] Ibid., 91, 98.

5. … POST-OKENIAN PROBLEMS.

> The continuance of Being is a continuous positing of the Eternal, or of nothing, a ceaseless process of becoming real in that which is not. There exists nothing but nothing, nothing but the Eternal, and all individual existence is only a fallacious existence. All individual things are monads, nothings, which have, however, become determined.[61]

We have noted that the Okenian number series are primary, and issue from a primary Zero, 'the one essence of all things, the 0, the highest identity'.[62] Disregarding for the moment the metaphysics of polar time, the Zero is, if not primitive, then ultimate, insofar as everything resolves into it. Oken invests considerable effort in the elaboration of zero.

Firstly, it is twofold: intensive or ideal, and extensive or real. Yet these two remain indifferent: 'the real and the ideal are no more different than ice and water; both […] are essentially one and the same'.[63] This is where the repeatedly claimed similarity of Oken's Zero and Schelling's reformulated law of Identity are apparent:[64] that identity is the

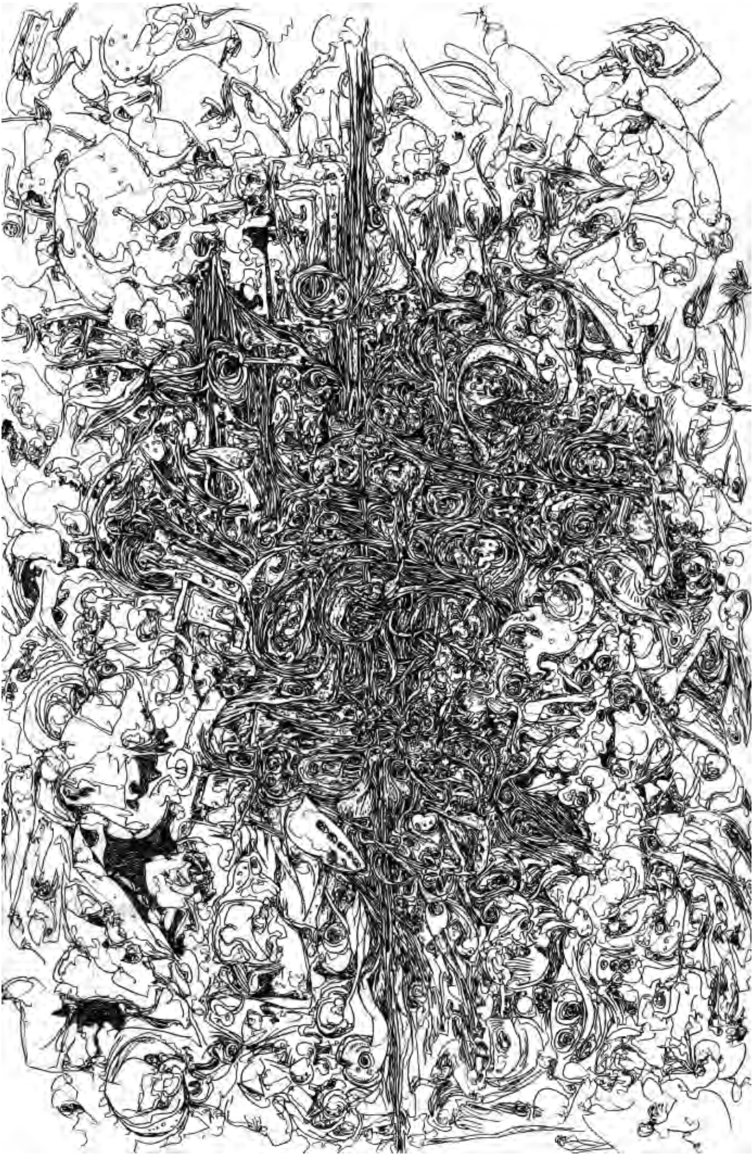
---

[61] Ibid., 58.

[62] Ibid., 40.

[63] Ibid., 36.

[64] This tendency starts with Oken's translator, Tulk: 'the present work stands alone in Germany, as being the most practical application upon a systematic scale of the principles advanced by Schelling, more especially in the Mathesis and Ontology' (*Elements* vi). More recently, Joseph L. Esposito, in *Schelling's Idealism and the Philosophy of Nature* (Lewisburg: Bucknell University Press, 1977, 143) repeats the point: 'Essentially Oken's system is the same as Schelling's, but with specific scientific disciplines superimposed on it, so that it became at once a picture of the World System and a proposal for how to study it. […] *Mathesis* is the condition of Schelling's Absolute Identity, wherein the first differentiation occurs'. See also Wolfgang Förster, 'Schelling als Theoretiker der Dialektik der Natur', in Hans Jörg Sandkühler, ed.,



ground of differentiation, and that no differentia, insofar as they are different, are identical.

Secondly, the susceptibility of Zero to 'infinitely numerous forms'[65] invites speculation as to the other forms it has in fact assumed: apart from Eschenmayer's magnetic schema, therefore, Kant's account of the eliminative actions of negative magnitudes, or the ontological problem of negative numbers, pinion around zeros, as does the 'minimax' of zero sum games, or the empty set from which Russell and Whitehead, on the one hand, and Badiou on the other, draw such diverse ontological conclusions. Finally, and perhaps decisively, the ungenerated and ungenerable, non-phenomenal attributes of the Platonic Idea make it into the zero of the physical world, a series of problems best explored in the *Parmenides*. The actual and potential permutability of zero into many formal schemas brings Oken's theorizing out of the domain of the 'number mysticism' of which he has been routinely accused[66] to demonstrate the ontological vitality of the problem of the relation of number, being and animal.[67] The question Badiou raises against Deleuze of the separability of mathematics and ontology, on the one hand, from nature on the other, is, as is topologically appropriate, twisted in Oken. *On the one hand*, Mathesis, ontology and biology form

distinct domains that are all, *on the other*, articulated by their respective and interrelated zeros. In other words, each series takes its starting point from its predecessor, so that Mathesis entails ontology entails biology. The problem of the independent dependence of series one on the other is in effect the problem solved by the generation of nature itself, insofar as it recapitulates these series in all its products. On Oken's evidence, then, number is inseparable from animal precisely because *animals are the numbers of nature*:[68] 'life', he writes, 'is a mathematical problem'.[69] Mathesis, ontology and biology are equally inseparable, therefore, because the series are not statically taxonomic, but actually genetic. *It is the genetic element in Oken that indicates a resolution to the contemporary problem*.

Thirdly, the Ideal and Real forms correspond to the Zero in a state of intensity and extensity in number series. 'The latter', writes Oken, 'is only expanded intensity, the former, extensity concentrated in the point'.[70] It is this latter differentiation that provides Oken with the means to formulate the issuing forth of something out of the nothing by way of the latter's repetition rather than its expulsion of a latent content.

The Zero thus provides a genuine solution to the problem of sufficient reason: *nothing* is the reason why there are beings, or is the ungrounding of primary ground from which grounds emerge. This thesis is rich in implications: firstly, since the determination of nothing occurs only in the process of extension and concentration, and since it is susceptible to 'infinitely numerous forms', it grounds *the contingency of all beings*, although it ought not to be omitted that it *grounds* this contingency of singulars. Secondly, if all things have one essence (= 0; *Elements* 40), then in what sense are all things really diverse? If merely *formally* (as Oken in fact argues), then ontology – the *actual* generation of singulars – cannot fulfill its function, and the All remains = 0; if *essentially,* then the Zero ceases to be the primitive = the highest in all things, and the All is not = 0. The problem this poses can thus be summatively stated: is the Zero capable of real generation? Since Oken answers that 'naturephilosophy is the generative history' or 'the science of the genesis of the world',[71] the formal and essential 'generations' of zero must be essentially indifferent while formally different. If, however, all difference is formal difference, and the Zero is always the generating (potentiable and negable) element, then it must either be concluded that formal difference is essentially indifferent or that formal differentiation is the generation of an additional mode *not given* in the alternatives. This, indeed, is Oken's solution: 'positing and negating the Eternal is called realisation'.[72]

---

[68] I owe this point to lengthy and unforgettable conversations with my colleague Sean Watson.

[69] *Elements,* 104.

[70] Ibid., 37.

What does the contingency of all beings therefore entail? That the formal differentiation and essential indifference of the generations of zeros never attain to fixity, whether of species, phyla or morphology. Indeed, this is guaranteed by the endlessly rotating axes of theogonic and hylogenic nature,[73] just as it is by Oken's 'singular to whole' transformation of the genetic problem. Accordingly, Oken's is a universal morphogenesis, which earned his work credit from D'Arcy Thompson[74] and E.S. Russell,[75] amongst others. Okenian ontology does not therefore so much chart whole entities, but rather *singulars*, both in the sense of *cosmogony*, or the generation of the *one* universe – 'there can be only *one* nature';[76] and of *stoichogeny*, or the generation of the elements and organs that accrete to the various *formally differentiated* singulars. Ceaselessly oscillating around the zeros from which they issue and the complexes they recapitulate, depending on the extensity of the zeros' generations, the emergent material forms are not so much limited geometries as they are limited *acts*.

---

[71] Ibid., 11, 66.

[72] Ibid., 40.

[73] cf. *Elements* 142, 161.

Taking these points together, it becomes evident that what the contingency conferred upon beings by Oken's principle of sufficient reason consists in is the consequence of the contingency of dynamics. On this account, biology is the science of the contingent dynamics of the primal slime, oscillating between the achievement of Ideation and mineral inertia. Indeed, the polar field thus generated by biology *involves* rocks as much as Ideas, as much as the biological singular involves the osseous and the nervous systems; all biological systems, however, are *evolved* from the slimy, protoplasmic mass whose contingencies are *involved* in them. To return to the problem of the separability of mathematics and nature, we must now pose it the other way round: *is a slime-free matheme possible*? Morphology, with its principle of sufficient reason, argues not.

---

[74] D'Arcy Thompson cites Oken twice by name in *On Growth and Form* [1917]. Ed & abridged by J.T. Bonner. (Cambridge: Cambridge University Press, 1966), and gives the following, Okenian account of morphology: 'Morphology is not only a study of material things and of the forms of material things, but has its dynamical aspect, under which we deal with the interpretation, in terms of force, of the operations of Energy', 14.

[75] E.S.Russell, in *Form and Function: a Contribution to the History of Animal Morphology* (London: John Murray, 1916), 90, thus describes Oken as'a careful student of embryology'. The most recent exponent of the positive view of Okenian morphology is Stephen J. Gould, *op. cit.*

[76] *Elements,* 166.

6. CONCLUSION: THE ROTATIONS OF THE BEFORE AND THE AFTER

With Schelling, we argued at the beginning of this essay that the *ethical process* is possible only if the 'shock of the objective world' can be abstracted away. One means of achieving this is by insisting on the separability of mathematics and nature, and by insisting on the 'impossibility' of a philosophy of nature, as does Badiou.[77] Another means of achieving this is by insisting on the insuperability of the nominal frameworks of self-conscious, finite reason. Since the latter is a subdivision of the former, however, there is no difference in kind, but only in degree, between these two means of abstracting the world.

Oken's insistence, by contrast, on the material world of nature as forming the generative basis not only of natural individuation, but also of the thought-series that can only arise on their basis in turn, suggests that one more entailment might flow from his principle of sufficient reason: the order of priority of nature and mind. With this order, the shock of conjoint time and change by which Lambert forced the progressive splintering of the system of transcendental philosophy, is reintroduced: if there is an order of priority, how can it be grounded given the ceaseless rotation of Matter and God? To resolve this merely formally, by arguing that

---

[77] Badiou, *loc.cit.*, 64.

Matter is the zero of God, just as God is the zero of Matter, is not to resolve the problem at all, but to avoid it, since Mathesis consists precisely in the formal differentiation of Matter and God – of hylogeny and theogony – from which ontogenesis flows. Further, we have already noted Oken's inversion of his initially stated order of priority: 'nature first, mind second'[78] becomes 'mind first, nature second'.[79] Since we must concede that Oken's dynamics admit of no transcendent or transcendental axes, therefore, the grounds of the before and the after must be established by other means.

Ultimately, as Oken repeatedly argues, the task of naturephilosophy is 'to show how [...] the Material took its origin; and therefore, how something derived its existence from nothing'.[80] By now we recognise this as Oken's trademark, polar procedure: matter and nothing are conjointly the first focus of the systematic task of generating nature *in thought*. Thought, in other words, *involves* matter and nothing, i.e., the whole (Mathesis). Indeed, philosophy and war are the latest of the zero's accretions, the former consisting always in 'the repetition of the origin of the world',[81] while the latter, through the 'process of destruction', seeks to reestablish the essential identity of everything[82] in the zero that must necessarily remain. Each involves the entire universe and its generation; the first as universal repetition, the second as universal equation. War reveals the ground, and philosophy repeats its generations, up to

---

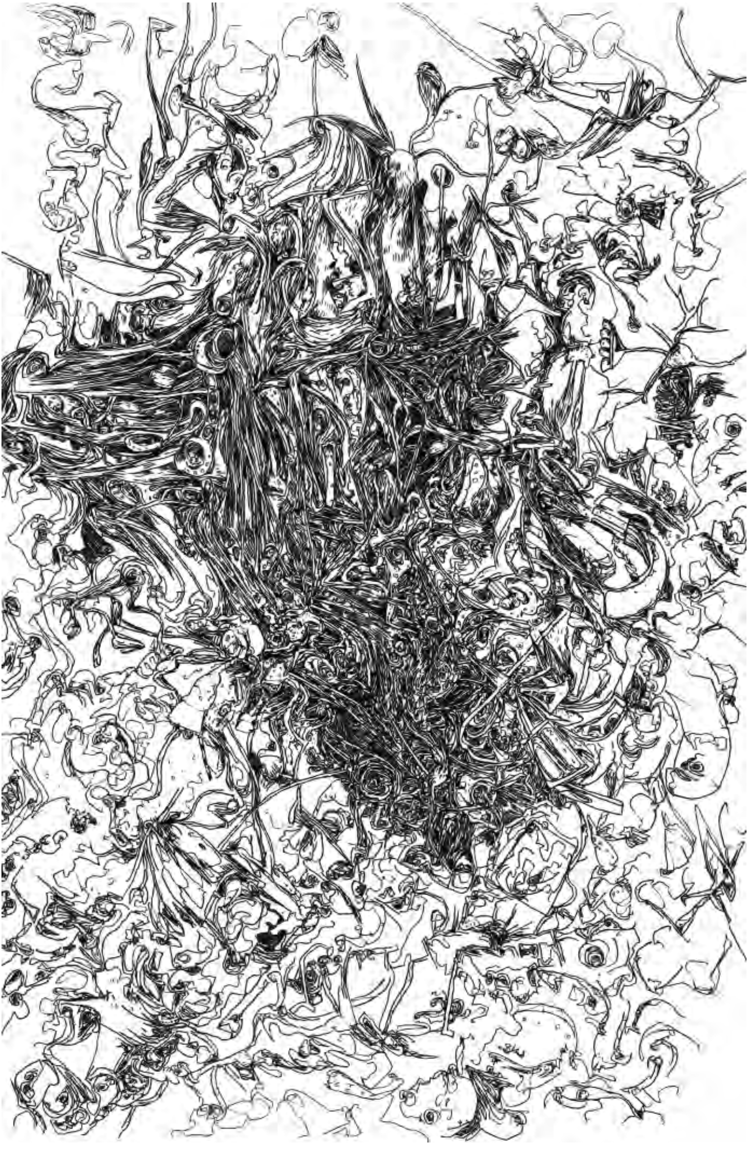
[78] *Elements,* 15-16.

[79] Ibid., 18.

[80] Ibid., 10.

[81] Ibid., 2.

[82] Ibid., 91.



and including its own generation in nature. Because ground supersedes its repetition, which precedes its revelation, an order of priority can be established *in thought*. Hence Oken: 'Time is the act of numbering; numbering is thinking; thinking is time'.[83]

This is not to argue that time exists *only* in thought, in the Kantian manner, but rather that, as Oken notes, thinking *is* time. This is because

> Time itself is only repetition […] The vicissitude of things is in fact time; if there be no change, there is also no time.[84]

In other words, because the grounding of existents consists in the repetition of zero, this grounding extends to Ideation, to philosophy. Philosophy is the *formal* repetition of cosmogony, while war is its *essential* repetition. Because Ideation is not itself the ground of time (Kant), but time that of Ideation, the grounding of existents in nothing establishes the a priority of nature with respect to mind, but without segregating mind from any part of nature or Mathesis. The principle of sufficient reason therefore states: *something emerges from nothing*, and this process is inviolable.

Oken's natural history of metaphysics therefore indicates that naturephilosophy is not simply *a* means, but the *necessary* means by which post-Kantian philosophy escapes the trap that the ethical process sets for it: the primacy of nature extends even to those slimy neural accretions to the primal Zero that make metaphysics possible.

On the Horror of Phenomenology: Lovecraft and Husserl

Graham Harman

In a dismissive review of a recent anthology on Schelling, Andrew Bowie accuses two authors of a style he 'increasingly' thinks of as 'continental science fiction'.[1] There is room for further increase in Bowie's thinking. With his implication that science fiction belongs to the juvenile or the unhinged, Bowie enforces a sad limitation on mental experiment. For nothing resembles science fiction more than philosophy does – unless it be science itself. From its dawning in ancient Greece, philosophy has been the asylum of strange notions: a cosmic justice fusing opposites into a restored whole; a series of emanations from fixed stars to the moon to the prophets; divine intervention in the movement of human hands and legs; trees and diamonds with infinite parallel attributes, only two of them known; insular monads sparkling like mirrors and attached to tiny bodies built from chains of other monads; and the eternal recurrence of every least event. While the dismal consensus that such speculation belongs to the past is bolstered by the poor imagination of some philosophers, it finds no support among working scientists, who grow increasingly wild in their visions. Even a cursory glance at the physics literature reveals a discipline bewitched by strange attractors, degenerate topologies, black holes filled with alternate worlds, holograms generating an illusory third dimension, and matter composed of vibrant ten-dimensional strings. Mathematics, unconstrained by empirical data, has long been still bolder in its gambles. Nor can it be said that science fiction is a marginal feature of literature itself. Long before the mighty crabs and squids of Lovecraft and the tribunals of Kafka, we had Shakespeare's witches and ghosts, Mt. Purgatory in the Pacific, the Cyclops in the Mediterranean, and the Sphinx tormenting the north of Greece.

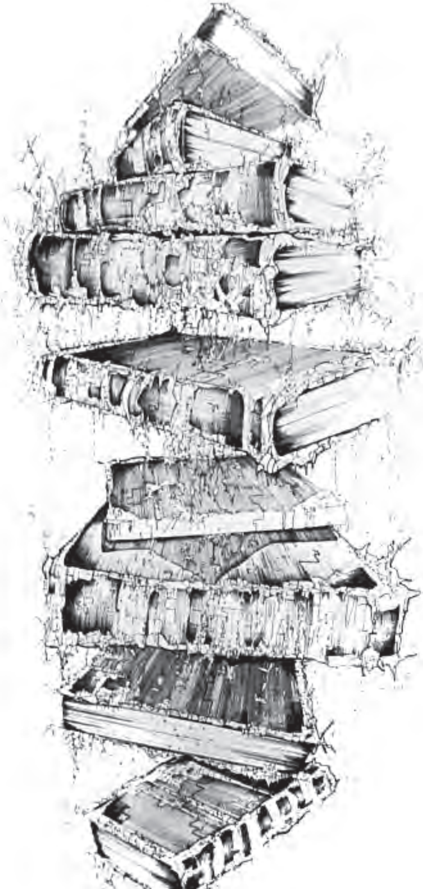
[1] Andrew Bowie, 'Something old, something new …', in *Radical Philosophy* 128 (November/December 2004), 46. The review is of *The New Schelling*, J. Norman & A. Welchman (eds.) (London: Continuum, 2004). The targets of Bowie's censure are Iain Hamilton Grant and Alberto Toscano.

Against the model of philosophy as a rubber stamp for common sense and archival sobriety, I would propose that philosophy's sole mission is *weird realism.* Philosophy must be realist because its mandate is to unlock the structure of the world itself; it must be weird because reality is weird. 'Continental science fiction', and 'continental horror', must be transformed from insults into a research program. It seems fruitful to launch this program with a joint treatment of Edmund Husserl and H.P. Lovecraft, an unlikely pair that I will try to render more likely. The dominant strand of twentieth-century continental thought stems from the



phenomenology of Husserl, whose dry and affable works conceal a philosophy tinged with the bizarre. In almost the same period, the leading craftsman of horror and science fiction in literature was Lovecraft, recently elevated from pulp author to canonical classic by the prestigious *Library of America* series.[2] The road to continental science fiction leads through a Lovecraftian reading of phenomenology. This remark is not meant as a prank. Just as Lovecraft turns prosaic New England towns into the battleground of extradimensional fiends, Husserl's phenomenology converts simple chairs and mailboxes into elusive units that emit partial, contorted surfaces. In both authors, the broken link between objects and their manifest crust hints at 'such terrifying vistas of reality, and of our frightful position therein, that we shall either go mad from the revelation or flee from the deadly light into the peace and safety of a new dark age'[3] – or preferably, revive a metaphysical speculation that embraces the permanent strangeness of objects. If philosophy is weird realism, then a philosophy should be judged by what it can tell us about Lovecraft. In symbolic terms, Great Cthulhu should replace Minerva as the patron spirit of philosophers, and the Miskatonic must dwarf the Rhine and the Ister as our river of choice. Since Heidegger's treatment of Hölderlin resulted mostly in pious, dreary readings, philosophy needs a new literary hero.

[3] Ibid., 167. From the famous first paragraph of 'The Call of Cthulhu.'

LOVECRAFT'S MATERIALISM

In the great tales of Lovecraft we find a mythology centered in New England, but ranging from the Antarctic to Pluto as well. Humans are no longer lords of the cosmos, but are surrounded by hidden monstrosities who evade or corrupt our race, sometimes plotting its downfall. 'The Old Ones', or 'Those Ones', are the disturbing general terms by which these creatures are known. They vastly exceed us in mental and physical prowess, yet occasionally interbreed with human females, preferring women of a decayed genetic type. The least encounter with the Old Ones often results in mental breakdown, and all reports of dealings with them are hushed. But their unspeakable powers are far from infinite. To achieve their aims, the Old Ones seek minerals in the hills of Vermont, infiltrate churches in seaport towns, and pursue occult manuscripts under the eyes of suspicious librarians. Their researches are linked not only with Lovecraft's fictional authors and archives (the mad Arab al-Hazred, Miskatonic University), but real ones as well (Pico della Mirandola, Harvard's Widener Library). Their corpses are carried away by floods, and even the mighty Cthulhu explodes, though briefly, when rammed by a human-built ship. There are also rivalries between the monsters, as becomes clear in 'At the Mountains of Madness'. The powers of the various Old Ones are no more uniform than they are infinite.

This balance in the monsters between power and frailty is mentioned to oppose any *Kantian* reading of Lovecraft. Such a reading is understandable, since Kant's inaccessible noumenal world seems a perfect match for the cryptic stealth of Lovecraft's creatures. His descriptions of their bodies and actions are almost deliberately insufficient, and seem to allude to dimensions beyond the finite conditions of human perception. His monsters are not just mysterious, but often literally invisible; they undermine our stock of emotional responses and zoological categories. The very architecture of their cities mocks the principles of Euclidean geometry. A few examples will indicate the style:

> When a traveler in north central Massachusetts takes the wrong fork at the junction of the Aylesbury Pike […] he comes upon a lonely and curious country […] Gorges and ravines of problematical depth intersect the way, and the crude wooden bridges always seem of dubious safety. When the road dips again there are stretches of marshland that one instinctively dislikes […][4]
>
> Odd wounds or sores, having something of the aspect of incisions, seemed to inflict the visible cattle […][5]
>
> [Wilbur Whateley] would sometimes mutter an unfamiliar jargon, and chant in bizarre rhythms which chilled the listener with a sense of unexplainable terror.[6]

And most compellingly:

> It would be trite and not wholly accurate to say that no human pen could describe [the dead creature on the floor], but one may properly say that it could not be vividly visualized by anyone whose ideas of aspect and contour are too closely bound up with the life-forms of this planet and of the three known dimensions.[7]

---

[4] Ibid., 370-1. Italics added.

[5] Ibid., 375-6. Italics added.

[6] Ibid., 379. Italics added.

[7] Ibid., 389. Italics added.

At the climax of 'The Dunwich Horror', when Curtis Whateley briefly glimpses the formerly hidden creature on the mountaintop, he describes it as made of squirming ropes, shaped somewhat like a hen's egg, with dozens of legs like barrels that shut halfway as it walks – a jelly-like creature having nothing solid about it, with great bulging eyes and ten or twenty mouths, somewhat grey in color with blue or purple rings, and a 'half-face' on top.[8] In the later tale 'At the Mountains of Madness', the vast Antarctic city displays 'no architecture known to man […] with vast aggregations of night-black masonry embodying monstrous perversions of known geometrical laws.'[9] When this dead metropolis is first sighted from the air, the narrator assumes it must be a polar mirage:

> There were truncated cones, sometimes terraced or fluted, surmounted by tall cylindrical shafts here and there bulbously enlarged and often capped with tiers of thinnish scalloped discs; and strange, beetling, table-like constructions suggesting piles of multitudinous rectangular slabs or circular plates or five-pointed stars […] There were composite cones and pyramids either alone or surmounting cylinders and cubes or flatter truncated cones and pyramids, and occasional needle-like spires in curious clusters of five. All of these febrile structures seemed knit together by tubular bridges […].[10]

The near-incoherence of such descriptions undercuts any attempt to render them in visual form. The very *point* of the descriptions is that they fail, hinting only obliquely at some unspeakable substratum of reality. It is obvious why this might seem Kantian in its implications.

---

[8] Ibid., 409-10.

[9] Ibid., 508.

[10] Ibid., 508-9.

Nonetheless, the Kantian reading fails. Even if we accepted a metaphysics splitting the world into noumenal and phenomenal realms, there is no question that the Old Ones would belong entirely to the phenomenal. The mere fact of invisibility is surely not enough to qualify the monsters as noumenal. The so-called Higgs boson of present-day physics, assuming it exists, lies beyond the gaze of current particle accelerators. No one has ever witnessed the core of the earth, or the center of the Milky Way which may or may not be home to a massive black hole. Countless other forces must exist in the universe that could be only decades away from discovery, while others will remain shielded from human insight in perpetuity. But this does not make them noumenal: these forces, however bizarre, would still belong to the causal and spatio-temporal conditions that, for Kant, belong solely to the structure of human experience. Let us grant further that the Old Ones may have features *permanently* outstripping human intelligence, in a way that the Higgs boson may not. Even so, this would be the result not of the transcendental structure of human finitude, but only of our relative stupidity. The game of chess is not 'noumenal' for dogs through their inability to grasp it, and neither is Sanskrit grammar for a deranged adult or a three-year-old. In 'The Whisperer in Darkness', the Old Ones even invite humans to become initiated into their larger view of the world:

> Do you realise what it means when I say that I have been on thirty-seven different celestial bodies – planets, dark stars, and less definable objects – including eight outside our galaxy and two outside the curved cosmos of space and time? […] The visitors are eager to know men of knowledge like yourself, and

> to shew them the great abysses that most of us have had to dream about in fanciful ignorance.[11]

Humans prepare to reach these deeper abysses, neither through Heideggerian *Angst* nor a mystical experience that leaps beyond finitude and reduces philosophy to straw, but through purely medical means: 'My brain has been removed from my body by fissions so adroit that it would be crude to call them surgery.'[12] The great horror of Lovecraft's universe lies not in some sublime infinite that no finite intelligence can fully grasp, but in the invasion of the finite world by finite malignant beings. For all the limits imposed on our intellect by Kant, he leaves us reassured that the finite and phenomenal world is insulated from horror, governed and structured by our own familiar categories. Far more troubling is Lovecraft's subversion of the finite world: no longer a kingdom led by innocuous rational beings, but one in which humans face entities as voracious as insects, who use black magic and telepathy while employing mulatto sailors as worse-than-terrorist operatives.

The Old Ones are anything but noumenal. Noumenal beings scarcely have need of buildings, whether Euclidean or otherwise. Noumenal beings are not dissected on the tables of polar explorers, do not mine for rocks in Vermont, and have no purpose mastering Arabic and Syriac dialects to consult the writings of medieval wizards. They would never speak in physical voices, not even with 'the drone of some loathsome, gigantic insect ponderously shaped into the articulate speech of an alien species […] [with] singularities of timbre, range, and overtones [placing it] wholly outside the sphere of humanity and earth-life.'[13] Michel Houellebecq, in a brilliant study of Lovecraft,[14] is correct to emphasize his absolute materialism: 'What is Great Cthulhu? An arrangement of electrons, like us. Lovecraft's terror is rigorously material. But, it is quite possible, given the free interplay of cosmic forces, that Great Cthulhu possesses abilities and powers to act that far exceed ours. Which*, a priori*, is not particularly reassuring at all.'[15]

---

[11] Ibid., 468.

[12] Ibid.

The terror of Lovecraft is not a noumenal horror, then, but a horror of phenomenology. Humans cease to be master in their own house. Science and letters no longer guide us toward benevolent enlightenment, but may force us to confront 'notions of the cosmos, and of [our] own place in the seething vortex of time, whose merest mention is paralysing', and 'impose monstrous and unguessable horrors upon certain venturous [humans]'.[16] Confronted with the half-human offspring of the Old Ones, even the political Left will endorse the use of concentration camps: 'Complaints from many liberal organizations were met with long confidential discussions, and representatives were taken on trips to certain camps and prisons. As a result, these societies became surprisingly passive and reticent'.[17]

16. Ibid., 719. From 'The Shadow Out of Time.'

17. Ibid., 587. From 'The Shadow Over Innsmouth.'

To expand on a passage cited earlier:

> The most merciful thing in the world, I think, is the inability of the human mind to correlate all its contents. We live on a placid island of ignorance in the midst of black seas of infinity, and it was not meant that we should voyage far. The sciences, each straining in its own direction, have hitherto harmed us little; but some day the piecing together of dissociated knowledge will open such terrifying vistas of reality, and of our frightful position within, that we shall either go mad from the revelation or flee from the deadly light into the peace and safety of a new dark age.[18]

---

[18] Ibid., 167.

Though ostensibly Kantian on a first reading, nothing could be less Kantian than this passage in its call for barriers to enlightenment, and its placement of 'terrifying vistas' not in some transcendent sublime, but in the electrons that form the pulpy torso of Great Cthulhu.

THE WEIRDNESS OF OBJECTS

The literary critic Harold Bloom shares the following anecdote:

> Some years ago, on a stormy night in New Haven, I sat down to reread, yet once more, John Milton's *Paradise Lost* […] I wanted to start all over again with the poem: to read it as though I had never read it before, indeed as though no one had ever read it before me […] And while I read, until I fell asleep in the middle of the night, the poem's initial familiarity began to dissolve […] Although the poem is a biblical epic, in classical form, the peculiar impression it gave me was what I generally ascribe to literary fantasy or science fiction, not to heroic epic. *Weirdness* was its overwhelming effect.[19]

Science fiction is found not only in 'science fiction', but in great literature of any sort. More generally, Bloom contends that 'one mark of an originality that can win canonical status for a literary work is a *strangeness* that we either never altogether assimilate, or that becomes such a given that we are blinded to its idiosyncracies.'[20] Although Bloom has little time for philosophy, which he views as cognitively less original than literature, his standard of canonical achievement seems equally valid for philosophical work. If there is one feature that unites the great works of philosophy, it is surely their inability to be fully assimilated, or their tendency to become such a given that we are blinded to their strangeness. Though Plato and Kant can be seen as restrictive establishment figures, their works are saturated with deviant images and nearly fantastic concepts; they exceed all possible interpretation, resist all attempted summary, and appeal to readers of any nationality or political orientation. The education of young philosophers builds on these works as on bedrock. And they come alive only when some gifted interpreter rediscovers their strangeness.

---

[19] Harold Bloom, *The Western Canon*, 24-5. (New York: Riverhead Books, 2004). Italics added.

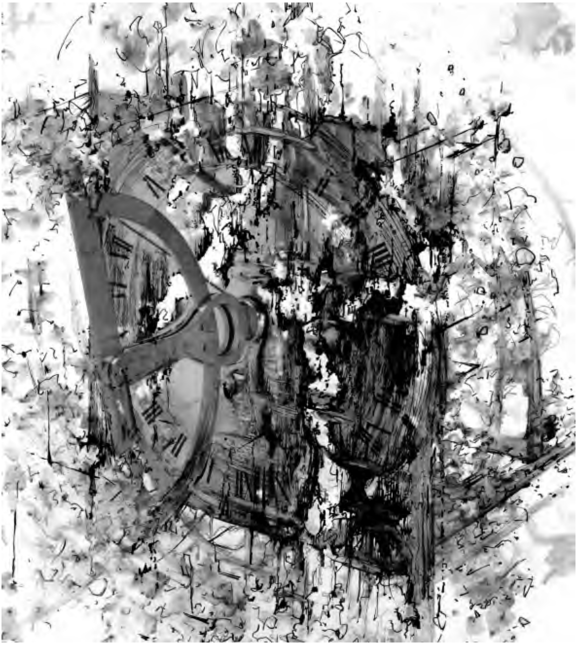
[20] Ibid., 4.

Pressing further, it also seems evident that the strangeness of works comes less from the works as a whole than from the weirdness of the personae that fill them, whether in literature, philosophy, or science. Though Don Quixote and Lear's Fool appear solely in literary works, they are no more reducible to extant plot lines than our friends are exhaustively grasped by our dealings with them. Characters, in the broadest sense, are *objects*. Though we only come to know them through specific literary incidents, these events merely hint at a character's turbulent inner life – which lies mostly outside the work it inhabits, and remains fully equipped for sequels that the author never produced. If a lost Shakespearean tragedy were discovered, dealing with the apparent suicide of the Fool (who disappears without explanation from the existing text of *King Lear*), the same Fool would have to be present in the new work, however unexpected its speeches. The same is true of philosophical concepts, which must also be viewed as characters or objects. While recent philosophy insists on precise definitions of every term, a genuine philosophical concept always eludes such precision. We could list the known features of Leibniz's monads in a laminated chart, yet the list includes contradictions, and surely leaves us hungry for more. The same holds true of argon in chemistry or the string in physics. A thing cannot be reduced to the definitions we give of it, because then the thing would change with each tiny change in its known properties, as Kripke has sharply objected.[21] A good rule of thumb is as follows: *unless* a character gives rise to different interpretations, *unless* a scientific entity endures changed notions of its properties, *unless* a philosopher is entangled in contradictory assertions over one and the same concept, *unless* a new technology has unforeseen impact, *unless* a politician's party is one day disappointed, *unless* a friend is able to generate and experience surprises, then we are not dealing with anything very real. We will be dealing instead with useful surface qualities, not with objects. Let 'object' refer to any reality with an autonomous life deeper than its qualities, and deeper than its relations with other things. In this sense, an object is reminiscent of an Aristotelian primary substance, which supports different qualities at different times. Socrates can laugh, sleep, or cry at various moments while still remaining Socrates – which entails that he can never be exhaustively described or defined.

My thesis is that objects and weirdness go hand in hand. An object partly evades all announcement through its qualities, resisting or subverting efforts to identify it with any surface. It is that which exceeds any of the qualities, accidents, or relations that can be ascribed to it: an 'I know not what', but in a positive sense. Against frequent efforts to dismiss objects as fantasies assembled by humans from a pre-given surface of experienced contents, I contend that reality is object-oriented. Reality is made up of nothing but substances – and they are *weird* substances with a taste of the uncanny about them, rather than stiff blocks of simplistic physical matter. Contact with reality begins when we cease to reduce a thing to its properties or to its effect on other things. The difference between objects and their peripheral features (qualities, accidents, relations) is

---

[21] Saul Kripke, *Naming and Necessity*. (Cambridge, MA: Harvard Univ. Press, 1996).



absolute. Though this thesis is deeply classical, it cannot possibly be 'reactionary', since the objects of which I speak resist all reduction to dogma, and in fact are the only force in the world capable of doing so.

INTENTIONAL OBJECTS

Few will object to the term 'weird realism' as a description of Lovecraft's outlook. *Weird Tales* was the periodical that spawned his career, and 'weird fiction' the term most often used for his own writings. Lovecraft was opposed to realism in the literary sense of James or Zola, their minute descriptions confined to the subtleties of human life. Yet he seems like a realist in the philosophical sense, hinting at dark powers and malevolent geometries subsisting well beyond the grasp of human life. By contrast, Edmund Husserl seems to be neither weird, nor a realist, and even looks like the opposite: a 'non-weird antirealist'. No reader, however emotionally unstable, is terrified by Husserl's works. Even in his life history, the sufferings we find stem from personal and political burdens, not from the family strain of madness that paralyzed the young Lovecraft and destroyed his parents. Moreover, when phenomenology is critiqued or abandoned, this is usually because of its wholehearted idealism. All of phenomenology results from a decision to 'bracket' the world, suspending reflection on real waves, genes, and chemicals in favor of what lies entirely within human consciousness. Ironically, this point has led some to compare Husserl with Kant as well. Here the comparison fails yet again, but for the opposite reason: while Lovecraft's monsters are too shallow to be noumenal, Husserl's intentional objects are too deep to be purely phenomenal.

Husserl often proclaimed his motto: ‘to the things themselves’. Though the phrase is partly misleading, it should be taken more seriously by those realists who find little of value in his thought. The first step is to remember that Husserl’s ‘things themselves’ are obviously not meant in the Kantian sense. His bracketing of nature leaves him with an immanent world of pure experience. Description (not *explanation*, as with realists) is taken to be the sole philosophical method. Furthermore, there is no room in Husserl for real things that might be viewed directly by God and that lie outside the parameters of human access to the world. All of this might seem to lead to a mere flattening of the noumenal into a special case of the phenomenal, as found in Fichte and his heirs. In his ontology, Husserl would seem to belong to the tradition of German Idealism; his own student Heidegger sometimes makes this claim, hinting vaguely that Husserlian phenomenology is the same basic project as Hegel’s *Science of Logic*. Some observers might even be seduced by the recurrence of the term ‘phenomenology’ in both Husserl and Hegel.

But despite Husserl’s fixation on the immanent world of appearance, he injects a dose of obstinate reality into the immanence. This occurs through his notion of intentional objects. The principle of intentionality is well-known: every mental act has some object, whether it be thinking, indicating, wishing, judging, or hating. This principle has not been correctly understood. It does not mean that Husserl somehow escapes idealism: his intentional objects remain purely immanent, and must not be confused with real forces unleashed in the world. The trees I perceive, the food I enjoy, or the swindlers I despise, remain phenomenal entities. After all, their real existence is bracketed, so that our description of them takes no account of whether they truly exist. Intentionality remains phenomenal. But Husserl's genuine difference from the idealists lies in the fact that intentional reality is made up of *objects*, which play no role at all for Fichte or Hegel. It is said that Husserl would lead his students through painstaking descriptions of a mailbox; perhaps on other days it was lampposts, inkwells, cats, rings, or vases. The point of such descriptions was 'eidetic variation', considering these objects from a variety of angles so as to approach their unvarying *essence* beneath all passing manifestation. The mere fact that intentional objects have an essence should prevent our seeing Husserl as a straightforward idealist, since 'essence' is normally a realist term, linked with the inherent features of a substance apart from all access to it. It is unthinkable that Fichte or Hegel would guide their students through minute descriptions of a specific solid object, since in their current of thinking objects have no stubborn essence of their own. 'Essence', for Hegel, is sublated into the higher unity of the concept, and Hegelians even like to accuse later continentals of a fixation on essence. By contrast, though Husserl brackets the world in order to focus on an immanent field of consciousness, the ego is not entirely master in this immanent realm. Cats and lampposts resist our first approach, demanding patient labours if their essence is to be gradually approached. While the shadows in Heidegger's thought lie buried beneath perception, Husserl's mysteries riddle the field of perception itself. Yet both thinkers allow for secrets to be harboured in the core of the things, and this is what separates them from idealism. Despite their regrettable focus on human reality, Husserl and Heidegger are object-oriented philosophers.

In one sense Husserl's obvious rival is psychologism, which holds that logical laws have only psychological validity. Husserl assaults this position in his massive prologue to the *Logical Investigations*, concluding that logic is objective through its ideal validity within the phenomenal realm. But an equally important rival is British Empiricism. *Logical Investigations* II is a detailed critique of the positions of Locke, Berkeley, and Hume. For all the differences between these three classic figures, it is safe to portray them as allied in advance against intentional objects. What comes first for the empiricists are isolated *qualities*, sometimes known as 'impressions.' By contrast, the tradition of phenomenology begins not with qualities, but with phenomenal *objects*. While the British school holds that objects are a bundle produced through the habit of linking diverse qualities together (Hume), or by imagining that hidden powers underlie qualities already seen (Locke), phenomenologists such as Husserl and Merleau-Ponty insist on beginning with the total *Gestalt* before any reduction to discrete tones and hues. For phenomenology, the slamming door and the black fountain pen precede their qualities, which gain sense only through a relative enslavement to those objects. Herein lies the greatness of phenomenology, which is more empirical than the empiricists. Experience is not of 'experienced contents', but of objects; isolated qualities are found not in the world we experience, but only in the annals of empiricism.

In *Logical Investigations* V, the rival is Husserl's own teacher Brentano, whether fairly or not. If Brentano held that all mental acts are grounded in some sort of presentation, Husserl twisted the formulation slightly, countering that

all mental acts are *object-giving*. The difference is subtle, but fateful. A presentation seems to put all its contents on the same footing. To represent a globe or a tower is to witness a specific configuration of colors, textures, shadows, and physical co-ordinates. But if we see experience as object-giving rather than presentational, we shift our focus toward the essential nucleus of the perception, stripping the paint and confetti from its outer shell through eidetic variation. And here we find the crucial difference between Husserl's intentional objects and the real objects of realist philosophers. Real objects, which play no role in the bracketed thinking of Husserl, subsist apart from their relations to anything else; no reality could be independent if it were generated by efforts to perceive or influence it. In this sense, it seems obvious that real objects must partly withhold themselves from all perception, description, registration, or cataloguing of their traits. A substance simply is what it is, and exceeds the endless summation of qualities that can be ascribed to it. But strangely enough, this is not true of Husserl's intentional objects, where an inverse relation holds. Without belabouring a point made elsewhere,[22] whereas real objects taunt us with endless withdrawal, intentional objects are always already present. A real tree would be deeper than anything that can be said or known about it, but the tree of intentional experience is entirely present from the start – it is always a genuine element of experience, affecting my decisions and my moods. If the real tree is never present enough, the intentional tree is always *excessively* present, its essence accompanied by the noisy peripheral detail that eidetic variation needs to strip away. The real object 'fire' is able to scald, burn, boil, melt, and crack other real objects, while the intentional object 'fire' has a very different function: it merely unifies a shifting set of profiles and surfaces whose various flickerings never affect its ideal unity. Real objects hide; intentional objects are merely weighed down with trains of sycophantic qualities, covering them like cosmetics and jewels.

---

THE WEIRDNESS OF HUSSERL

The strangest defect of the books that Husserl published during his lifetime lies in how few descriptions they actually contain. Whatever he may have done in the classroom, one scours his principal works in vain for more than a handful of concrete examples. Husserl seemed content, in his major published writings, with hesitant manifestoes for phenomenology; Merleau-Ponty and Lingis, heirs of greater stylistic gifts, were left to put the method to the test. Consider the case of some massive artifact – say, a hotel complex such as the Nile Hilton, in my adopted home city. The phenomenologist might see it as follows: The hotel is not an arbitrary conglomerate pieced together from flecks of color and sound. What we first encounter is the hotel as a whole, its visible profiles all joined in allegiance to the total reality of the object. Observers may disagree over the exact boundaries of the facility, over where its style begins and ceases to reign, but all will agree that the hotel is present in consciousness as a unit. The various doors, plants, gates, windows, and guards are clearly imbued with a kind of hotel-being, since all would strike us quite differently if stripped from this zone and encountered elsewhere. We now circle the hotel, soaking up the feel of its various entryways: grand entrance in front, dusty two-guard access in back, glamorous terraces when viewed from the south at a distance, and grim windowless façade to the north. We explore the interior, passing from food court to travel agencies to weight room to rooftop lounge, finally knocking on random doors and asking to examine individual rooms. Never in these movements do we see the whole of the Hilton, yet never do we lose the sense of a general *style* to which the individual scenes belong. It is not important that moths and beetles would not also see it as a 'hotel', since we are dealing here not with objective reality, but only with our human *intention* of the hotel as a unified whole. Normally, we make no separation between an intentional object and the surface features through which it is announced. Though we only see one face of the hotel at a time, the presence of hotel and surface seem to be simultaneous, and joined together without fissure.

Yet this intimate bond between object and quality is an illusion, as both Husserl and Lovecraft are aware. Let's begin with a Lovecraftian version of the hotel. This requires an attempt to mimic his own literary style – a method of reverent parody that deserves to become a staple of philosophy. The following paragraphs might be found in an unwritten Lovecraft tale, 'The Nile Hilton Incident':

> Though apparently of recent date, the Nile Hilton is built around strange inner corridors of disturbingly ancient provenance. Its membership in the Hilton chain, meant to reassure travelers from the Occident, conceals grotesque legal maneuvers and deviant managerial practices of a purely local origin, and provides cover for a dubious history long expunged from brochures. The doormen are slumped and sullen in a manner atypical of Egypt, while their complexions speak vaguely of a strange admixture of Aztec and Polynesian blood not consonant with the known history of the city.
>
> Unnoticed by the casual witness, the building itself embodies subtle though monstrous distortions of sound engineering principle. Though the outer walls seem to meet at solid right angles, the hue of the concrete departs from accustomed values in a manner suggestive of frailty or buckling. The gaping air-shafts are striking for an edifice of such late construction, and

> seem fitted to an age when consumption and leprosy were still in abundance. For unknown reasons, several of the fire escapes would appear to issue beneath the surface of the ground. And though the rear façade displays no evident structural flaws, there is a sense of looming collapse in the area; one arising less from visual clues than from certain peculiarities of sound and odour which the management has refused to acknowledge. It is here that a faint but incessant thumping or scraping noise is combined with a scent joining the aroma of sandalwood to one oddly reminiscent of the corpses of bovines. In response to occasional complaints, the concierge makes ostentatious show of despatching inspectors; yet something in the *rhythm* of his response gives the unwonted impression of deceit.

Presumably, Merleau-Ponty was never a reader of Lovecraft. This is unfortunate, since their methods of description have a great deal in common. Although we normally encounter things clothed in a variety of costumes, we pass silently and directly through these garments to the thing as a whole, which seems to imbue them with its spirit. But in Lovecraft, the relation between a thing and its surface is perturbed by irregularities that resist immediate comprehension, as if the object suffered from a strange disease of the nervous system. In real life, an Egyptian doorman is usually found in a cheerful and careless pose, displaying the typical physiognomy of the southern populations of Aswan and Luxor. To describe him instead as 'slumped and sullen', as displaying racial features of distant or extinguished peoples, and especially to call attention to one's perplexity over these aberrations, leads to a breakdown in the usual immediate bond between the doorman and his qualities. A rare fissure is generated between the object and its traits. Although 'Egyptian doorman' remains a legitimate element of our experience, he is now a menacing kernel that seems to control his outer features like ghastly marionettes, rather than being immediately fused with them. Merleau-Ponty would agree that the durability of concrete is somehow legible in its colour, though the total emotional and perceptual effect of a wall is normally simultaneous and unified. But to suggest that something is amiss in the expected colour of a wall, something that faintly suggests imminent physical breakdown, is to decompose the usual bond between the phenomenon and the outer forms through which it is announced. Language is also able to hint at depth, at real things lying outside all access to them. Surprisingly, this is not the method of Lovecraft, whose materialism gives him a philosophy rooted in the surface, but one in which the relation between objects and their crusts is rendered problematic. His monsters are not deep in themselves, and function in his stories only to disturb the assumptions of human observers. One can imagine third-person tales of the Old Ones battling in outer space, aeons before the emergence of human beings. Such stories would yield more of fantasy than of horror, since we would miss the gradual awareness of human subordination that provides the Cthulhu mythos with its terror. There is nothing inherently compelling about a humanoid dragon with an octopus for a head; any teenager could draw such a thing, while scaring no-one. The horror comes instead from the declared insufficiency of the description, combined with a literary world in which this monster is a genuine player rather than a mere image. The description is horrific only insofar as it undermines any distinct image: 'If I say that my somewhat extravagant imagination yielded simultaneous pictures of an octopus, a dragon, and a human caricature, I shall not be entirely unfaithful to the spirit of the thing. A pulpy, tentacled head surmounted a grotesque and scaly body with rudimentary wings; but it was the *general outline* of the whole which made it most shockingly frightful.'[23] Whatever this 'general outline' may be, the narrator feels that his descriptions are at best 'not entirely unfaithful' to its spirit. But this is the very principle of phenomenological description, whose eidetic reductions never quite grasp the essence of the thing, and which differs from Lovecraft only in its usual avoidance of the theme of existential threat. In both cases, the known link between objects and their properties partially dissolves.

---

[23] Lovecraft, *Tales*, 169. From 'The Call of Cthulhu.'

While there are palpable similarities between Lovecraft and Poe in their preference for moods of horror, too little has been said about their similarities of style. In both authors we find hesitant and flowery wording that not only paints their narrators as frail aesthetes, but effectively stunts the relation between things and their traits. In Poe's tale 'The Fall of the House of Usher', the narrator describes Roderick as having 'a nose of a Hebrew model, but with a breadth of nostril unusual in similar formations; a finely moulded chin, speaking, in its want of prominence, of a want of moral energy.'[24] To claim directly that there is a typical Jewish nose with a specific nostril size, or that the character of a person can be read from structures of the skull, would merely make one a racist and a phrenologist. But Poe's strange appeal to unexpected disproportions of nostril and chin manages to disassemble the complex amalgam of surface and inference that silently accompanies every new face. To say that Roderick can bear no sounds except the music of guitars would merely give an eccentric description, not a horrific one. The terror comes instead through Poe's meandering way of depicting the trait: 'there were but peculiar sounds, and those from stringed instruments, which did not inspire him with horror.'[25] Roderick's panpsychist theory of inanimate perception might be just a vitalist platitude if stated in a journal article. Yet Poe surrounds the idea with enlivening obstacles: 'His opinion, in its general form, was that of the sentience of all vegetable things. But, in his disordered fancy, the idea had assumed a more daring character, and trespassed, under certain conditions, upon the kingdom of inorganization.'[26] The phrasing should not be dismissed as belonging to a lost era of florid English style; the circumlocution is deliberate, and creates a gap between object and profile that is concealed in everyday experience. The same holds for the narrator's description of Roderick's macabre painting of an underground tunnel, in which 'certain accessory portions of the design served well to convey the idea that this excavation lay at an exceeding depth below the surface of the earth'.[27] And finally, Poe's descriptions of music are as impossibly vague as Lovecraft's stunted polar travel diaries. Foremost among Roderick's improvisations on the guitar is 'a certain singular perversion and amplification of the wild air of the last waltz of von Weber'.[28] If a musicologist were to specify the precise distortions of Roderick's melodies in a report commissioned by psychiatrists, or if we heard a recorded version of the music, the effect would be ruined. The point is not to pin down his exact deviations from mainstream musical practice, but to hint that something is terribly amiss in the relation between the music and its exact tones.

---

[24] Edgar Allan Poe, *Poetry and Tales*, 321. (New York: Library of America, 1984.)

[25] Poe, *Poetry and Tales*, 322.

In Lovecraft as in Poe, the horror of things comes not from some transcendent force lying outside the bounds of human finitude, but in a twisting or torsion of that finitude itself. The immediate fusion between a thing and its tangible signals gives way to the detachment of a tortured underlying unit from its outward qualities. In similar fashion, cubist painting renders its figures paradoxically

---

[27] Ibid., 325.

[28] Ibid., 324.

distinct from the amassing of planes and angles through which they are presented. It is no accident that only certain paintings by Georges Braque seem to approach a notion of what Lovecraftian architecture might look like,[29] and surely no accident that Ortega y Gasset links Husserl with Picasso.[30] That said, we should turn briefly from Lovecraft and Poe to the Husserlian version of cubism.

---

[29] Among other instances, see Braque's 1908 canvas 'House at l'Estaque', best viewed in conjunction with Lovecraft's description of the Antarctic city.

[30] José Ortega y Gasset, 'On Point of View in the Arts', trans. P. Snodgress and J. Frank. In *The Dehumanization of Art* (Princeton, NJ: Princeton Univ. Press, 1968), 129-130.

What is most disturbing about intentional objects is that they are both *always* and *never* present. Husserl established that the field of perception is made up of objects, not sense data. Yet hotels, museums, and trees require the most laborious work of eidetic variation to free them of all noise, and even this method never succeeds. The hotel is present from the start, yet we never reach a truly exemplary vision of it, free of environmental accident. Nor are these accidents ever directly present. As soon as we shift our focus from the hotel as a whole to the peripheral dance of light along its façade, we have turned sunbeams or moon-rays into our new intentional object, and the eidetic reduction will now be blocked by further shimmering variations that do not affect the beams or rays as a whole. Intentional objects are everywhere and nowhere; they 'bubble and blaspheme mindlessly' at every point in the cosmos. Although vividly present as soon as we acknowledge them, intentional objects express their reality only by drawing neighboring objects into their orbit, and these things in turn are only present by enslaving still others. As Merleau-Ponty first observed, the structure of perception is not obvious in the least. There is no such thing as a directly given experience. Even less directly given would be the real objects lying outside all intentional experience, bracketed by Husserl and hence not considered in this article. Just as Lovecraft's horror has nothing to do with transcendent things themselves, the horror of phenomenology arises even though all transcendent reality is suspended. Lovecraft's heroes cannot maintain their faith in the familiar contract between things and their properties, since the creatures they encounter are never quite captured by any list of tentacles or strange vocal timbres. A weird reading of phenomenology (the only possible reading) loses faith not just in the given sense data of empiricists, but even in the clean separation between objects and qualities. What is present is never objects or qualities, but only a fission between one object and the satellite objects bent by its gravitational field, even if everyday perception deadens us to this fact.

Without having even considered the status of *real* objects, we find that intentional objects already have a weirdness that eludes definition. It is often falsely held that phenomena have definite qualitative features, which is the position of empiricism, not of Husserl. It is held even more widely, and just as falsely, that real objects must have definite material features and exact positions in space-time. These views form the apparent motive for recent philosophies of 'the virtual.' If real and intentional objects are both somehow actual, both fully enshrined in the world in a manner that could in principle be described, then both seem fully inscribed in a context or web of mutual interrelations. And since true realism requires that things be considered apart from all relations, the only solution would be to shift the scene of realism away from concrete objects and phenomena towards disembodied attractors, topological invariants, or other virtual entities, all of them outstripping any possible embodiment in specific entities.[31]

What this step misses is the already abominable weirdness of concrete objects, whether real or phenomenal. But Lovecraft and Husserl do not miss this point. Though the materialism of Lovecraft and the idealism of Husserl might seem to divide them, these doctrines go hand in hand. For we are never really sure just what an object is. Whether we define it as nothing more than electrons, or as just a shape present in consciousness, we replace the fathomless reality of things with an intellectual model of what their underlying reality ought to be. In this sense, realism tends to oppose the outlooks of Lovecraft and Husserl. Yet in a different sense, they save the weirdness of objects from its neglect by philosophies of the virtual. While such philosophies may deserve admiration for insisting on realism against any idealism or narrowly physical materialism, they are wrong to hold that objects are always utterly specific. Lovecraft (surprisingly) and Husserl (unsurprisingly) remain fixed on a material/phenomenal plane that prevents them from being full-blown metaphysical realists. But at least they grasp the weird tension in the phenomena themselves, always in tense dissolution from their qualities. It is a one-legged realism that misses the genuine hiddenness of things, but a weird realism nonetheless.

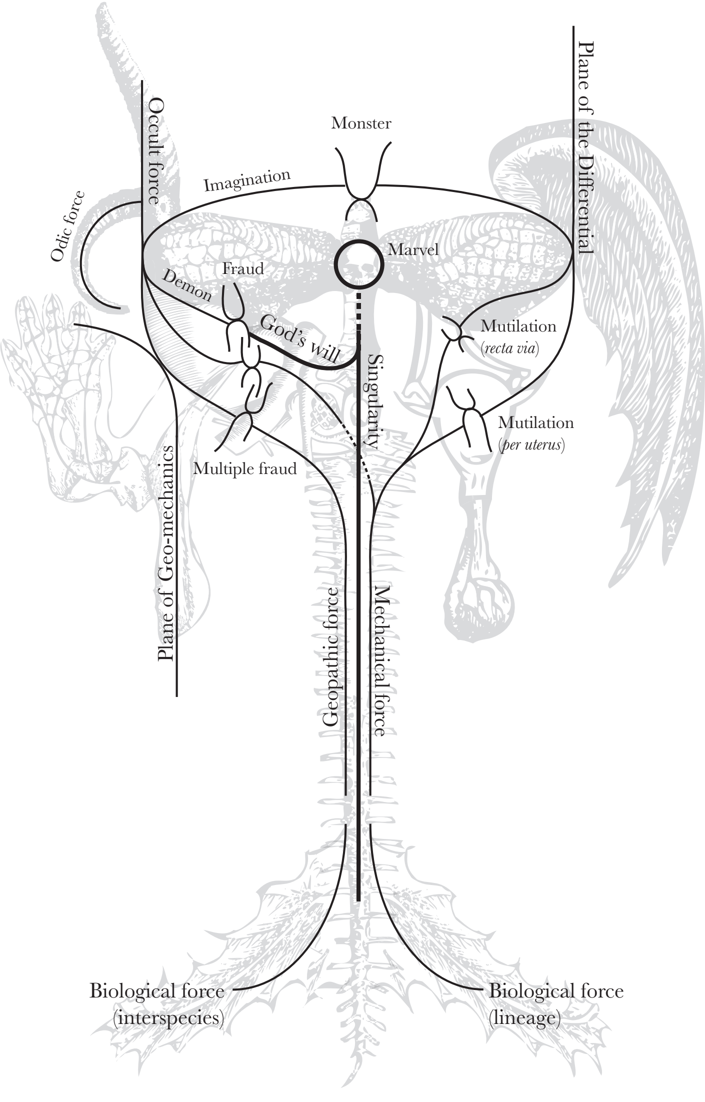
Arbor Deformia

Kristen Alvanson

Among manuscripts published and treatises written on teratology and cryptozoology, one work has been more influential than others: Ambroise Paré's *Des monstres et des prodiges*, written in the sixteenth century. Paré was a distinguished French surgeon, the royal surgeon of Henry II, Francis II, Charles IX and Henry III. *Monsters and Prodigies* was penned by Paré at the peak of the sixteenth-century teratological frenzy inherited from the occult and medical preoccupations of the Middle Ages. Written toward the later stages of his professional life as a surgeon, *Monsters and Prodigies* is a monstrous paean to arborescent models of taxonomy. For Paré, as a scientist who believed that his teratologic treatise should be incorporated with his works on surgery and practical medicine, the problem of taxonomy is more twisted and deformed than monsters and deformities themselves. Problems inherited from the Middle Ages concerning theological riddles, occult forces and fantastic fauna cannot easily be reconciled with Renaissance solutions. Therefore, for Paré what is deemed as truly monstrous is taxonomy itself: *How is it possible to build a monstrous order or taxonomy to bring all fiends, rogue beings, demonic deformities and divine marvels back into the fold?*

ARBOR DEFORMIA



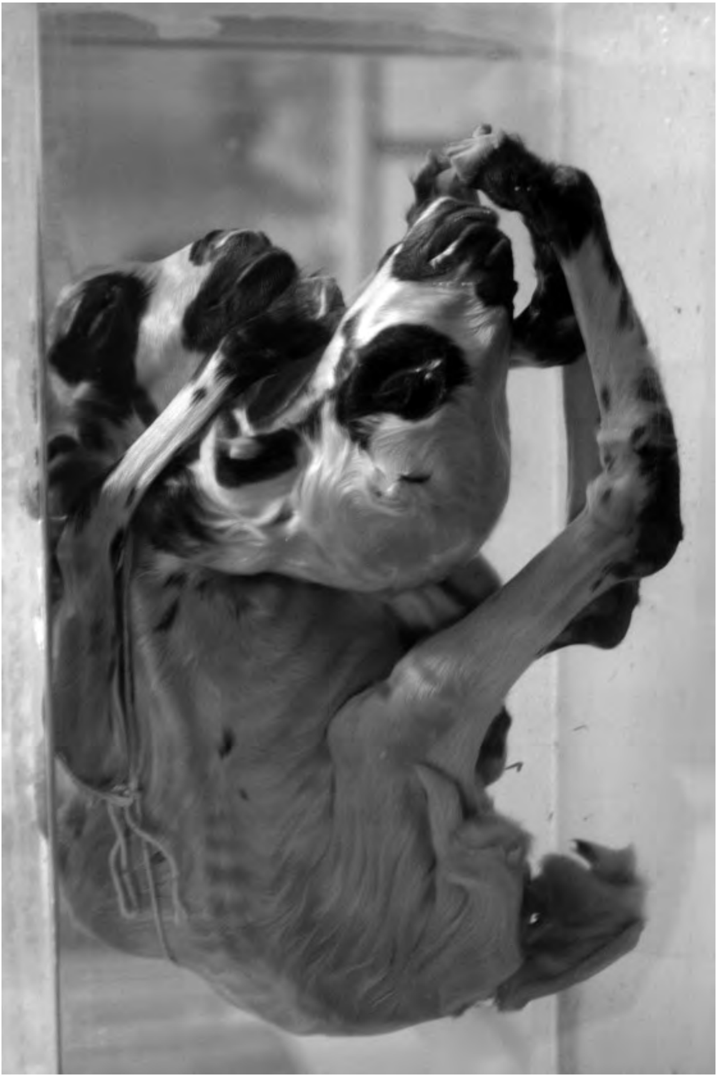
Monster
Imagination
Occult force
Plane of the Differential
Odic force
Marvel
Fraud
Demon
God's will
Singularity
Mutilation
(*recta via*)
Mutilation
(*per uterus*)
Multiple fraud
Plane of Geo-mechanics
Geopathic force
Mechanical force
Biological force
(interspecies)
Biological force
(lineage)

'Taxonomy as monstrous', 'hierarchy as deformity', 'category as schizophrenic order' and 'tree as *lusus naturae*' could all stand as partial characterisations of Paré's teratological system. In order to tackle the enigma of deformities, monsters and prodigies once and for all, Paré creates a paraphysical model in which (I) Singularity, (II) planes and (III) forces are the main components from which to concoct a taxonomic system. Forces derive from different fields or spheres and vary from occult-paranormal to mechanical-physical forces; in Paré's system, most of the taxonomies evolve out of interactions between these elements. These interactions include the application of forces to planes, the fusion of forces with each other or the conflict of certain forces with singularity. However, the force of Godhead or singularity is capable of developing taxonomies on its own. These elements can produce thirteen causes which incite abnormalities. Further classifying, Paré divides these causes into another four groups based on which deformities are identified: (i) marvellous causes, (ii) monstrous causes, (iii) mutilating causes and finally (iv) fraudulent causes. Marvelous causes are those which belong to the direct intervention of God and are divided into (1) wrath and (2) glory of God. Monstrous causes originate from the fusion of different forces or the application of different forces to certain planes; they are (3) too many seeds, (4) too little seed and (5) maternal imagination during pregnancy. Mutilations are mostly brought forth by the application of mechanical forces either directly to the embryo or through the womb; the rest originate from biological forces which themselves are divided into two sources, interspecies and hereditary. Mutilations include (6) deformity or smallness of the womb, (7) bodily postures of the mother during pregnancy, (8) unnatural pressure,

blows or even a blast of air to the womb, (9) hereditary or accidental illnesses, (10) rotten seed, (11) mingling of seeds belonging to different species. The fourth category of causes, fraudulent causes, are strictly related to occult forces: (12) through the artifice of wicked beggars, (13) demons and the Devil himself. Among these thirteen causes, 11 and 13 can form a categorical alliance – causes by unnatural conceptions (13a). The causes involving seeds (3, 4, 10, 11) can merge together to compose yet another offshoot, causes by unnatural seeds (13b). In this manner, Paré continues to add more branches, stems, branchlets, twigs and unnatural fruits to his taxonomy. Although Paré briefly touches on African and oceanic monsters, he emphasizes that the origin of monsters should be left hidden, referring to the cryptogenic essence of the monstrous.

The *Arbor Deformia* (see p.368) is a schematic designed after the Paréan system of teratological taxonomy. Taking taxonomy as the monstrous idea inclusive of all monsters and deformities, the *Arbor Deformia* is an arborescent model in the tradition of the early trees of knowledge, elements, demons and celestial bodies. The *Arbor Deformia* follows the tradition of arborescent distributions where the idea of the tree is the ratio of two operations, contraction and expansion, represented by two folds, roots and branches. In early arborescent models the tree is not a dichotomous totality but a proportional relation between the underground and elevated activities; it is also the perpetuation of asymmetries or deformities in symmetry or form. The non-dichotomous relation between the root and the branch is typified by the trunk as the middle-ground part of the model. Given that the tree is a ratio between underground and elevated activities, it can be infinitely deformed without losing its defining outlines. As a part of the ratio between roots and branches, new changes can be made within the existing range which is marked by the two poles, roots and branches. This enormous capacity for deformation is exemplified in the image of hollow trees. Hollow trees frequently appear in illustrations and paintings of the *Grotteschi* style, Arabesque–inspired ornamental engravings of the sixteenth century, not to mention the dead elm trees that feature in Italian Renaissance paintings. A thirteenth-century engraving from the *Ornamentale Vorlage-Blätter* made by the Flemish sculptor and draughtsman Cornelis Floris II depicts a tree which is not a tree, but a sport of nature. Alluding to the forbidden fruit of the Garden of Eden, Floris' tree is in the shape of a fruit bursting open with demons, monsters and serpents. It is a hollowness which only in appearance bears the burden of its tree-ness.

New forces and planes have been added to *Arbor Deformia* to include those causes of deformities which are absent in Paré's taxonomy. *Arbor Deformia* is comprised of five forces and two planes. Forces include (1) hereditary biological forces, (2) inter-specific biological forces, (3) mechanical forces, (4) occult forces, and (5) geopathic forces. The plane of the differential and the plane of geo-mechanics are the receptive planes for forces. The plane of geo-mechanics is not directly involved in producing deformities and monsters, but connects two different forces which can cause abnormalities: The plane of the differential expresses the embryonic stage of cell differentiation. A blow is a mechanical force; when it is applied to the womb during the embryonic differentiation of cells it can cause a deformity in the fetus and consequently, the newborn. For example, a mechanical shock transmitted to the limb buds



can later cause the baby to have seven toes on each foot and no elbows, because the limb buds contain in themselves the ideas of toes and elbows which will later differentiate into the actual toes and elbows. Excessive or unwanted application of mechanical forces to the embryo may cause a group of deformities called mutilations. In *Arbor Deformia*, marvels are created by singularities such as the direct intervention of God. The cases of deformities or inversion of internal organs which are not lethal are usually associated with the direct intervention of God and considered marvels. Jean Macé, a seventy-two-year-old soldier, was dissected after his death and found to be a perfect epitome of *situs inversus,* with his heart and spleen being on the right, the liver on the left. Joseph-Guichard Duverney, the French anatomist, declared the case a marvel because the original internal deformity was originally situated in the performed germ in such a way as not to cause death or mutilation.

Occult forces include a wide range of influences and emanations including imagination, electricity, odic and magnetic force, demonic influences, etc. The womb, according to Renaissance teratological models, is the organ which hungers for external forces.[1] Any ambiguous emotion or obscure force directed toward a woman will be absorbed and picked up by the womb. The classic medieval example of the occult influence of imagination upon the embryo is 'a woman looking upon an ape too attentively during her pregnancy and as a result giving birth to a baby with thick black hair covering the entire body and even inside the mouth'. Occult forces can conflict or join with other forces to cause deformities. For this reason, occult forces are mostly involved with fraudulent deformities. For example, electricity as an occult force can combine with a mechanical force and give rise to a fraud. A mother bat warmly breastfeeding its baby on an electricity wire has been electrocuted. The mechanical haptic bond between the mother and the baby has been captured by electricity; and hence, a motherly contact has been deformed to a monstrous fraud (see facing page). Occult forces can also work upon themselves to produce further frauds. A person who has spent a long time in absolute darkness can permeate a spectral image joined to his torso or the back of his head. Such spectral frauds might be in the form of a second head, a shape-shifting and conjoined twin, etc. Such auric or proto-ectoplasmic frauds are usually associated with odic,[2] magnetic or other occult emanations. Occult forces are able to conflict with singularity or alter the will of God into a fraud. A succubus can have sex with a man as he sleeps, turning his dream of being a man to the awakening of a water beetle.

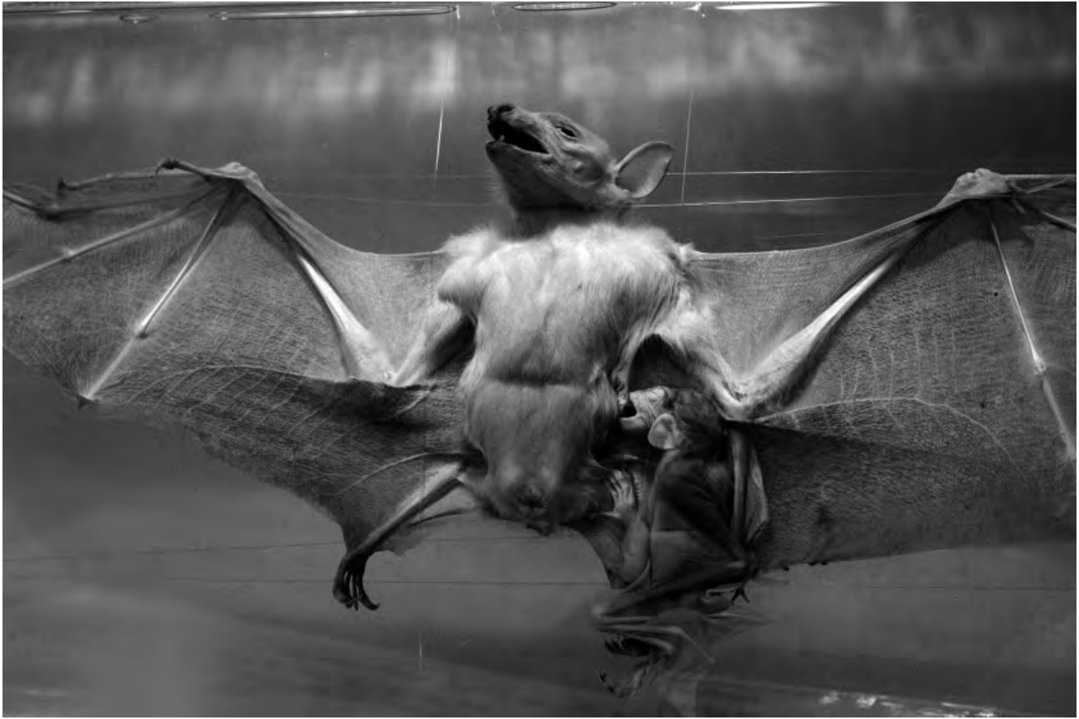
---

[1] According to Renaissance texts, if the female seed does not fruit, it will ferment by its own hunger, rot and turn into vermin which will devour or disfigure the womb (cf. Isabella de Moerloose's account in her autobiography, 1695).

In Far Eastern, especially Chinese, teratology, monsters can come to life through the combination of earthly forces and occult influences. A geopathic force or stress is usually defined in terms of harmful earth rays connected

---

[2] Odic force is a name given in the nineteenth century by Carl von Reichenbach to a hypothetical vital force, a life flux which emanates from vital substances and is similar to electricity and magnetism. Odic force manifests itself most often in the mouth, the hands, the forehead and the occiput and has different laws of distribution than those of electricity: 'Odylo-luminous phenomena of great extent appearing over metal plates (electrified or unisolated) do not adhere to the metallic surface, as the electrical currents do, but flow over it as the aurora borealis does over the earth. Odylic currents do not flow merely from the points but also from the sides of bodies, even of jagged bodies, e.g. large crystals: electricity prefers a point for exit.' (Carl von Reichenbach)



1766

to the earth's electromagnetic fields, fault lines, minerals, underground caves, etc. These forces can combine with occult forces which influence the plane of geo-mechanics and cause particular deformities. A boy at the onset of puberty who walks along and over leylines or other energy lines can be influenced by earthly-occult radiations which might drive the boy mad or increase the rate of bone growth, enlarging the head or putting an end to his overall growth. In Chinese teratology, there have been cases of pregnant women who, after being exposed to a particular location such as a former altar for sacrificing humans or a house with a dark history, have given birth to extremely deformed babies. Since these deformities are caused by more than one obscure force they are categorized as the group of multiple frauds. The last two forces, the hereditary and inter-specific biological forces, make the organic fold of the tree over which non-organic forces grow and blossom. Unnatural conceptions between pigs and men or ants and lions are among inter-specific biological deformities. While deformation by a corrupt seed belongs to the hereditary forces or forces associated with the lineage. *Arbor Deformia* shows the proportion of its branches to its roots, of the inorganic arms to the organic appendages. Monsters, frauds, marvels, mutilations and multiple frauds are the fruits of this proportional relation.

Notes on Contributors and Acknowledgements

KRISTEN ALVANSON
An American artist living and working in the Middle East, Alvanson has been published in John Russell's anthology *Frozen Tears 3* and has previously contributed to **COLLAPSE**. She is currently exploring the threefold of Middle East, Women and Fabric in a project entitled *Cosmic Drapery* and working on a book entitled *Lessons in Schizophrenia*.

JAKE AND DINOS CHAPMAN
The collaborative works of brothers Jake and Dinos Chapman remain among the most consistently radical and invigorating forces in contemporary art. They have exhibited internationally and were recently the subject of a major retrospective at the Tate Liverpool in 2006-7 (See *Bad Art for Bad People*, ed. C. Grunenberg and T. Barson, London: Tate Publishing, 2006).

IAIN HAMILTON GRANT
Senior Lecturer in Philosophy at the University of the West of England. He has written widely on post-Kantian European philosophy and is translator of Lyotard's *Libidinal Economy* and Baudrillard's *Symbolic Exchange and Death* and author of *Philosophies of Nature After Schelling* (London: Continuum, 2006).

GRAHAM HARMAN
Professor of philosophy at the American University in Cairo, Egypt, and currently Visiting Associate Professor at the University of Amsterdam. Author of *Tool-Being* (Chicago: Open Court, 2002), *Guerrilla Metaphysics* (Chicago: Open Court, 2005), *Heidegger Explained* (Chicago: Open Court, 2007), and *Prince of Networks: Bruno Latour and Metaphysics* (forthcoming).

Michel Houellebecq

As well as being the author of several bestselling novels, including *Atomised* (trans. F. Wynne, London: Heinemann, 2000) – filmed by Oscar Roehler in 2006 – and *Platform* (trans. F. Wynne, London: Heinemann, 2002), Michel Houellebecq has published several books of poetry (collected in *Poésies*, Paris: J'ai Lu, 2000) and various essays – notably his 1991 book on H. P. Lovecraft *Against the World, Against Life* (trans. D. Khazeni, San Francisco, CA: Believer Books, 2005). Houellebecq's most recent novel was *The Possibility of an Island* (2005, trans. G. Bowd, London: Weidenfeld & Nicolson, 2007). He now lives and works in Ireland.

Oleg Kulik

The practice of Oleg Kulik, who has been internationally acclaimed as one of the most radical artists working today, encompasses extraordinary live actions, manipulated photography and other media. Much of his past work has been concerned with exploring the subject of animal as human being or animal as a non-anthropomorphous Other. A book documenting Kulik's work since 1993 accompanied his 2001 performance in the UK (*Oleg Kulik: Art Animal*, Birmingham: Ikon Gallery 2001). He is represented by XL Gallery, Moscow (xlgallery@gmail.com).

Thomas Ligotti

Thomas Ligotti has gathered a dedicated cult following and garnered critical acclaim and awards for his fiction, which includes the collections *Teatro Grotesco* (London: Random House, 2008), *Noctuary* (New York: Carroll and Graf, 1994) and *Songs of a Dead Dreamer* (London: Robinson Publishing, 1989). He is currently working on a volume of theoretical writings entitled *The Conspiracy Against the Human Race*.

QUENTIN MEILLASSOUX

A graduate in philosophy from the École Normale Superieur, Quentin Meillassoux wrote his doctoral thesis on *The Divine Inexistence: An Essay on the Virtual God*, and has been teaching philosophy at the ENS since 1997. He is author of *Après la finitude: Essai sur la nécessité de la contingence* (Paris: Seuil 2006; English translation *After Finitude*, trans. R. Brassier, London: Continuum, 2008).

CHINA MIÉVILLE

China Miéville is an author of weird fiction. He has won the Arthur C Clarke Award twice, for his novels *Perdido Street Station* (London: Macmillan, 2000) and *Iron Council* (London: Macmillan, 2004). His other books include a collection of short fiction, *Looking for Jake* (London: Macmillan, 2005), and a book for younger readers, *Un Lun Dun* (London: Macmillan, 2007). His non-fiction includes *Between Equal Rights: A Marxist Theory of International Law* (London: Haymarket, 2005).

REZA NEGARESTANI

Reza Negarestani is a philosopher working in Shiraz, Iran. He is the author of *Cyclonopedia: Complicity with Anonymous Materials* (Melbourne: Re.Press, forthcoming 2008).

BENJAMIN NOYS

Benjamin Noys teaches in the Department of English at the University of Chichester. He is the author of *Georges Bataille: A Critical Introduction* (London/Sterling, VA: Pluto Press, 2000) and *The Culture of Death* (Oxford/NY: Berg, 2005). Currently he is writing a new book, *The Persistence of the Negative*.

RAFANI

The art collective Rafani have exhibited extensively in the Czech Republic and elsewhere since their founding in 2000 by four students from Prague's Academy of Fine Arts. Their constitution states that they 'build on the everyday experience of wide social strata; we analyse it and look for points that go beyond the sphere of the mundane. With a conscious art form we attempt to reflect their interests, dreams, fears, and ambitions. What we express is in harmony with their ideas; we speak the language of bitter truth.'

STEVEN SHEARER

Steven Shearer is an artist who lives and works in Vancouver, Canada. Shearer exhibits internationally, with recent exhibitions including solo presentations at the IKON Gallery, Birmingham, The Power Plant, Contemporary Art Gallery, Toronto, and De Appel, Amsterdam, most recently showing at the New Museum, New York in a two person exhibition entitled *Double Album*.

GEORGE SIEG

George J. Sieg is a doctoral research student at Exeter Centre for the Study of Esotericism, currently writing his PhD thesis on the genesis and development of occult warfare. He is also preparing for publication a monograph on the origins of Zoroastrian dualism and the concept of *Druj*. He continues to pursue further opportunities to explore the liminal boundary between esoteric and academic theory and praxis.

EUGENE THACKER

Eugene Thacker is associate professor of new media at the Georgia Institute of Technology. His publications include *Biomedia* (Minneapolis: U. Minnesota Press, 2004) and *The Global Genome: Biotechnology, Politics and Culture* (Cambridge, Mass.: MIT Press). He has recently published (with Alexander Galloway) *The Exploit: A Theory of Networks* (Minneapolis: U. Minnesota Press, 2008).

KEITH TILFORD
An artist currently working in Seattle, USA, Keith Tilford's blog can be found at http://metastableequilibrium.blogspot.com

JAMES TRAFFORD
James Trafford is a doctoral student at the University of East London, nearing completion of his dissertation in post-Kantian materialism. He is most interested in pursuing the intersection of continental philosophy and philosophy of mind, and in particular, the asymmetry of phenomenal experience and scientific realism.

TODOSCH
Perhaps best known for his attempt to attack the 2000 Hanover Expo with a paramilitary convoy, artist Thorsten Schlopsnies, AKA Todosch, has also exhibited sculpture and graphic work, and has been involved in various musical projects, as well as staging live actions. See http://todosch.felix-werner.net/

COLLAPSE

Philosophical Research and Development

VOLUME IV

CONTRIBUTORS: **Kristen Alvanson, Jake and Dinos Chapman, Iain Hamilton Grant, Graham Harman, Michel Houellebecq, Oleg Kulik, Thomas Ligotti, Quentin Meillassoux, China Miéville, Reza Negarestani, Benjamin Noys, Rafani, Steven Shearer, George Sieg, Eugene Thacker, Keith Tilford, Todosch, James Trafford.**

COLLAPSE IV features a series of investigations by philosophers, writers and artists into 'Concept Horror'. Contributors address the existential, aesthetic, theological and political dimensions of horror, interrogate its peculiar affinity with philosophical thought, and uncover the horrors that may lie in wait for those who pursue rational thought beyond the bounds of the reasonable.

This unique volume continues **COLLAPSE**'s pursuit of indisciplinary miscegenation, the wide-ranging contributions interacting to produce common themes and suggestive connections. In the process a rich and compelling case emerges for the intimate bond between horror and philosophical thought.

forthcoming titles

The Mathematics of Novelty: Badiou's Minimalist Metaphysics
Sam Gillespie

Gillespie tackles the issue of philosophical materialism in Deleuze and Badiou, enquiring after the source and nature of the 'novelty' that both philosophers of multiplicity claim to discover in the objective world. Working with the addition of Lacan's concept of anxiety, the author illuminates the form of the relation Badiou determines between philosophy and its conditions (art, love, science, politics). This leads to the polemical conclusion that, as a transformative project Badiou's philosophy ultimately reclaims the power of the negative from the positivity and pure productiveness of Deleuze's system, thereby freeing thought from the limits set by experience.

The Radical Critique of Liberalism: In Memory of a Vision
Toula Nicolacopoulos

There are many books about liberalism, but no defence of radical critique that treats liberal theory with the depth, breadth and intensity of this work. Rigorously examining Rawls, Waldron, Larmore and Kymlicka, the book demonstrates that an adequate appreciation of the deep structural flaws of liberal theory presupposes the application of a critical philosophical methodology that has the power to reveal the systemic interconnections within and between the varieties of liberal inquiring practices.

Hegel's Jena Philosophy of Nature - 'The Organics'
G.W.F Hegel (translated by Erich D. Freiberger)

Never before translated, this part of Hegel's work represents a significant contribution to both Hegelian scholarship and modern philosophy as a whole. This translation consists of 'the Organics' of 1803/4 and 1805/6 from Hegel's early Jena Philosophy of Nature.

Cyclonopedia: Complicity with Anonymous Materials
Reza Negarestani
The *Cyclonopedia* manuscript remains one of the few books to rigorously and honestly ask what it means to open oneself to a radically non-human life—this is a text that screams, from a living assemblage known as the Middle East, 'I am legion.' *Cyclonopedia* refuses to be called either 'theory' or 'fiction'; a heady mixture of philosophy, the occult, and the tentacular fringes of Iranian culture—call it 'occultural studies' (Eugene Thacker, author of *Biomedia* and *The Global Genome*).

The Charmed Circle of Ideology: A Critical Analysis of the Emergence of Postmarxism
Geoff Boucher
Boucher combines close reading, careful exposition and polemical intent to offer an immanent critique of 'postmarxian' cultural theory. Concentrating his attention on Laclau and Mouffe, Butler and Žižek, Boucher links the relativism exemplified in contemporary theoretical trends to unresolved philosophical problems of modernity. In conclusion, Boucher points to 'intersubjectivity' as an exit from postmarxist theory's charmed circle of ideology.

University of the West of England, Bristol

An opportunity to study in depth the great traditions of Modern European philosophy, along with its most important contemporary tendencies.

MA European Philosophy

The MA European Philosophy, taught by expert staff, offers a uniquely broad postgraduate-level introduction both to the great works of that tradition, and the main tendencies evident in contemporary European Philosophy.

2008-9 modules include:

- The Post-Kantian Tradition (Hegel, Fichte, Schelling)
- Phenomenology (Merleau-Ponty)
- Contemporary French Philosophy (Deleuze, Badiou)
- Heidegger's *Being and Time*
- Kant's *Critique of Pure Reason*

Core Staff:
Iain Hamilton Grant, Havi Carel, John Sellars, Alison Assiter, Sean Watson

UWE
BRISTOL
University of the
West of England

The University of the West of England (UWE) is a modern, growing university in the thriving city of Bristol. The MA in European Philosophy is based at UWE's St Matthias Campus.

pli

The Warwick Journal of Philosophy
Volume 19 (2008)

Sense and Nonsense

'The pendulum of the mind alternates between sense and nonsense, not between right and wrong.'

Carl Jung, *Memories, Dreams, Reflections*

'In order to be able to draw a limit to thought, we should have to find both sides of the limit thinkable (i.e. we should have to be able to think what cannot be thought). It will therefore only be in language that the limit can be drawn, and what lies on the other side of the limit will simply be nonsense.'

Ludwig Wittgenstein, *Tractatus Logico-Philosphicus*

'Philosophy must be ontology, it cannot be anything else; but there is no ontology of essence, there is only an ontology of sense.'

Gilles Deleuze, *Review of Logic and Existence*

Pli is a journal of philosophy edited and produced by members of the Graduate School of the Department of Philosophy at the University of Warwick. *Pli* has no specific set of philosophical concerns but previous issues have tended to focus upon European philosophical traditions, reflecting the interests of the graduate community at Warwick. In particular, Pli has published translations of works otherwise unavailable in English by philosophers including Éric Alliez, Gilles Deleuze, Jacques Derrida, Michel Foucault, François Laruelle, Jean-François Lyotard, Jean-Luc Nancy, and Friedrich Nietzsche.

Volume 19 is a collection of papers dealing with the issue of sense and nonsense, in particular in relation to notions such as scepticism, immanence, and expression in philosophy, in the work of such thinkers as Wittgenstein and Deleuze. It also contains various articles on or by writers such as Badiou, Lacan, and Maimon, and a number of reviews of recent publications in continental philosophy.

VOLUME IV

CONTRIBUTORS: **Kristen Alvanson, Jake and Dinos Chapman, Iain Hamilton Grant, Graham Harman, Michel Houellebecq, Oleg Kulik, Thomas Ligotti, Quentin Meillassoux, China Miéville, Reza Negarestani, Benjamin Noys, Rafani, Steven Shearer, George Sieg, Eugene Thacker, Keith Tilford, Todosch, James Trafford.**

COLLAPSE IV features a series of investigations by philosophers, writers and artists into 'Concept Horror'. Contributors address the existential, aesthetic, theological and political dimensions of horror, interrogate its peculiar affinity with philosophical thought, and uncover the horrors that may lie in wait for those who pursue rational thought beyond the bounds of the reasonable.

This unique volume continues **COLLAPSE**'s pursuit of indisciplinary miscegenation, the wide-ranging contributions interacting to produce common themes and suggestive connections. In the process a rich and compelling case emerges for the intimate bond between horror and philosophical thought.

Editorial Introduction

Damian Veal[1]

> [T]hough the medieval world was [...] immense, relatively to man and his planet, it was nevertheless definitely limited and fenced about. It was therefore essentially picturable; the perspectives which it presented, however great, were not wholly baffling to the imagination.[2]

> Copernicanism tore asunder the fit between the world and man's organs: the congruence between reality and visibility [...] The breakdown of the postulate of visibility – taken in its widest sense – is brought to a point by a kind of reversal: The visible world is not only a tiny section of physical reality, but it is also, qualitatively, the mere foreground of this reality, its insignificant surface, on which the outcome of processes and forces is only symptomatically displayed. Visibility itself is an eccentric configuration, the accidental convergence of heterogeneous sequences of physical events.[3]

Almost five hundred years after Nicolaus Copernicus' death, the notion of 'Copernicanism' continues to be a compelling one for science, philosophy and the popular imagination alike. However 'Copernicanism' stands for a legacy which is still contested, as the multiple perspectives collected in this, the fifth volume of **Collapse,** reveal; and as was amply demonstrated by some recent events.

---

[1] I would like to extend my thanks to Robin Mackay for his comments and contributions to this introduction, in particular the sections on the work of Nigel Cooke and Keith Tyson. Thanks also to Ray Brassier for his critical comments.

While in the penultimate stages of editing this volume in late November 2008, it was widely reported in the world's media that researchers in Poland had identified the remains of Nicolaus Copernicus by comparing DNA from a skeleton with that of a hair retrieved from one of the sixteenth-century astronomer's books. The findings, it was reported, were 'the culmination of four years of investigation and centuries of speculation about the final resting place of the man who challenged the Bible and medieval teachings of the church'.[4] The Catholic bishop who had instigated the archaeological search, however, knowing full well that Copernicus had never harboured any such heretical intentions, used the opportunity to point out that Copernicus had in fact been 'a deeply religious clergyman and cathedral canon who dedicated his main work to the Pope and presented his faith clearly'.[5]

The bishop of course neglected to mention the fact that it had taken no less than four and a half centuries and a succession of forty-four popes before one of latter took it upon himself to officially admit that Copernicus may actually have had a point.[6] Instead, he proposed that the discovery should lead humanity to reflect that centuries of conflict between scripture and empirical science had really

Digital reconstruction of the head of Nicolaus Copernicus, on the basis of remains identified by Polish scientists in late 2008 as being those of the sixteenth-century astronomer.

only been a lot of fuss about nothing – a 'great misunderstanding' brought about by the fact that people had 'made the mistake of absolutising one philosophical vision without reflecting on new insights and discoveries'.[7] The implication, of course, was that no 'philosophical vision' ought to be so absolutised, and that we must finally come to understand that there is really no substantive conflict between science and Church doctrine at all – a conciliatory sentiment fittingly symbolised by the fact that Copernicus' remains, identified by means of advances made in late twentieth-century genetics and computer technology, are now set to be reinterred during the celebrations planned for Frombork Cathedral's 750th anniversary in 2010.[8] In thus ceremoniously returning Copernicus' remains to the consecrated grounds of this ancient place of worship, perhaps it is hoped that 'Copernicanism' itself, and the unholy forces it unleashed, might finally be buried as well.

Remarkably enough, this was not the only news report involving Copernicanism and the Catholic Church to appear during the final stages of the preparation of this volume. Just five days after the story about the identification of Copernicus' remains, *The Times* put out the headline 'Vatican Seeks to Rehabilitate Galileo Galilei', while *The Boston Pilot* ran with 'Vatican Official Says Galileo Was a Man of Faith'.[9] The occasion this time was the appearance of an article entitled 'Thank you, Galileo' on the front page of the Vatican's official newspaper, announcing a series of events planned by the Vatican for 2009 to coincide with the celebrations surrounding the 400th anniversary of Galileo's first observations with a telescope. Earlier in 2008, Pope Benedict XVI had been obliged to cancel a planned visit to Rome's principal university due to vehement protests from academics and students who had accused him of hostility towards science, citing his alleged endorsement of the Inquisition's condemnation of Galileo. (In a speech in 1990, the then Cardinal Ratzinger had cited the philosopher of science turned anarchist-cum-Dadaist Paul Feyerabend's comment that the verdict against Galileo had been 'rational and just'.)[10] Given the negative press following from this incident, it seems that the Vatican had thought it expedient to publicly 'reclaim' Galileo for the Church, very much in the way that the Polish bishop had used the identification of Copernicus' remains as an opportunity to posthumously bring him back within the fold.

---

[7] 'Bishop', *Total Catholic*, op. cit.

[8] Ibid.

[9] *Times Online*, 26 November, 2008; *The Boston Pilot*, 5 December 2008.

Citing Pope Benedict XVI's statement that Galileo had been 'a man of faith who saw nature as a Book written by God', the author of the Vatican's newspaper article reiterated the sentiment of the Polish bishop, insisting that the Galileo celebrations should 'encourage people to consider seriously the relationship between faith and science; lead scientists to recognize the role faith played in Galileo's life; and lead theologians to recognize the contributions Galileo made to the church's attitude toward science'.[11] Having announced in November that a statue of Galileo was to be erected in the Vatican gardens, the Pope then used the onset of the Winter solstice on the 21st of December as an opportunity to remark upon not only the coincidence of Christmas with the solstice and 'the function of astronomy in marking out the rhythm of prayer', but to once again praise Galileo and his telescope for the way in which they had stimulated appreciation of God's work: 'If the heavens', said the Pope, 'according to the beautiful words of the psalmist, "proclaim the glory of God" (Psalm 19 [18]: 2), then the laws of nature, which over the course of the centuries many men and women of science have helped us to understand better, are also a great stimulus to contemplate with gratitude the works of the Lord.'[12] One can only surmise what the official Vatican line will be with respect to the imminent celebrations for the 200th anniversary of Darwin's birth and the 150th anniversary of *The Origin of Species* in 2009. Will it be claimed that Darwin too had been a 'man of faith', and that evolution likewise bears witness to the glory of the Lord's Creation?[13]

---

[10] See, e.g., 'Pope pulls out of visit to Rome university after outrage at his views on Galileo and science', *The Guardian*, 16 January, 2008. The passage cited by Ratzinger is taken from Paul Feyerabend, *Wider den Methodenzwang*, 2nd ed. (Frankfurt am Main: Suhrkamp, 1983), 206. For helpful scholarly (rather than journalistic) treatment of the Feyerabend passage, and Ratzinger's citation of it, see Ernan McMullin, 'Quoting Feyerabend on Galileo', *Irish Theological Quarterly* 73, 2008: 164-73.

[11] 'Vatican Official Says Galileo Was a Man of Faith', *The Boston Pilot*, op. cit.

Of course, that Nicolaus Copernicus and Galileo Galilei were 'men of faith' is uncontroversial. Indeed, given that the Pope's comments were made in connection with the quatercentenary of Galileo's first use of the telescope, he might have done well to point out that, in his 1610 *Sidereus nuncius* (i.e., the book in which his first telescopic observations were reported), Galileo had enthusiastically declared that he had devised the telescope 'after being illuminated by divine grace.'[14] Moreover, as Hans Blumenberg and Karsten Harries have documented, the advent of the telescope in the seventeenth century was seized upon by the likes of Francis Bacon and Joseph Glanvill as an invention which promised a technological restitution of the perfect clarity of vision which humanity had supposedly lost with Adam's fall. Adam, surmised Glanvill,

[12] See the news headlines for 21 December 2008: 'Pope Praises Galileo's Astronomy' (*BBC News*), 'From Heretic to Hero: Pope Pays Tribute to Galileo' (*ABC Online*), 'Pope Benedict XVI Celebrates Galileo's Astronomy' (*The Telegraph*).

[13] Given the fact that in April 2007 Pope Benedict gently 'corrected' Pope John Paul II's 1996 statement that evolution was 'more than a hypothesis', stating that while his predecessor 'had his reasons for saying this, it is also true that the theory of evolution is not a scientifically proven theory', this seems rather less than likely. See 'Pope Stokes Debate on Darwin and Evolution', *Times Online*, April 12, 2007.

> needed no Spectacles. The acuteness of his natural Opticks (if conjecture may have credit) shew'd much of the Coelestial magnificence and bravery without a Galilaeo's tube: And 'tis most probable that his naked eyes could reach near as much of the upper world, as we with all the advantages of art. It may be 'twas as absurd even in the judgement of his senses, that the Sun and Stars should be so very much less than this Globe, as the contrary seems in ours; and 'tis not unlikely that he held as clear a perception of the earth's motion, as we think we have of its quiescence.[15]

Glanvill's book was published just fifteen years before Olaf Römer's discovery of the finite speed of light in 1676 – a discovery scarcely less momentous than that of the

[14] 'All these facts were discovered by me not many days ago with the aid of a spyglass which I devised, after being illuminated by divine grace.' Galileo Galilei, *The Starry Messenger*, in *Discoveries and Opinions of Galileo*, trans. S. Drake (New York: Anchor Books, 1957), 28.

[15] Joseph Glanvill, *The Vanity of Dogmatizing* (1661), cited in Harries, *Infinity and Perspective*, op. cit., 106. On seventeenth-century attitudes toward both the telescope and microscope, see also Catherine Wilson, *The Invisible World: Early Modern philosophy and the Invention of the Microscope* (Princeton: Princeton University Press, 1995).

Copernican revolution itself, and which was later adverted to in Mark Twain's posthumously published *Letters from the Earth*, wherein Satan, in one of the most cruelly cynical tirades against human vanity ever written, points out that at the beginning of Creation not even a single star would have been visible in the sky over the biblical Paradise, and that even at the end of a thousand years there still would not have been enough to 'make a show'.[16] Yet as Blumenberg suggests, Bacon's idea of making the recovery of Paradise into the goal of historical progress through science, and Glanvill's expectation that the telescope might ultimately enable man to recoup his prelapsarian intuitive prowess, should be understood less as the secularisation of an originally religious idea and more as a way of safeguarding an anthropology in which man and cosmos are seen as 'coordinated in such a way that no essential incongruence can be assumed between man's organic equipment and the constituents of reality'.[17] No wonder, then, that Bacon, the anti-Copernican, expressed such alarm at the idea of the finite speed of light:

> It seemed to him shocking (*dubitatio plane monstrosa*) that in looking at the starry heavens we could catch sight only of the past, something that might have long since ceased to be real – that the *tempus visum* and *tempus verum* [apparent time and true time] could split apart arbitrarily [...] that the presentation of the starry heavens, which man had so long related to himself as the one who was called to observe it, could be a mere appearance

---

[16] Mark Twain, *Letters from the Earth* (New York: Harper & Row, 1962), 15. Twain wrote the book in 1909; it was not published until 1962.

[17] *The Genesis of the Copernican World*, op. cit., 629, cf. 635 and Part VI, Chapter 1: 'How Horizons of Visibility Are Conditioned by Views of Man', 622-642 *passim*.

> also in that it was not the homogeneous total reality that it presents itself as in intuition, but instead was nothing but an accidental section through the many layered depths of huge temporal differences.[18]

According to Blumenberg, the epochal significance not only of Copernicanism but also of what we might call 'Römerianism', is thus not so much that it entailed 'man's removal from the centre',[19] but rather that it rendered obsolete once and for all the medieval equation of reality and visibility,[20] thus revealing a seemingly unbridgeable chasm between our biologically-inherited perceptual faculties and the sheer scale and complexity of the universe. While Copernicus himself could still employ as a premise in arguing for the truth (rather than mere empirical adequacy) of his theory the idea that the universe had been created 'on our behalf' or 'for our sake' (*propter nos*) by a supremely good and orderly Creator,[21] such a teleological, anthropocentric conception of the universe became increasingly difficult to maintain in the wake of Römer's demonstration of the finite speed of light – that is, at least, for those who were cognizant of its implications. How, after all, could one continue to regard man as the privileged *contemplator caeli*, as the specially appointed witness of the wonders of creation, when the time required for the light to reach him from unknown star systems was longer than the entire duration of the earth?

---

[18] Ibid., 542.

[19] As scores of historians have not failed to point out, this standard narrative is inherently implausible inasmuch as the medieval conception of the cosmos was less anthropocentric than *diabolocentric*, the earth being regarded as 'the filth and mire of the world, the worst, lowest, most lifeless part of the universe, the bottom story of the house' (Montaigne as quoted by Arthur Lovejoy, *The Great Chain of Being*, op. cit., 102) and the actual centre of the universe being identified with hell. As late as 1640 an English supporter of Copernicanism recognised one of the strongest current arguments against heliocentrism as proceeding from 'the vileness of our earth, because it consists of a more sordid and base matter than any other part of the world; and therefore must be situated in the centre, which is the worst place' (ibid.). Galileo himself, in the work already cited, took himself to be furnishing a refutation of 'those who argue that the earth must be excluded from the dancing swirl of stars for the specific reason that it is devoid of motion and of light. We shall prove the earth to be a wandering body surpassing the moon in splendor, and not the sink of all dull refuse of the universe; this we shall support by an infinitude of arguments drawn from nature' (*The Starry Messenger*, op. cit., 43). Thus, from the perspective of pre-modern cosmology and theology, Copernicanism, far from entailing the *demotion* of the earth and of man, actually amounted to their *exaltation*. For a brief but helpful survey of the evidence, see Dennis Danielson, 'The Great Copernican Cliché', *American Journal of Physics* 69 (1), 2001: 1029-35.

[20] This is what Blumenberg calls 'the postulate of visibility' in our epigraph.

In this regard, the fact that UNESCO elected 2009 as the International Year of Astronomy on the grounds that it is the 400th anniversary of Galileo's first telescopic observations speaks volumes with regard to what Blumenberg called 'man's optical neediness',[22] and is symptomatic of the extent to which we are still in thrall to what Popper called 'the Baconian myth' – that is, the idea 'that all science starts from observation and then slowly and cautiously proceeds to theories'.[23] Galileo's telescopic observations – observations which first made visible the moons of Jupiter, the ring of Saturn, the phases of Venus, and the craters and mountains of the moon – were certainly of great scientific and historical significance. However, 1609 witnessed another breakthrough in astronomy which was even more portentous, yet which has not even so much as been mentioned in relation to the forthcoming quatercentenary celebrations: namely, the publication of Kepler's *Astronomia nova*. Not only did this book lay the very foundations of modern astronomy and physics, but it did so on the basis of precisely that kind of resolute refusal to be taken in by the self-evidences of sensible intuition which Galileo professed to so admire in Copernicus.[24] Indeed, in comparison with Kepler's break with tradition in abandoning the 'Platonic' requirement that all celestial orbits be circular, Galileo's telescopic observation of the Jupiter system 'seems extremely conventional [...] an attempted *coup de main* of intuition, by means of the telescope, to carry the day for Copernicanism', with Galileo's medieval faith in what he called 'the certainly of sense evidence'[25] blinding him to the momentous achievements of Kepler.

---

[21] In the Preface to *De Revolutionibus*, Copernicus states that the reason he set out to see if the assumption of a moving Earth would provide better explanations of celestial phenomena was that he had been 'annoyed with the philosophers, who while in other respects had made a very careful scrutiny of the least details of the world, had discovered no sure scheme for the movements of the machinery of the world, which was built for us by the Best and Most Orderly Workman of all' (*On the Revolution of Heavenly Spheres*, in [ed.] Stephen Hawking, *Standing on the Shoulders of Giants: The Great Works of Physics and Astronomy*, London & New York: Penguin Books, 2002, 10). The seeming paradox of this unequivocal statement of teleological anthropocentrism ('built for us' or 'on our behalf') as the motivating reason for the Copernican revolution is examined at length in Blumenberg's *The Genesis of the Copernican World*, op. cit.

[22] Blumenberg, *The Genesis of the Copernican World*, op. cit., 632.

---

[23] Karl Popper, *Conjectures and Refutations* (London and New York: Routledge, 1963), 185.

[24] In his *Dialogue Concerning the Two Chief World Systems*, in response to Sagredo's expression of surprise that Pythagoreanism 'has found so few followers in the course of centuries' and that 'even Copernicus is not having any better luck with it in these latter days', Galileo-Salviato replies: 'No, Sagredo, my surprise is very different from yours. You wonder that there are so few followers of the Pythagorean opinion, whereas I am astonished that there have been any up to this day who have embraced and followed it. Nor can I ever sufficiently admire the outstanding acumen of those who have taken hold of this opinion and accepted it as true; they have through sheer force of intellect done such violence to their own senses as to prefer what reason told them over that which sensible experience plainly showed them to the contrary.' (This quotation is from the Third Day of Galileo's *Dialogue Concerning the Two Chief World Systems* [1632]; the English translation of the full text by Stillman Drake is available online at http://www.law.umkc.edu/faculty/projects/ftrials/galileo/dialogue.html.)

The idea that direct, first-person observation provides not only the ultimate *source* of knowledge but also its *fulfilment*, that reason and theory are only ever an anticipation of intuition (the latter being regarded as the very essence of a fully realised relation to reality), is one that has very deep roots in Western philosophy. Indeed, it is one which governs the traditional historiography of science whenever the demise of the Aristotelian philosophy of nature is attributed to the latter's allegedly speculative, non-empirical stance, being superseded by a thoroughly empirical approach to science. But on the contrary, as Blumenberg suggests, the downfall of Aristotelian physics is better described by the lapidary sentence of Heinrich Scholz: 'It perished as a result of its positivism'.[26] It is well known that the Aristotelian physics is in fact very close to the commonsense 'folk physics' of everyday experience, and 'is familiar to us in a way that Galileo's and Newton's never can be'.[27] What was needed to overcome the Aristotelian philosophy of nature was not simply more experience, or greater attention to the way things appear, but rather a different *kind* of experience, 'an experience which was already directed toward specific premises – selected and arranged in accordance with them – and placed under definite conditions: in other words, *experimental* experience':

[27] Lewis Wolpert, *The Unnatural Nature of Science* (Cambridge, Mass.: Harvard University Press, 1991), 3.

> This type of experience never presents itself immediately, and is not exhausted in intuitive givenness. It confirms or disproves assumptions in regard to a definite and, at least in principle, measurable aspect of a total phenomenon. Experience that is controlled – not to say prepared or dissected – in this way cannot stand at the beginning of radical theoretical change. Instead, what stands at this beginning is a distancing from the immediacy of the life-world.[28]

It was precisely this transformation of the notion of experience that Kant recognised as the revolution which placed the study of nature 'on the secure path of a science', and upon which he modelled his own 'transcendental' revolution in metaphysics:

> When Galileo caused balls, the weights of which he had himself previously determined, to roll down an inclined plane; when Torricelli made the air carry a weight which he had calculated beforehand to be equal to that of a definite volume of water; or in more recent times, when Stahl changed metal into lime, and lime back into metal, by withdrawing something and then restoring it, a light broke upon all students of nature. They learned that reason has insight only into that which it produces after a plan of its own, and that it must not allow itself to be kept, as it were, in nature's leading-strings, but must itself show the way with principles of judgement based upon fixed laws, constraining nature to give answer to questions of reason's own determining. Accidental observations, made in obedience to no previously thought-out plan, can never be made to yield a necessary law, which alone reason is concerned to discover.[29]

[28] Blumenberg, *The Genesis of the Copernican World*, op. cit., 394.

[29] Immanuel Kant, *Critique of Pure Reason*, trans. N. K. Smith (London: Macmillan, 1929), Bxii-xiii.

While one might agree with Popper that Kant's statement that '[o]ur intellect does not draw its laws from nature [...] but imposes them upon nature' must be modified as 'but tries – with varying degrees of success – to impose upon nature laws which it freely invents',[30] Kant's statement is significant for its recognition of the way in which the history of science refutes the Baconian myth that all science starts from pure observation. Once modified in the way suggested, one ends up with Popper's notion of science as the forwarding of risky conjectures and bold speculations which, while they may be 'in striking contrast to the everyday world of common experience', are 'yet able to explain some aspects of this world of common experience'.[31] This is a tradition to be valued for 'its ability to free our minds from old beliefs, old prejudices, and old certainties, and to offer us in their stead new conjectures and daring hypotheses'.[32] Such speculatively audacious attempts to '*explain the known by the unknown*' have immeasurably extended the realm of the known, adding to the facts of our everyday world 'the invisible air, the antipodes, the circulation of the blood, the worlds of the telescope and the microscope, of electricity, and of tracer atoms showing us in detail the movements of matter within living bodies'.[33]

It is precisely this willingness to question and even radically overturn the commonsense or intuitive image of the world that **Carlo Rovelli** identifies as the essence of the scientific enterprise in the first essay of the present volume, 'Anaximander's Legacy'. Drawing upon both his extensive historical erudition and his first-hand experience of research at the cutting-edge of contemporary theoretical physics, Rovelli meditates on the question 'What is Scientific Thinking?' and takes us on a tour through some of the most profound conceptual revolutions of the history of science. As one of the founders of loop quantum gravity – today widely recognized as the leading rival to string theory in the quest to unify general relativity and quantum mechanics – there is scarcely anyone alive today in a better position to reflect upon the counterintuitive nature of modern science than Rovelli. Providing as it does a stimulating overview of the way in which science continually 'redraws the image of the world' based on its perpetual 'rebellion against what appears obvious', Rovelli's essay is a fitting introduction to the 'Copernican imperative' to which this volume of **COLLAPSE** is devoted.

[30] Popper, *Conjectures and Refutation*, op. cit., 259; emphasis added.

[31] Ibid., 137.

[32] Ibid., 136-7.

[33] Ibid.

By all accounts, Anaximander's studies were vast in scope, comprising a cosmogony, a history of the earth and the heavenly bodies, a proto-Darwinian account of the development of living organisms and the origin of species, studies in astronomy, meteorology and biology, a geography, as well as the first attempt to describe the structure of the universe in mathematical terms. But it was Anaximander's conjecture that the earth 'is held up by nothing, but remains stationary owing to the fact that it is equally distance from all other things'[34] that Rovelli singles out as the 'gigantic leap in our understanding of the world' which set in motion the naturalistic inquiry that ultimately evolved into modern science. Popper described this hypothesis as 'one of the boldest, most revolutionary, and most portentous ideas in the whole history of human thought',[35] and it is not hard to see why. While every account of which we have a record, including that of Anaximander's teacher Thales, pictures the earth as resting upon some support or other, Anaximander boldly conjectures, against the evidence of sense experience, that the earth is suspended in mid-space. Faced with the mutually contradictory commonsense beliefs that everything moves downwards, and yet that the earth is at rest, Anaximander in effect accepts the latter of these conflicting judgments and rejects the application of the former to the earth, and he does so on the basis of considerations of symmetry and geometrical structure. In short, Anaximander's ingenious answer to the conflicting judgements of common sense amounts to the first application of the Principle of Sufficient Reason of which we have any trace the history of thought: The earth does not fall, conjectures Anaximander, because has no *reason* to move in one direction rather than other. As Rovelli suggests, Anaximander's willingness to reject observation-based judgements in favour of mathematical and logical considerations in constructing his theory amounts to the invention of a completely new grammar for understanding the spatial structure of the universe, one in which the idea of *absolute direction* is abolished. By 'subverting the meaning of "up" and "down", which had provided the most intuitive and elementary way of organizing space and reality for countless generations of humans hitherto', Anaximander 'inaugurates the very process of *rethinking the*

image of the world – the path of investigation of the world which is based on the rebellion against what is obvious' that is characteristic of the scientific enterprise.

How did Anaximander arrive at this remarkable theory? 'Certainly not', writes Popper, 'by observation'[36] but rather by critical engagement with his predecessor Thales – a type of critical engagement which, as Rovelli also suggests, seems to have been invented by the Ionian school. Thales founded a new school in which there was a new relation between master and pupil, one in which the former tolerated, perhaps even encouraged, criticism, one generation after another. It would be difficult to exaggerate the momentousness of this innovation in the history of human thought, representing as it does a break with dogmatic tradition and an admittance of a plurality of competing doctrines which all try to approach the truth by means of critical discussion. As Popper points out, this leads almost by necessity to the realization 'that our attempts to see and to find the truth are not final, but open to improvement; that our knowledge, our doctrine, is conjectural; that it consists of guesses, of hypotheses, rather than final and certain truths; and that criticism and critical discussion are our only means of getting nearer to the truth'.[37] This is a sentiment also strongly endorsed by Rovelli, according to whom it is the Ionian school's 'realization that we can have *valuable* knowledge, but at the same time that this knowledge can be partially wrong' that 'opens up the path for the immense development of subsequent speculation, which is the basis of Greek philosophy and modern science'.

[36] Ibid., 187.

[37] Ibid., 203.

According to Rovelli, today we are 'in the midst of a reconceptualization of our world which is likely to prove every bit as far-reaching as those of Anaximander and Copernicus'. The revolutions of twentieth-century physics, if properly digested, entail 'a change of image of the world far more dramatic than that of Copernicus, and also a change of image of ourselves far more far-reaching than Darwin'.[38] Perhaps most dramatically, Rovelli predicts that we will discover that space and time do not exist at the most fundamental level, that they are in effect a reflection of our ignorance, 'convenient macroscopic approximations, flimsy but illusory and insufficient screens that our mind uses to organize reality'.[39] Moreover, he predicts that we will have to give up the notion that there are 'things' altogether, in favour of a way of thinking about nature that 'refers only to interactions between systems and not to states or changes of individual systems'[40] – an idea also ultimately prepared for by Anaximander's 'gigantic leap', and one which is has a strong affinity with those defended by Julian Barbour, James Ladyman and Gabriel Catren, also in this volume.

[40] Ibid. For detailed treatment of these ideas see for example Carlo Rovelli, *Quantum Gravity* (Oxford: Clarendon Press, 2003); Carlo Rovelli, 'Halfway Through the Woods: Contemporary Research on Space and Time' in J. Earman & J. Norton (eds), *The Cosmos of Science* (Pittsburgh: University of Pittsburgh Press, 1997), 180-223; and 'Quantum Spacetime: What do we know?' in C. Callender and N. Huggett (eds), *Physics Meets Philosophy at the Planck Scale* (Cambridge: Cambridge University Press, 2001), 101-22.

The question Rovelli raises towards the end of his paper – namely, '*Is it possible to think a world without time?*' – is one that has preoccupied theoretical physicist and historian of physics **Julian Barbour** for the best part of five decades. Like the great philosopher-physicists of a century ago such as Ernst Mach, Henri Poincaré and Pierre Duhem, Barbour is not only a physicist but also an eminent historian of science, and it is clear that the breakthroughs he has been able to make in rethinking the foundations of physics are owed in no small part to his considerable historical and epistemological erudition. Having sacrificed a promising career in academia in order to devote himself to exploring his interest in dynamics unencumbered by the 'publish-or-perish syndrome', Barbour set himself the task of a fundamental rethinking of two basic questions that he felt had seldom been seriously asked, let alone satisfactorily answered: 'What is time?', and 'What is motion?' These are precisely the two questions that Leibniz and Mach had raised in their critique of Newton's absolute concepts, but had not answered definitively, and Barbour's entire adult life has been devoted to resolving them. In our interview we discuss with him the way in which his early reading of Mach provided a crucial stimulus to his life's work, ultimately leading him to the most counterintuitive conclusion imaginable: namely, that time *does not exist*. This is of course not a thesis which anyone is likely to take on trust, and in our interview Barbour not only recounts the motivations and influences that led him to embrace it, but also responds to some of the inevitable criticisms that have been voiced in connection with it. Of all the commonsense-defying ideas to be encountered in this volume, Barbour's are surely the most difficult to intuitively digest; and yet, as the reader will discover, they are also ideas to which those working in the most advanced areas of contemporary quantum gravity research, whether it be string theory or loop quantum gravity, are increasingly being drawn.

The problem of the relationship between a mathematicized reality and a human intuition which persists in asking 'how to make sense of this?' is also explored, visually and conceptually, in a unique collaboration between artist **Conrad Shawcross** and philosopher **Robin Mackay** in 'Shadows of Copernicanism'. As Mackay suggests, Shawcross's remarkable 2006 work *Binary Star* provides a potent visual challenge to the heliotropic tendency of the philosophical imaginary, an imaginary in which the sun has always stood as the metaphor for a singular *lumen naturale*, a unique source of enlightenment. For Mackay, *Binary Star* raises questions regarding the philosophical tradition's metaphorical anchorage of thought to apparently fixed and permanent characteristics of the physical world. If Rovelli suggests that the search for 'a fixed point on which to rest is [...] naïve, useless, and counterproductive for the development of science'[41] and Barbour's theory demands that we 'learn how to find our bearings when the solid reassuring framework of the Earth is not there',[42] Mackay suggests that the challenge of philosophical thought today amounts to coming to terms with a scientific worldview 'which disabuses us of every illusion of fixity and permanence'. In this regard, Shawcross's *Binary Star* demonstrates how the 'Copernican cliché' of a 'reversal of perspective between two heavenly bodies' remains tied to 'terrestrial' tropes of thought. If Tycho Brahe's destruction of the crystal spheres prompted Kepler to remark (as quoted by Barbour in our interview) that '[f]rom now on, the planets must find their way through the void like birds through the air' – a remarkably prescient comment in view of the recent discovery of enormous numbers of planet-sized bodies roaming freely in the void between the stars[43] – the physical picture of the world furnished by general relativity is one in which localisation with respect to a background spacetime, or to any fixed external reference system, has no meaning. Mackay suggests that art, given to the image and what is humanly intuitable, insistently inhabits the terrain of this fractured ground, of the gap opened up between mathematical models freed from the contingencies of human visibility and the efforts of intuition and the imagination to make sense of them; and that Shawcross's works mimic the efforts which philosophy must make to incorporate mathematical-scientific models of reality into the grain of language without ceding the latter entirely to mathematical abstraction. Thus the most profound content of the work, suggests Mackay, lies in a vacillation between object and model that indexes its necessary 'failure'.

---

[41] 'Quantum Spacetime: What do we know?', op. cit., 121.

[42] *The End of Time*, op. cit., 71.

The idea that there exists an intimate correlation between reality and visibility, or between the actual and the intuitable, is not one which was left behind with the Middle Ages. Rather, it is one which remains deeply rooted in the human psyche. Not only for the first-person perspective of common sense, for which degrees of phenomenal availability are experienced as degrees of 'realness',[44] but even for significant numbers of contemporary philosophers, 'reality' and 'manifestation' are treated as highly correlative concepts, often even being employed interchangeably. While traditional empiricist and positivist philosophies took the limits of the real to coincide with the boundaries of the (humanly) observable, many self-styled 'critical' philosophers – philosophers, that is, who typically pride themselves upon their overcoming of the 'naïveté' of positivism – continue to persist in the opinion that phenomenology is ontology enough. While earlier philosophers, beginning with Kant, based their critical inquiries upon an extensive familiarity with the best scientific knowledge of their times, many contemporary philosophers, perhaps daunted by the vast and highly-specialised edifice of contemporary science, seem to believe that they can afford to forego the difficult task of acquainting themselves with the methods and results of the sciences altogether.

Cheongho, 'Secure Identification of Free-floating Planets', *The Astrophysical Journal* 644 (2), 2006: 1232-6.

However, as **JAMES LADYMAN** makes clear in our interview 'Who's Afraid of Scientism?', it is not only philosophers working in the Continental tradition who are guilty of such negligence. According to Ladyman and Don Ross in their recent book *Every Thing Must Go: Metaphysics Naturalized*,[45] many of the standard debates in contemporary analytic metaphysics – debates concerning, for example, causation, identity, part-whole relations, and the nature of time – typically involve little more actual science than was available to the early modern philosophers, or even the pre-Socratics.[46] In this regard, what today passes for metaphysics, whether in the Continental or analytic tradition, amounts to a continuation of what Ladyman and Ross call 'the metaphysics of domestication', a tradition 'which aims at domesticating scientific discoveries so as to render them compatible with intuitive or "folk" pictures of structural composition and causation'.[47] While such efforts at domestication are typically defended on the grounds that they provide *understanding* (read: 'rendering more familiar'), in contrast to science itself, which allegedly allows only for *explanation*, Ladyman and Ross argue that such metaphysics cannot be defended 'on the grounds that psychological repose and cultural familiarity are values that might be defended against the objective truth'.[48] However much 'the objective truth' might always be open to revision and correction, such refinement and extension of our knowledge is itself a process which is *internal* to the ongoing project of science itself, and not something that might be achieved by adopting an imaginary stance of philosophical anteriority floating entirely free of the sciences.

[45] James Ladyman and Don Ross with David Spurrett and John Collier, *Every Thing Must Go: Metaphysics Naturalized* (Oxford: Oxford University Press, 2007).

In our interview, Ladyman expresses his exasperation with philosophers unable or unwilling to abandon the constraints of intuition and the manifest image, and who stubbornly insist upon pursuing metaphysics as if modern science had never happened. While many philosophers habitually decry any philosophical position that goes beyond a vague science-friendliness as 'scientistic', Ladyman argues forcefully for a radically naturalistic metaphysics based upon what he and Ross have provocatively called 'the scientistic stance'. As well as explaining why he believes it is incumbent upon philosophers to free themselves from the parochial conceptual prejudices devolving from an uncritical embrace of categories rooted in the manifest image, Ladyman also challenges the all too popular *doxa* that would align science with ideological conservatism. While some philosophers may still dream of 'some kind of new age spirituality that will re-enchant nature, de-alienate us and inaugurate some kind of postmodern arcadia', Ladyman argues that 'the actual alternatives to science are the ideologies of bigotry and superstition'.

---

[46] Ibid., 20.

[47] Ibid., 1 and Chapter One *passim.*

[48] Ibid., 4.

As one of the leading voices in current debates in the philosophy of science, Ladyman has developed, along with Steven French, a distinctive brand of scientific realism he calls 'ontic structural realism', a position that would synthesize the virtues of empiricism and realism by denying the ontological priority of individual objects and properties in favour of the primacy of relational structures. While structural realism in the philosophy of science goes back at least as far as Henri Poincaré a century ago, Ladyman's position is distinctive inasmuch as it construes structural realism as a metaphysical rather than as a merely epistemological thesis. In other words, while Poincaré held that all that we can *know* are the structures of or relations holding between inscrutable objects in themselves, Ladyman argues that these structures are *all that there is*, thus closing the gap between epistemology and metaphysics entailed by Poincaré's quasi-Kantian position. Motivated as it is not only by the problem of theoretical change in the history of science, but also by reflection upon quantum mechanics and general relativity, one might expect that Ladyman's eliminativism with regard to individual objects and intrinsic properties entails a reductive physicalism. However, the project developed in *Every Thing Must Go*, whilst granting to physics a definite epistemological and ontological priority, aims at a unification of the sciences which proceeds by way of consilience rather than reduction. But how is it possible to defend a physics-based metaphysics which holds that there are no such things as 'things' without impugning the reality of the everyday lifeworld or the special sciences, both of which are of course richly populated with individual objects? This is just one of the questions explored in our interview.

As physics uncovers more and more of a reality which simply does not work according to the models of our intuitive picture of the world, cognitive neuroscience increasingly reveals the extent to which these models themselves depend more upon the nature of our cognitive processing systems than on the world which they purport to represent. In an interview with **THOMAS METZINGER**, we discuss the radical thesis presented in his magnum opus *Being No One* that 'no such things as selves exist in the world: Nobody ever *was* or *had* a self'.[49] Metzinger discusses the bases for and the ramifications of his position, and responds to criticisms of his radical eliminativist position with regard to the existence of selves. Like Ladyman, Metzinger too takes philosophers to task for prioritising 'armchair intuitions' about the nature of the mind over scientific discoveries, but also reflects upon the evolutionary provenance of such intuitions; that is, how 'certain forms of self-deception were adaptive and became superbly robust, spilling over into the enterprise of philosophy and science itself'. But if the 'Copernicanism' of neuroscience consists in its subtracting the real substrate of our 'selves' from all intuitive 'visibility', rendering it incongruent with our biologically-inherited patterns of thinking and rebarbative to efforts to 'make sense' of the world and our fellow humans, is there any way for our *cultural* fabric to 'digest' its deliverances? Here, Metzinger proves more than ready to address the potential social and cultural ramifications of his position: Against the frightening possibilities many find in the prospect of an accomplished science of the mind, he argues that, although it will inevitably entail a profound transformation in our self-understanding, advances such as his self-model theory present potential opportunities for ushering in a new age where society and politics can be informed by scientific discovery: 'Enlightenment 2.0'.

This question of the 'toxicity' of Copernican thought makes explicit the connection between this volume's theme and that of its predecessor, with its suggestion that between the adventures of reason and the comfort of intuition may lurk 'concept horrors' best explored in the imaginings of writers and artists.[50] Painter **NIGEL COOKE**'s contribution gives us a glimpse of the territory in-between the two volumes. Over the last decade, Cooke's massive canvases have introduced their viewers to an 'interzone' of representation, where painting enters into a dialogue with its past that eschews the progressive dialectic of artistic modernism. With formal ingenuity and wit Cooke has invented a mode of landscape painting that depicts the landscape of representation itself, a plane of uneasy coexistence (cartoon vegetables suck disconsolately on cigarettes alongside severed heads smiling up from the undergrowth, before vast walls which serve as a support for weeping graffiti brains ...) whose effect is to disturb and parody received notions of the relative sophistication, meaning and value of images. The contemporary painter, suggests Cooke, faces an objectively 'moronic and hysterical'[51] situation which can be transmuted into opportunity only through a concerted complicity with its groundless condition. Accordingly, Cooke's latest works, exhibited as 'New Accursed Art Club', found the character of 'The Painter' himself absorbed into the canvas, as a vagrant stumbling through the remains of representation, a derelict motif encompassed in his own disorienting predicament. The new paintings Cooke has made for this volume of **Collapse**, entitled 'Thinker Dejecta', are haunted by a close relative of this shambolic figure – The Thinker, overburdened and undermined by what Julian Barbour describes as 'a journey into the totally unknown, in which shock

a 'techno-thriller' inspired by Metzinger's work, which prompted Metzinger himself to warn, in hyperbolic mode: 'You should think twice before reading this – there could be some scientific and philosophical possibilities you don't want to know!'

[51] See the absorbing interview with Cooke in S. Malik, D. Leader, N. Cooke, and S. Goetz, *Nigel Cooke: Paintings 01-06* (London: Koenig Books, 2006).

follows shock', slogging on with an intellectual labour that only ever seems to bring him further down in the world. Nonplussed by the puzzling connection between his lofty intellectual flights and the degeneration of his condition, Cooke's thinker drifts in a wasteland, Kant's 'rational delight'[52] a distant memory, while a psychotic sun (recalling Shawcross's experiments in helio-eccentrism) beats down mercilessly on his fevered brow. As in Cooke's other work, the density of reflection compacted into these apparently cartoonish vignettes indexes the entangled motivations, glories and disorienting turns of philosophical thought, that enigmatic mélange of hubris, masochism, and addiction: A compulsion, Cooke suggests, whose crowning insight will be that man was ever its confused instrument rather than its master.

While many philosophers, especially those unacquainted with philosophy of science, assume that naturalism (or 'scientism') entails a radical kind of physicalist reductionism which is constitutively incapable of doing justice to the manifest image of the *Lebenswelt*, as James Ladyman makes clear, and as biologist **JACK COHEN** and mathematician **IAN STEWART** also affirm in our interview 'Alien Science', scientific realism does not necessarily entail impugning the status of everyday macroscopic objects. Cohen and Stewart's collaboration has produced a series of popular science books which are remarkable in their scope, epistemological subtlety and conceptual inventiveness. Much of their work has consisted in a close examination of the development in recent decades of the sciences of chaos and complexity, which seek to systematically account for the 'emergence' of high-level natural properties on the basis of the abstract microphysical principles described by modern science. It seems that reductionism alone cannot do justice to these macroscopic patterns, which retain a certain autonomy from their component parts, but the precise nature of their 'emergence' remains a vexed question. While Ladyman prefers to avoid the fuzzy term 'emergence' altogether, Cohen and Stewart have sought to develop a theory of emergence that avoids the invocation of any 'magical' properties that would not be fully causally determined by their underlying microphysical properties. Against the accusation that emergentism privileges those features which happen to be phenomenologically available to human beings, they insist that, far from being an anthropomorphic notion, emergentism rather registers our ignorance of the underlying mechanisms. If much of what we perceive is the result of the 'quick and dirty feature-detection systems' of the brain, this is only one of the ways in which nature, of which the human brain/mind is a part, 'collapses' the underlying chaos. Crucially for Cohen and Stewart, it is not only the human brain that perceives nature in terms of high-level structures and features: Just as the scientist singles out specific features of Mars, such as its orbit, position and mass, and models those features mathematically as a curve, a point and a number respectively, so does the sun 'see' Mars as a concentrated mass exerting a gravitational force, rather than as a collection of atoms and force vectors.[53] The human brain is a part of the natural world and the way in which it 'caricatures' the things which it comes into contact with is not unique to it. This recalls a position familiar to readers of **Collapse**, as Graham Harman has developed in previous volumes the argument that with an understanding of this 'caricaturing' one can prosecute realism in the macroscopic domain.[54] However, while Harman continues to reserve a special place for an a priori metaphysics which would treat of 'the same world as that of the various sciences but in a different manner',[55] and holds the categories of the manifest world to retain an ontological primacy over the discoveries of science, the work of Ladyman and Cohen and Stewart alike seems to suggest a metaphysics developed entirely on the basis of the deliverances of the sciences, without need for any such metaphysical 'overlay'.

[53] Jack Cohen and Ian Stewart, *The Collapse of Chaos: Discovering Simplicity in a Complex World* (London: Penguin Books, 1994), 430.

As well as recounting the origins and significance of the key conceptual innovations of their co-authored works ('complicity', 'Ant Country', 'privilege', 'extelligence', etc.), and discussing the relationship of their work to philosophy, in our interview Cohen and Stewart also explain their criticisms of what they see as the overly conservative and unimaginative nature of much of contemporary astrobiology and cosmology. If, according to Rovelli, the strength of science 'resides not in any putative certainties uncovered, but rather *in a radical awareness of our ignorance*', one of the ways which contemporary cosmology has attempted to take into account the intrinsic limitations of the human perspective has been in terms of what is known as 'anthropic reasoning', which aims to rigorously take into account the fact that our evidence about the universe is restricted by the conditions which must be in place for us to be there to observe it in the first place. As Barrow and Tipler have pointed out, the Copernican revolution itself was initiated by the application of what is known as the 'weak anthropic principle': Copernicus rendered redundant the hypothesis of epicycles by explaining that the retrograde motion of the planets was due to the 'anthropic selection effect' consequent upon the fact that we were observing the planetary motion from the vantage point of the moving earth.[56] Subsequent to Brandon Carter's invention of the term 'anthropic principle' in the early seventies, an increasing number of scientists have turned to anthropic reasoning in order to account for the extreme unlikelihood of the advent of life and intelligence which seems to follow from the 'fine-tuned' nature of the fundamental physical constants of our universe. However, Cohen and Stewart have long been critical of the very idea that our universe is in any way 'fine-tuned', and in our interview they explain their charge that the very notion rests on little more than 'bad logic'.

---

[54] See Harman's 'Vicarious Causality', in R. Mackay (ed.), **Collapse** II (Oxford: Urbanomic, 2007), 171-205 ', and 'On the Horror of Phenomenology: Lovecraft and Husserl', in **Collapse** IV, op. cit., 333-64.

[55] 'Vicarious Causality', op. cit., 174.

While Cohen and Stewart are vitriolically dismissive of the very idea of the putative 'fine-tuning' of our universe, astrophysicist **MILAN ĆIRKOVIĆ** remains unconvinced by their criticisms, which he regards as being largely based upon the outdated idea that anthropic reasoning is necessarily teleological and anthropocentric. In his 'Sailing the Archipelago', Ćirković sketches the philosophical foundations for an epistemologically and scientifically sophisticated approach to anthropic reasoning and fine-tuning which, while acutely aware of the kinds of problems emphasized by Cohen and Stewart, does not lead to the conclusion that anthropic reasoning is forlorn. Against the accusation that anthropic reasoning necessarily entails an anti-Copernican privileging of *Homo sapiens*, or of terrestrial, carbon-based life as the only possible kind, Ćirković begins his inquiries by taking seriously the idea that our own universe is only one region of a possibly infinite multiverse, thus 'dealing with the widest conceivable ensemble in which our universe can be embedded, in order to avoid assigning it any special status'. If during the history of science since the Copernican revolution we have witnessed the loss of special status for ever-wider and more encompassing environments, Ćirković suggests that now, in the twenty-first century, 'we should not be surprised to learn that there is nothing special about the whole of our cosmological domain – our universe – either'.

---

[56] Barrow and Tipler, *The Cosmological Anthropic Principle* (Oxford: Oxford University Press, 1986), 3-4.

Comparing contemporary cosmologists, astrophysicists and astrobiologists to the great explorers of the European Age of Exploration, Ćirković argues that the fact that earlier voyages had come to the premature conclusion that our island is the only habitable one in no way suggests that the voyage itself is misbegotten: If they were wrong, it was not because of 'some ulterior and heinous agenda [...] [I]t was perfectly reasonable for them to think so – we might compare their rationality to that of a hypothetical ancient philosopher of Easter Island, pondering the huge ocean surrounding his home'. If we think of the range of possible parameters governing the laws of physics as describing a landscape of 'possible universes', then, Ćirković suggests, we have so far only charted the very small ‘island’ that is ‘habitable’ for us. However, this does not mean that we live on the *only* island in this space, or that the type of life for which our universe appears to be ‘fine-tuned’ is the only type of life possible. If a little humility is appropriate, argues Ćirković, given that we are only beginning to chart this vast topography, it would be absolutely premature to conclude that we are its only possible inhabitants.

While the detractors continue to accuse anthropic reasoning of anti-Copernicanism, Ćirković finds in their criticisms the relics of a Cartesian dualism which fails to take into account the fact that human bodies are ‘measuring instruments whose self-selection properties *must* be taken into account, just as astronomers *must* take into account the self-selection properties of optical telescopes’.[57] After all, if the human animal is fully a part of the natural world which science investigates, having evolved through various physical, chemical and biological processes, how can one justify ignoring their properties, or failing to take into account the very special nature of the conditions which had to be in place for those properties to evolve in the first place? Is all science which takes account of the nature of human beings *eo ipso* ‘subjective’ or ‘anthropocentric’, or might it not rather be the case that science *needs* to mention human beings in order to *be* objective?[58] Thus, far from being a prop to human self-importance, a 'reactivation [of] finalist thought', or a reversion to the doctrine of Copernicus' own teleological anthropology (as Quentin Meillassoux argued in an earlier volume of **COLLAPSE**),[59] Ćirković's work demonstrates how anthropic thinking merely stems from a deepening of the 'Copernican imperative' which imposes itself once physics begins to consider landscapes of physical possibility beyond the actual universe. Thus, contrary to the critics' charges, the anthropic programme of the investigation of observation selection effects, far from amounting to a 'betrayal of the Enlightenment', is rather 'the continuation of the Copernican revolutionary spirit in overcoming not only the apparent specialness of the Earth and of life on it, including humans, but of the very special laws, associated mathematical structures, and our universe in general'. While it may take generations of astrobiologists before quantitative precision is reached, Ćirković argues that the enormity of the task 'should not detract from the fact that the problem is a well-defined one from the start'.

---

[57] ‘Such telescopes tell us about the radiation in the visible band of the electromagnetic spectrum, but it would be completely illegitimate to conclude from purely optical observations that all of the electromagnetic energy in the Universe is in the visible band. Only when one is aware of the self-selection of optical telescopes is it possible to consider the possibility that non-visible radiation exists. Similarly, it is essential to be aware of the self-selection which results from us being *Homo sapiens* when trying to draw conclusions about the nature of the Universe.’ (Barrow and Tipler, *The Anthropic Cosmological Principle*, op. cit., 3-4).

Whereas Cohen and Stewart enthuse about the possibility of the discovery of alien life – '[f]inding aliens (even bacteria) would be fantastic [; c]omplex aliens, at the level of a snail, would be amazing [; t]he level of intelligence of a cat – awe-inspiring' – transhumanist philosopher

---

[58] This is a point forcefully made by Sherrilyn Roush in her excellent 'Copernicus, Kant, and the anthropic cosmological principles' in *Studies in the History and Philosophy of Modern Physics* 34 (2003), 5-35. This paper also sheds further helpful light on many of the connections between Copernicanism, Kantianism, and anthropic reasoning explored in this volume.

[59] Q. Meillassoux 'Potentiality and Virtuality', in R. Mackay (ed.) **COLLAPSE II** (Oxford: Urbanomic, 2007), 55-81, 78.

Nick Bostrom argues in 'Where Are They?' that such findings, far from being a cause for celebration, would in fact augur very badly for the future of the human race. Bostrom's work as an analyst of 'existential risk' here dovetails with his work on anthropic thinking, as he unravels the consequences that would follow from such a discovery. Were traces of life discovered elsewhere in our solar system – on Mars, say, or upon Jupiter's moon Europa – most people would of course be thrilled, perhaps even comforted to learn that we are not entirely alone in the cosmos. However, for Bostrom, no such news could be good news, and indeed the more complex life we found, the more depressing that news would be. On the basis of two well-known facts – namely, that our galaxy alone harbours billions of potential germination points for life, and yet that decades-worth of searching for traces of extraterrestrial life has consistently failed to detect any signs of intelligent life – Bostrom argues that there must exist a 'Great Filter' that renders the existence of advanced technological civilisations exceptionally improbable. The crucial question then becomes where this Great Filter might be located. If it is located in our evolutionary past, this would be good news, since it would suggest that the great fluke which ushered us into existence had already taken place. However, should we ever find evidence of life on other planets, and especially were we to find it to have independently evolved somewhere in our own solar neighbourhood, this would of course suggest that life is commonplace, meaning that the Great Filter still awaits us: a prospect that would leave our future chances of survival looking very bleak indeed.

Speaking about his early exposure to physics and mathematics, artist **Keith Tyson** has said: ‘once I could see myself as part of a network everything became clearer’.[60] But in using the structures of scientific experience to ‘explore the myth of individuality’, he adamantly maintains his right to creatively transform them. His work thus marries a keen attentiveness to the concepts of contemporary science with a tendency to appropriate them into conceptual ‘machines’ to steer his artistic practice, as in projects such as *Geno/Pheno* (2005).[61] Refusing to grant scientific conceptualisation any overarching role in his work, he instead sites it within a broader, transversal network of ideas whose dazzling multiplicity is reflected in works such as 2006’s *Large Field Array*. This work – whose title adverts to the Very Large Array on the plains of San Agustin, New Mexico, where twenty-seven massive radio telescopes combine their multiple viewpoints to produce high-resolution astrophysical imaging – consists of a ‘rhizome’ or ‘huge soup’ of elements arrayed in a vast grid according to lines of affinity traced by Tyson himself, and reflecting his own multiple interests, memories and experiences. Thus Tyson extends the cosmological ambition to address ‘everything’ to extra-physical forces: ‘We are the things that are carrying those forces. Including history. Including energy. All sorts of fields. So everything is the sum of all possible paths. And that’s what [*Large Field Array*] is about. All those intricate interrelations.’

The conceit of Tyson’s contribution to **Collapse** lies in making a short series of images stand for a similarly megalomaniacal ambition – that of employing the entire history of the universe as a pool of 'time-based media'. The work draws upon the Einsteinian model of four-dimensional spacetime, or 'blocktime' – Tyson explains: 'If we accept blocktime as a working model in which any position in time, space and possibility is a frame within a 3D animation, we could splice together single frames in the celestial cutting room as a kind of random sampler'. Ironically, the presentation of such an 'animation' as a series of stills on the page is all the more apt given Julian Barbour's thesis of the 'unreality of time', entailing as it does a modification of Einsteinian blocktime whereby Tyson's 'animation' would cease to be animated at all. Meanwhile, the inclusion in the images delivered by his 'random splicing' of disproportionately many images of our planet is perhaps as unlikely ('uncopernican') as it is comforting: but, as Tyson – an erstwhile gambler – has said, he doesn't believe in chance, or at least only as a name for a human constraint which is there to be explored. Here again, the universal reach of science is twinned with a sanguine acceptance of the artist's own unique location in time, space and history.[62]

Of course, for many philosophers the notion of 'Copernicanism' as entailing a subtraction of scientific knowledge from the conditions of intuition will seem utterly alien. For 'Copernicanism' in philosophy has become a byword for what is in effect understood, in Kant, to be a recentring of the universe precisely around the power of cognitive synthesis harboured by the knowing subject. By making phenomenal reality orbit around a transcendental subject which is supposedly distinct from and yet indissociable from the human subject, Kant is deemed to have inaugurated what Quentin Meillassoux has recently denounced as a 'Ptolemaic counter-revolution' that re-installed human experience at the centre from which Copernicanism had displaced it.[63] However, in his 'The Phoenix of Nature: Kant and the Big Bounce', **Martin Schönfeld** presents us with a vivid picture of Kant profoundly at odds with this recent popular characterisation of him as a conservative, anti-Copernican thinker, by way of an examination of his 1755 work *Universal History of Nature and Theory of the Skies.*[64] Here we encounter a radically anti-anthropocentric, anti-Christian, naturalistic, and speculatively audacious Kant who pushes 'Copernicanism' to its limits, abolishing the hand of God from the Newtonian cosmos and introducing history and evolution into it. This is Kant as the Copernican revolutionary who as early as 1755 strongly anticipates the fundaments of what became the Standard Model of modern cosmology only in the 1920s. More specifically, Schönfeld introduces the reader to an undeservedly neglected idea from Kant's early cosmology ('the Phoenix of Nature'), one which takes on surprising significance in view of the very latest hypotheses and findings of contemporary (quantum loop) cosmology: 'the Big Bounce'.

---

[63] See Quentin Meillassoux, *After Finitude: An Essay on the Necessity of Contingency*, Tr. R. Brassier (London and New York: Continuum 2008), Chapter Five.

[64] It is strongly recommended that this essay be read in connection with Schönfeld's more in-depth treatment of Kant's 1755 work and its context in his superb 'Kant's Early Cosmology' in G. Bird (ed.), *A Companion to Kant* (Oxford: Blackwell, 2006), 47-62. See also Schönfeld's *The Philosophy of the Young Kant* (Oxford: Oxford University Press, 2000), and his entry for the *Stanford Encyclopedia of Philosophy*, 'Kant's Philosophical Development', online at http://plato.stanford.edu/entries/kant-development/

To accompany his piece, Schönfeld also provides a new translation of the chapter from the *Universal History of Nature* in which the Phoenix of Nature appears: 'On Creation in the Total Extent of its Infinity in Space and Time'. This work will certainly come as a surprise to those familiar only with Kant's critical works, or with a contemporary *doxa* aligning Kant unproblematically with an idealism that is constitutively incapable of breaking out of the 'correlational circle' in order to take the measure of the 'Great Outside'.[65] Its astonishingly prescient cosmology of 'island universes' and the birth and death of 'worlds' presents a truly awe-inspiring vision of the cosmos, thought-provoking even to those familiar with the latest developments in astrophysics. Popper called the *Universal History of Nature* 'one of the greatest contributions ever made to cosmology and cosmogony',[66] and as Schönfeld notes, Kant's daring conjectures have been to a significant extent vindicated in their general outlines by modern cosmology.

Embarking as it does upon what Kant, with tangible enthusiasm, calls 'the greatest and most awesome subject imaginable',[67] the *Universal History of Nature* sketches what Blumenberg calls 'a monumental panorama of the endless evolution of worlds, still from the point of view of a faculty of reason that, so to speak, adopts the standpoint of divinity and identifies itself with the divine view of the world'.[68]

[68] Hans Blumenberg, *The Legitimacy of the Modern Age* (Cambridge, Mass.: MIT Press, 1985), 212. The following passage contains several close paraphrases of Blumenberg's text; sources are indicated in the footnotes.

Here man appears, 'among the immense vortices of the self-propagating worlds, as but an ephemeral episode. This whole infinite extravagance of a "world of worlds", of galaxies and supergalaxies, is conceived in relation to omnipotence, as the latter's demonstration of itself to itself'.[69] Though still partially in thrall to the teleological metaphysics of the 'great chain of being', and speaking of 'degrees of perfection', it is clear that Kant sees no connection between man's history and this process of improvement. Whereas Romantic thinkers such as Friedrich Schlegel took the unfinished nature of the world to indicate that man's vocation was to play a role in completing it, for Kant there is no such anthropocentric teleology in play. That the world is ever 'unfinished' has nothing to do with human action but is due to its having been created by an inexhaustible power, which Kant speaks of, in Spinozistic fashion, as either 'God' or 'Nature'. Man, 'who seems to be the masterpiece of creation', finds his place with the 'world of worlds' precisely where there is an already 'perfected world structure', among others still in the process of coming into being or disintegrating.[70] In a startling anticipation of Ćirković's position, Kant holds that the universe is not made for man, but that the infinite process of the evolution of worlds creates temporary 'habitable zones'. Habitability is not a lasting and ubiquitous feature of the bodies of the universe, but is only the result of the fact that the total reality, in analogy to the distribution of habitability on the earth, also has its 'temperate zones'.[71]

[70] Ibid., 212-3.

[71] Blumenberg, *The Genesis of the Copernican World*, op. cit., 591.

As Kant explains in one of his letters, it was the cosmological problem of the finitude or infinitude of the universe that led him to his theory of knowledge in the first *Critique*,[72] and as Schönfeld suggests, one should not underestimate the degree of continuity between this early work and the later critical philosophy. This is borne out by a comparison of the two passages below, the first from the *Universal History of Nature*, the second from the *Critique of Pure Reason*:

> If the size of a planetary system in which the Earth is hardly seen as a grain of sand fills the understanding with astonishment, how delightfully astounded we will be when we examine the infinite crowd of worlds and systems which fill the totality of the Milky Way. But how much greater this wonder when we know that all these immeasurable arrangements of stars once again create a numbered unity, whose end we do not know and which is perhaps, like the previous one, inconceivably large and yet, once again, only a unit in a new numbered system. We see the first links of a progressive relationship of worlds and systems, and the first part of this unending progression already allows us to recognize what we are to assume about the totality. Here there is no end, but an abyss of a true infinity, in which all capacity of human thought sinks, even when it is uplifted with the help of mathematics.[73]

> The observations and calculations of astronomers have taught us much that is wonderful; but the most important lesson that they have taught is has been by revealing the abyss of our ignorance, which otherwise would never have been conceived to be so great. Reflection on the ignorance thus disclosed must

> produce a great change in our estimate in the purposes for which our reason should be employed.[74]

If Rovelli suggests that the problem is that we 'use concepts that we have developed in our very special environment (characterized by low velocities, low energy ...) and we think the world as if it was all like that',[75] this is also a sentiment shared by Kant, who puts the order and structure we see down to 'anthropic' considerations regarding our spatial and temporal location in the universe. Whereas 'from our perspective in the Universe, it would seem as if we looked at wholly completed creation and, so to speak, at an infinite array of systematically connected world-orders [...] if we could step outside this evolved sphere, we would see chaos' and a 'random scattering of elements'.[76] Similarly, in Part Three of *Universal History of Nature*, itself devoted to speculations regarding the inhabitants of other planets, Kant compares the worldview of human beings with that of a louse inhabiting the head of a vagrant:

> Let us judge in an unprejudiced manner. This insect, which in its way of living as well as in its lack of worth expresses very well the condition of most human beings, can be used for such a comparison with good results. Since, according to the louse's imagination, nature is endlessly well suited to its existence, it considers irrelevant all the rest of creation which does not have a precise goal related to its species as the central point of nature's purposes. The human being, who similarly stands

[76] See Kant, 'On Creation ...', this volume, 396.

> infinitely far from the highest stages of being, is sufficiently bold to flatter himself with the same imaginative picture of his existence as essential.[77]

It should be borne in mind that Kant never completely abandoned even some of the most speculative views expressed in the *Universal History of Nature*. Thus, in the celebrated conclusion of the *Critique of Practical Reason* he speaks of 'an unbounded magnitude with worlds upon worlds and systems of systems',[78] and in the *Critique of the Power of Judgement* likewise of 'the Milky Way, and the immeasurable multitude of such Milky Way systems, called nebulae'.[79] Indeed, as **Iain Hamilton Grant** points out in his 'Prospects for Post-Copernican Dogmatism', it would be a matter of considerable irony if a *soi-disant* 'Copernican' revolution in philosophy should have put an end to the project of a *Universal History of Nature*. However, there is of course no doubt that the critical philosophy brought about a hugely significant transformation in Kant's epistemological approach, and in this regard Grant suggests that the 'dogmatism' against which Kant contrasts his critical conception of philosophy is none other than the naturalism of his own 'pre-critical' writings. This raises a number of important questions regarding the relationship between transcendental philosophy and a naturalistic ontology, questions which are skilfully examined in Grant's paper.

---

[77] *Universal Natural History and Theory of Heaven*, op. cit., Part Three, 'An Attempt, Based On Natural Analogies, at a Comparison Between the Inhabitants of Different Planets'.

[78] *Critique of Practical Reason* (Cambridge: Cambridge University Press, 1997), 133 [*Ak*: 162].

[79] *Critique of the Power of Judgement* (Cambridge: Cambridge University Press, 2000), 140 [*Ak*: 256].

Exploring the paradoxes and antinomies that result from the attempted combination of transcendental philosophy and a physics-based ontology as it arises in Kant and post-Kantianism, Grant finds transcendental philosophy, as defended by both Kant and Fichte, to be itself 'dogmatic' according to its very own criteria. Taking into account Kant's late revisions of his critical philosophy in the light of advances in the natural sciences, Grant argues that transcendentalism's susceptibility to naturalistically driven ontological change inevitably pushes a rationally consistent transcendental philosophy in the direction of Schelling's 'transcendental naturalism'.

In 'A Throw of the Quantum Dice Will Never Overturn the Copernican Revolution', **Gabriel Catren** also draws upon Schelling's *Naturphilosophie* in proposing what he calls a 'speculative overcoming' of recent quasi-Kantian interpretations of quantum mechanics. Rather than being limited to a mathematical account of the correlations between 'observed' systems and their 'observers', or pointing to the inherent 'transcendental limits' of physical knowledge, Catren argues that quantum mechanics furnishes a complete and realistic description of the intrinsic properties of physical systems, an ontology which exemplifies the Copernican deanthropomorphisation of nature. While Catren is sympathetic to Quentin Meillassoux's suggestion that Kant's Copernican revolution ultimately eventuated in a kind of 'Ptolemaic Counter-Revolution', and argues for an explicitly 'pre-critical' approach to the interpretation of quantum mechanics, he is also severely critical of Meillassoux's a priori arguments regarding 'necessary contingency'. Indeed, Catren finds Meillassoux guilty of recapitulating a paradigmatic gesture of 'Kantian' critique: that is, of presuming to stipulate, in purely philosophical terms, what physicists will never be able to do. Through an ingenious appropriation of resources from the history of philosophy and the models of mathematical physics, Catren succeeds in providing an interpretation of quantum mechanics that seems able to satisfy the often mutually-exclusive requirements of philosophical intelligibility *and* mathematical coherence. While Catren's interpretation is doubtless controversial in its suggestion that it enables us to recover the 'classical' notions of 'decontextualised objects' and 'intrinsic properties' from within quantum mechanics – a thesis which would seem to run directly counter to the kind of interpretation developed by the likes of Ladyman – there is no doubt that Catren's essay presents a challenging thesis, and outlines a project for a 'speculative physics' that deserves to be followed closely.

If in Cooke's errant figure of the dejected cognitive labourer wandering a scorched earth we see the human thinker bent under the epochal 'humiliations' dealt by Copernicus, Darwin and Freud, **ALBERTO GUALANDI** discovers a certain 'errancy of the human' to be the very source of its cognitive prowess. In contrast to Grant and Catren's bold proposals for a Schelling-inspired 'speculative physics' which would push the Copernican deanthropomorphisation of nature to its limits, Gualandi argues for the need to establish a new 'circular and communicative' theoretical interface between science and philosophy which would be capable of both integrating the natural and the human sciences and overcoming the antinomy between Kant's 'Copernican revolution' and that of Copernicus himself. Exploring the features common to certain speculative philosophies of nature in 1960s France and problems facing current evolutionary biologists, Gualandi introduces a 'neotenic conception of the human animal' capable of taking into account what he calls 'the necessary complementarity between the *critical* and *eccentric* dimension of man'. While it would be impossible to do justice to this superbly rich and thought-provoking paper here, we would note that it brings into focus the many reasons why the notion of 'Copernicanism' is still important for philosophy and for the sciences today, and will certainly repay careful and repeated reading.

Whereas Gualandi insists on the human and embodied nature of all knowledge, and adverts to the unsurpassability of Kant's Copernican revolution, **PAUL HUMPHREYS** proposes that computational science is fast displacing humans from the centre of the epistemological universe, a revolution which will eventually produce as radical a transformation in our self-image as did the Copernican revolution itself. Beyond the implicitly anthropocentric epistemologies of an empiricism which would limit the knowable to what is accessible to a set of biologically-contingent devices and a realism whose criterion of reality invokes independence from human minds, Humphreys considers the possibility of a purely automated science for which the division between what is and what is not accessible to the human mind would be, ironically, an entirely 'artificial' one. While Kant rejected the idea of obtaining knowledge of the world as it is in itself on the grounds that it would require us to have 'a faculty of knowledge altogether different from the human [...] in other words, that we should be not men but beings of whom we are unable to say whether they are even possible, much less how they are constituted',[80] Humphreys' paper suggests that such beings may already be among us. If we have not yet entirely relinquished the hope of one day being able to 'finally penetrate the barriers that have stood between between us and the rest of reality', Humphreys argues that the sooner we understand how 'some instruments and some computers confront reality non-conceptually' the better. Might not this also prove to be a necessary part of the task of what Metzinger calls 'Enlightenment 2.0'? In this regard, it seems appropriate to close this introduction with a citation from the conclusion to Kant's *Universal History of Nature*: 'We do not really know what the human being truly is today. [...] How much less would we be able to guess what a human being is to become in the future!'

We would like to conclude by offering our most sincere gratitude to all of our contributors and collaborators, whose wholehearted commitment to this project has consistently been above and beyond the call of duty. We hope that the fragments of the 'big picture' assembled in this unique volume will compensate them for their efforts.

Sky
Earth

Anaximander's Legacy[1]

Carlo Rovelli

I. ANAXIMANDER

It all started twenty-six centuries ago, on the coast of what is now Turkey. Every civilization in the world had an image of the world like that in Fig. 1: *Up* there is the sky, *down* there is the Earth. Below the Earth, to prevent it from falling, there is more Earth. Or else a turtle standing upon an elephant, as in some Asian myths; or maybe gigantic columns, like those mentioned in the Bible. This was the picture of the world common to the civilizations of Egypt, Babylon, India, China, Africa; as well as to the Jews of the Old Testament, the natives of Australia and North America, the Mayans, the Incas, and every other ancient culture of which we have a trace.

---

[1] Freely extracted from the forthcoming book, *Anaximander of Miletus and the Nature of Scientific Thinking*. (Text revised by Ray Brassier and Damian Veal.)

Then came a man, living in Miletus, who suggested something else: the world is rather more like this:

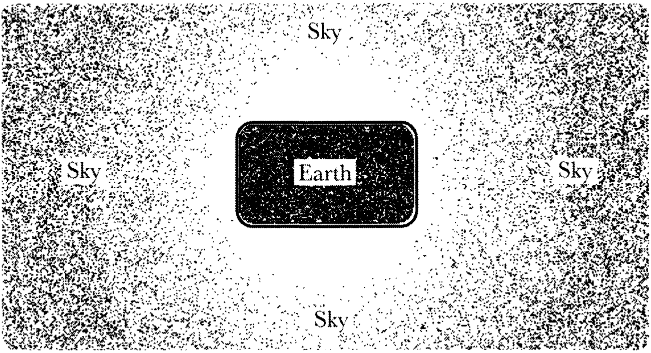

Figure 2

That is, the sky is not just above us: it is all around us, including below us. The Earth is not the lower half of the universe: it a big stone, floating in the middle of the sky without falling. The man who proposed this major change in our understanding of the world was Αναξιμανδρος, Anaximander. In a rather short time, Anaximander's idea is recognized as correct. Only a generation later, Pythagoras, or someone of his school, improves upon the model by making the Earth spherical (an easy move, after Anaximander's step). Another couple of generations later and Plato, in the *Phaedo*, presents the idea as the most reasonable one and shortly after Aristotle proposes very convincing arguments, based upon observations, in support of the idea. The idea becomes universally accepted around the Mediterranean, and subsequently by all other civilizations, one by one, as they come into contact with it.

How was Anaximander able to make this gigantic leap in our understanding of the world? At first sight, it doesn't seem too hard: evidence abounds. For instance, the Sun sets in the west in the evening and reappears in the east in the morning: so where does it go? More precisely, if we observe a starry night, we see all the stars rotating slowly and magnificently around the Polar star. Some stars, close to the Pole star, are always up in the sky; others, a bit further away, hide for a while beyond far-away mountains; still others disappear for a short while beyond the horizon, only to reappear a little further east. Isn't it rather obvious that there must be empty space, down there, so they can keep going?

Image: © Josch Hambsch

Anaximander to understand that the sky above us continues below us? Civilization had existed for millennia by Anaximander's time. Why had nobody realized this earlier?

Why had no-one among the Egyptians, or Babylonians, or Jews, all undoubtedly clever people, noticed this? Why had the Chinese, with their splendid civilization and with several millennia of the Imperial Astronomical Institute, failed to understand that the Earth floats in the sky, so that they had to wait until as late as the seventeen-century, when Jesuit astronomers arrived in China, to realize it? Evidently, this was not such an easy step to take. So why was it so hard?

Because it contradicts common-sense. If there is nothing below the Earth, why doesn't the Earth fall? Anaximander's genius, and the reason why he was able to convince the world of his idea, consisted in coming up with an answer to the obvious objection to the idea of a floating Earth. His answer was marvellous: The Earth does not fall, because it has no *reason* to fall; things fall 'towards the Earth', but the Earth itself has no preferred direction or any special reason to fall. In other words, Anaximander proposed a completely new grammar for understanding the spatial structure of the universe. There is no longer a universal 'up' and 'down' (Fig. 3) – rather, 'up' and 'down' are *relative* to the Earth (Fig. 4). Things fall towards the Earth itself. Hence the Earth itself has no special reason, or preferred direction, for falling.

Anaximander's greatness consists in this: Starting from remarkably little, he redraws the entire cosmos. He transforms the very grammar of the way we understand the universe, subverting the meaning of 'up' and 'down', which had provided the most intuitive and elementary way of organising space and reality for countless generations of humans hitherto.

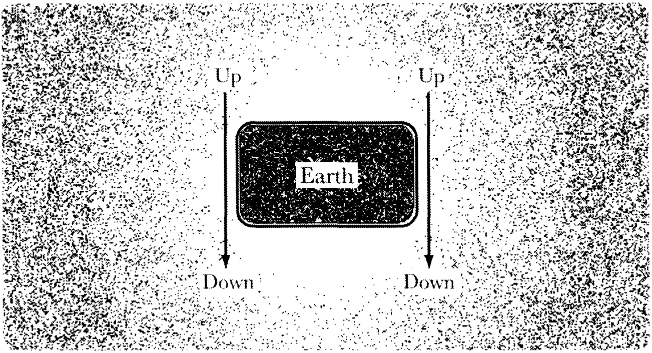

Figure 3

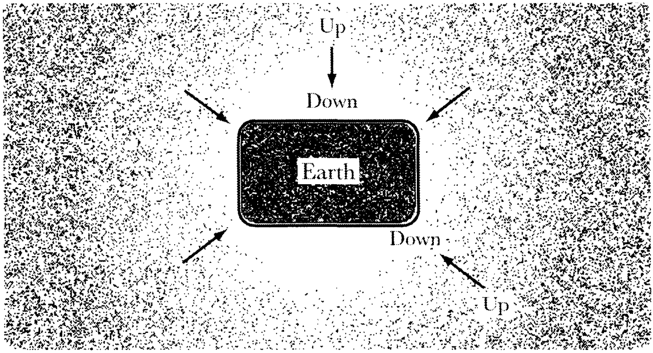

Figure 4

No, says Anaximander: *Things are not as they appear to us.* The world differs from the way it seems at first sight. Common sense is deeply misleading. Our intuitions are based upon our limited experience: Think more openly, look further away. There is no 'up' or 'down' in the universe; only in our little garden do things seem to be that way.

When properly utilized, reason liberates us from our partial and limited point of view, profoundly restructuring our understanding of the world. This is what science does.

Anaximander's idea that the Earth is in fact floating in the middle of the sky alone would suffice to make him one of the most decisive figures in the entire history of human thought. But in fact his heritage is considerably broader than that. Anaximander also paves the way for astronomy, geography, meteorology and biology. With Thales, he initiates the naturalistic enquiry which, over the centuries, will slowly evolve into modern science. More importantly, however, in doing so he also inaugurates the very process of *rethinking the image of the world* – the path of investigation of the world which is based on the rebellion against what appears obvious; the recognition that knowledge begins with the realisation that common sense can be misleading. In this regard, Anaximander is one of the major wellsprings of all scientific and, more generally, rational thinking.

II. WHAT IS SCIENTIFIC THINKING?

Scientific thinking is a passionate exploration of new ways of conceiving the world. Its strength resides not in any putative certainties uncovered, but in *a radical awareness of our ignorance*. It is this awareness that allows us to continuously question what we think we know, and thereby to learn more. Such thinking is fluid and capable of continuous evolution. It has the capacity to subvert the order of things and to continuously redraw the world.

Scientific theories are not arbitrary constructions whose only truth content lies in their verifiable and verified consequences. Rather, they are the eyes through which we view and understand the world. Science can neither be grounded in, nor its truth-value reduced to, its verifiable predictions – nor to its hypothetical-deductive method, or to its operational protocols. Quantitative predictions, calculations, techniques, operations, falsifications ... all these are *tools*: important and incisive tools; pieces of evidence; instruments of clarity; ways to try to avoid mistakes; techniques to detect false assumptions; and so on. But they are only *tools*, and only some of the tools which come into play in science. They serve an intellectual activity whose substance is to be found elsewhere.

Numbers, techniques, predictions and calculations are all indispensable for suggesting, for testing, for validating, for confirming, and for utilizing discoveries. But there is nothing technical in the content of these discoveries: the Earth floats in space; the cosmos does not pivot around the Earth; matter is made up of protons, electrons and neutrons; there are hundreds of thousands of galaxies in the universe, each made up of hundreds of thousands of stars; rainwater comes from the evaporation of water from seas and rivers (another discovery by Anaximander); fifteen billions years ago the entire visible universe was compressed into a ball of fire; similarities between parents and children are transmitted by a DNA molecule which is carried by each of our cells; our brains comprise a million million synapses that jump when we think; the unlimited complexity of chemistry basically consists in combinations of simple electrical forces between protons and electrons; since all living beings on our small planet have common ancestors, we are related to ladybugs ... These are all *facts* about nature which were deeply counterintuitive for our common-sense worldview not so long ago; facts which have effected a profound change in our vision of the world and of ourselves. Their scope and relevance is vast, direct, and inhuman. This is what science is.

Scientific knowledge is the ongoing process that brings about an in-depth modification of our way of conceptualising the world by selectively questioning our assumptions and beliefs the better to propose new ones that promise to be more effective. Scientific thinking consists in re-drawing the world anew over and over again before our eyes. It is learning how to look further; learning how to conceive and envisage the world differently. Science is primarily an exploration of new forms of thinking.

Thus, before being technical, science is visionary. Anaximander, who was ignorant of mathematics, was the necessary step before we could arrive at the sophisticated mathematical astronomy of Hipparchus and Ptolemy. Nicholas of Cusa and Giordano Bruno opened up the way for Galileo and Hubble. The young Einstein asked what the world would look like if observed while riding a light wave, and told us in his best work of popularization that he saw spacetime as a huge jellyfish. Science is always conjuring up new worlds, before going on to discover that some of these fit reality better than our old prejudices.

Science's reconceptualisation of the world is continuous. The great conceptual revolutions, like those of Anaximander, Copernicus, Darwin or Einstein, are only its most visible moments. But the way in which we structure and conceive our understanding of the world today is profoundly at odds with that of a citizen of Babylon three thousand years ago.

And this transformation is the result of the gradual accumulation of many small modifications. Some of these steps represent definitive acquisitions: We no longer dance when we want it to rain. Others are only partially established: we know that our universe has been expanding rapidly for around fifteen billion years, but some still stubbornly insist that the world has only existed for six thousand or so years simply because the Bible says so. And other steps have been made by the research community, but have yet to become common currency: The structure of spacetime revealed by Einstein's work is quite different from the one with which most of us are familiar. It will take time to adapt, just as it took time to accept Copernicus' discovery. But the world will keep changing around us, as we discover more and more aspects of it. The visionary force of scientific thinking lies in its capacity to see further, and to expose our innumerable prejudices.

But in our attempt to think the world and to uncover hitherto unexpected aspects of it, we never begin entirely from scratch: We are always guided by the enormous amount of knowledge that we have already acquired. Our awareness that there might be something wrong with this knowledge – with the very conceptual structure in terms of which it is formulated – does not alter the fact that this knowledge provides the basis for everything we think and is the source of our intellectual strength. We can only transform it from within; not from the outside. As we compare this knowledge with our ever-changing experience of the world, as we confront different parts of our vast and complex body of knowledge with one another, our knowledge is increased, consolidated and strengthened.

This means that scientific advances are never simply directed against past knowledge: They are always also grounded in it. When Einstein was faced with the problem of the apparent incompatibility between Maxwell's equations and Galilean relativity, he could, in good Kuhnian spirit, easily have dismissed the relativity of velocity; or, alternatively, the universal validity of Maxwell's equations. But that's not what he did. Rather, he steadfastly maintained his faith in the validity of the core factual content of *both* the Galilean and Maxwellian theories – precisely that core factual content which is supposed to change freely at every step forward, in Kuhn's *vulgata*. But Einstein assumed that these theories should be valid well beyond the regime in which they had been tested. The combination of these seemingly contradictory hypotheses was sufficient for him to derive a new synthesis, special relativity; but at the price of dropping a *third* hypothesis, previously always tacitly assumed but never made explicit: that of the absolute value of simultaneity. Until that moment, this third hypothesis had been construed as an *a priori* of thinking, a veritable pillar of common sense.

Einstein did not carry out his revolution by discarding the old theories and proposing a new one. Rather, he carried it through by taking the old theories seriously and by questioning something in the general conceptualisation of the world. He did not proceed by finding new solutions in a game with clearly defined rules, but rather by changing the rules of the game itself.

This is not an isolated example. Copernicus does not abandon Ptolemaic astronomy in order to re-organise the phenomena; rather, he absorbs Ptolemy's system in depth, preserving epicycles and deferents, and it is within the folds of the old theory that he discovers the golden key – something unexpected should be abandoned: the fixity of the Earth. Similarly, Dirac predicts anti-matter on the basis of his faith in special relativity and quantum theory; Newton derives universal gravitation by taking seriously Kepler's third law and Galilean acceleration, virtually without *any* additional empirical input. In Einstein's greatest *coup de génie*, 1915's general theory of relativity, he discovers that spacetime is curved solely on the basis of special relativity and Newtonian gravity. And so on. In all of these examples, it is faith in the factual content of previous theories (the factual content that much contemporary philosophy of science disdains) which leads to discovery. And it is common sense that pays the price at each step.

From this perspective, we cannot identify three centuries of Newtonian science with science *simpliciter*, as we so often do. Rather, the past three centuries have been more like a pause along the way, in the wake of a major success. In questioning Newton's conceptualisation of the world, Einstein did not question our ability to understand reality. He simply made a new beginning upon the existing path; the path that had been that of Maxwell and Faraday, of Newton, of Copernicus, of Ptolemy, of Hipparchus and of Anaximander; questioning over and over again our naïve image of the world in order to keep deepening and refining it; recognising that our common sense is superficial and misleading; that the world is more vast, more beautiful and ultimately more understandable than the little garden of our everyday intuitions. We learn to see further by recognizing our mistakes.

Each of the steps taken by these great figures, as well as those taken by many more minor figures, gradually transforms our image of the world – sometimes in great depth. They can even modify the very rules upon which we base our understanding of the world. At each step, we obtain an improvement in our map of reality, drawn in new colours. At each step, we understand the world a bit better.

Let me briefly return to Anaximander. Among his numerous major contributions to human knowledge, there is one which is purely methodological; one which is perhaps the least evident but also the most far-reaching. Anaximander has a 'Master': Thales. Thales was a major figure in ancient Greece, so revered as to be included in the list of the 'Seven Sages', together with Solon, who wrote the first democratic constitution of Athens, and various other personages that the Greeks considered as their *maitres à penser*. Anaximander is a follower of Thales: he shares the same interests, the same naturalistic approach to the world, the same topics of investigation ('What is the principle out of which everything is made?'). It is clear that Anaximander's reflection begins from and is deeply rooted in that of Thales. This is not unusual in the ancient world, where great Masters (Confucius, Jesus, Pythagoras ...) often founded influential schools and had famous disciples (Mencius, Paul of Tarsus ...). But although such disciples would sometimes develop and expand the ideas of their Masters, they would certainly never question those ideas. Mencius never questions Confucius. Paul never questions Jesus. Not that criticism was absent from the ancient world: it was very present indeed, and sometimes bloody: just read what the

Bible has to say about Babylon's great culture. But there was no third way between ferocious criticisms and reverential study. This is where Anaximander's attitude towards Thales initiates a new approach. Anaximander accepts Thales' idea that everything in the world consists in a single 'principle', but rejects the idea that this principle could be water, as it was for Thales. He accepts the idea that the Earth might be like a large floating stone, but removes the ocean upon which Thales thought it was floating. And so on ...

This is to say that while Anaximander relies heavily upon Thales' speculation, building upon it, he does not hesitate to declare that Thales is wrong. There is a sophisticated theory of knowledge underlying this attitude: The realization that we can have *valuable* knowledge, but at the same time that this knowledge can be partially wrong; and, in any case, that it can always be improved. In other words, Anaximander realises that knowledge can be uncovered by relying upon what we know, but also by uncovering *mistakes* in what we believe to be true. This is precisely the attitude of any good detective. In adopting it, Anaximander opens up the path for the immense development of subsequent speculation, which is the basis of Greek philosophy and modern science. After Anaximander, Pandora's box is open: Every Greek feels free to challenge the received view and to propose an alternative in what might at first appear to be a cacophony, but is in fact the most spectacular development in the emergence of a formidable array of new and better ways of understanding the world.

III. The Current Revolution and Loop Quantum Gravity

Today, we are in the midst of a reconceptualisation of the world which is likely to prove every bit as far-reaching as those of Anaximander and Copernicus. Einstein's theory has effected a profound transformation in our understanding of what space and time are. Quantum mechanics has effected a profound transformation in our understanding of matter and energy. These theories are now almost a century old, and have been very widely corroborated: they furnish the basis for much modern technology. But we have not yet attained a fully credible theory within which the two theories can be coherently understood in their relation to one another. Our understanding of the world has once more become deeply confused and fragmented. There is currently an ongoing theoretical effort striving to discover the new sought-for synthesis and there are candidate theories which look promising, for instance the theory on which I work, called *loop quantum gravity*.

These theories demand of us, once again, a readiness to transform our understanding of the world in depth. Just as Anaximander asked his contemporaries to accept the idea that the Earth can float without falling, and Copernicus asked his contemporaries to believe that the Earth rotates on itself at great speed, once again our common sense is going to be questioned; once again, we cannot *and must not* rely too much upon our simple intuition, if we want to be able to see deeper into reality. We will have to rely instead upon our observations, our capacity for rational thought, and our imagination. We will have to rely upon our vast body of acquired knowledge about the world, which codes everything we know about it, even as we recognise that several pieces of the story might in fact be wrong. And we will have to keep searching. We have no fixed ground. Our intelligence is our only guide.

General relativity has taught us that space and time form a quasi-material continuum; a field very much like the electromagnetic field: A sort of fluid that suffuses everything. We have learnt with quantum mechanics that all fields, including the spacetime field, must have quantum properties, which means a granular structure and a probabilistic dynamics.

Loop quantum gravity is a tentative mathematical theory for describing this *granular* and *probabilistic* spacetime. The best way to understand it is to think about it as a substance formed by quanta ('atoms of space'), which fluctuate probabilistically and which are not to be thought of as immersed *in* space and evolving *in* time, but rather as what makes up space and whose relations make up time.

The resulting picture of the world is one in which space and time are no longer primary concepts. They are not the 'home' of reality and the 'flow' along which things happen. Rather, they are approximate and derivative concepts, like the concept of temperature or the concept of the surface of a liquid: Concepts which disappear in a more elementary description of reality. *Can we think the world without time?*

IV. IS THERE NO TIME IN THE FUTURE?

Time is the hardest concept to modify in our intuition. We already know all too well from Einstein's work the extent to which our intuition that time flows equally and universally all over the universe is badly misleading: Two twin brothers can travel separately and meet again when they are different ages.

But if our current tentative theories about quantum gravity are correct, we will have to modify a good deal about our concept of time. Indeed, we will have to learn to think the world at its most elementary level (at least for the time being) *without making any reference to the notion of time at all.* This means that we must reinterpret dynamics as a theory of relations between variables, instead of as a theory of the evolution of variables in a preferred independent time-variable.

The only fragment that remains of the book written by Anaximander reads:

> εξ ων δε η γενεσις εστι τοις ουσι, και την φθοραν εις
> ταυτα γινεσθαι
> κατα το χρεων
> διδοναι γαρ αυτα δικην και τισιν αλληλοις της αδικιας
> κατα την του χρονου ταξιν

Its (disputed) translation is as follows:

> All things originated one from the other, and perish the ones into the others,
> following necessity
> And they render justice to one another, and pay one another for injustice
> in conformity with the order of time

Much has been read into this text. It is possible that this is the first enunciation of the idea of natural law. Pythagoras, shortly after, added the remarkable idea that laws must be written in mathematical terms; Plato instructed his students to search for such mathematical laws in the regularities of the heavens, leading to that spectacular scientific success which is Alexandrian astronomy – which, in turn, once revived by Copernicus, paved the way for modern science.

For twenty-six centuries, Anaximander's prescription to search for laws that describe how things change *in time* ('in conformity with the order of time') has been strictly adhered to, and has proved immensely fruitful. But it may be that we now need to challenge even this most fundamental rule of the game: Today, the fundamental physical laws are no longer being sought in the form of laws of evolution in time, but rather in the form of laws of relations between physical variables.

In doing so, we are not betraying Anaximander's legacy, but celebrating it once again: knowledge is not attained by revering the Masters and scrupulously following their lead; it is attained by absorbing at the most profound level what the Masters have to teach, the better to uncover where they might be wrong.

V. WHAT DO WE KNOW WITH CERTAINTY?

If the condition of our search for knowledge is the recognition of the limitation and the uncertainty of our present understanding, where can we find the solid ground upon which to base our certainties?

I think that, notwithstanding the impressive amount of knowledge that we have been able to accumulate so far, there is nothing in our knowledge that is ultimately grounded in a solid bedrock. And it is my opinion that the attempt by philosophical inquiry to unearth a metaphysical or methodological starting-point from which some certain indubitable knowledge could be derived, is misbegotten.

We have learnt that there is no such thing as 'pure experience' – the experience which Bacon elevated into the principle of his new religion of science – capable of grounding certainty. Nor is there any 'pure reason' of the kind upon which Descartes hoped to rely, but which led him to such an erroneous physics. Both Baconian empiricism and Cartesian rationalism had a polemical objective: to supplant the tradition upon which Scholasticism had relied with a new source of epistemic validity. The explosive and liberating power of these philosophies freed thinking from the prison of tradition, reawakening the freedom of ancient Greek inquiry and opening the doors to modernity. This openness to criticism is their immense legacy. But today we know only too well that there is no absolutely certain foundation upon which to ground all our knowledge. Every time we believed ourselves to have uncovered one, we have been disappointed. Neither pure experience, nor pure reason, nor a transcendental inquiry into the conditions of knowledge, nor strict verificationism, nor anything else will be able to provide us with an absolute guarantee against the pervasive influence of our faulty ideas and limited assumptions.

But the antiscientific irrationalism that pervades so much of contemporary culture is, in my opinion, as short-sighted as the eighteenth-century faith in scientific certainties: the lack of certainty is not the weakness of scientific thinking, but rather its strength. Scientific theories are not credible because they are definitive: they are credible because they represent the best knowledge about the world we are able to attain at any given moment. And it is precisely because we refuse to consider them definitive that we are capable of constantly improving them. As John Stuart Mill put it in *On Liberty*:

> The beliefs which we have most warrant for, have no safeguard to rest on, but a standing invitation to the whole world to prove them unfounded.

'Reality' itself is a flimsy notion, but what an effective one! How could we do without it? Our thinking is thinking about reality. We refer to it, relate to it. What else we are dealing with if not reality? Everything we know is something we know about reality. That about which we know – that is reality. It is that which continues to surprise us, to disclose itself to us anew, and about which we imagine there is still so much to learn – perhaps aspects of which we will never learn about or be able to understand. Reality continues to appear to us other than we had thought. And in the evolution of our love story with it lies the growth of our knowledge. It has aspects of a dream but, as in the marvellous words of Hippolyta:[2]

> … all the story […] told over,
> And all their minds transfigur'd so together,
> More witnesseth than fancy images,
> And grows to something of great consistency;
> But, howsoever, strange and admirable.

I think that our mistake is to fear this fluidity and to search for certainty. To select a fixed point upon which our restlessness could finally come to rest would be not only naïve, indeed counterproductive for our thirst for knowing; it would be dishonest. Science is the human adventure that consists in exploring novel ways of thinking the world; it should always be ready to subvert any certitude we think we have gained thus far. The fearful side of this adventure consists in fully recognizing and assuming our ignorance. It is my conviction that to accept our ignorance is not only the royal road to knowledge: It is also the most honest and the most beautiful one. The emptiness and the corrigibility that it entails do not make our life and our knowledge less meaningful: They make it more precious. It is an adventure that was begun twenty-six centuries ago, so far as we can tell, by Anaximander – or, if not by him, by somebody else living in Miletus at that time. It is, I think, amongst the most enchanting of human adventures.

And of course, yes: Anaximander was right:

The View from Nowhen

Interview with Julian Barbour

In his first major book, The Discovery of Dynamics (1989), *theoretical physicist and historian of physics Julian Barbour described the process of discovery and progress in science* as *'a journey into the totally unknown, in which shock follows shock'.*[1] *A decade on, in* The End of Time (1999)[2] *he put forth in popular form his thesis, developed over some decades, regarding what he had come to believe would be the next great shock to our commonsense picture of the world – namely, that the concept of time would cease to have any role in the foundations of physics. More starkly expressed, Barbour predicts that the next great revolution in our understanding of the universe will entail the realisation that time does not exist – a thesis which, if true, would be shocking indeed. The question, of course, is whether it is true; and, if it is, how we could ever possibly find a way to test and confirm such a seemingly outrageous hypothesis. In our interview with Barbour, we ask him about the motivations which led him to develop his radical position, the paradoxes and problems which arise in trying to make sense of it, and his own eccentric position in relation to mainstream academic theoretical physics.*

---

[1] Julian Barbour, *The Discovery of Dynamics: A Study from a Machian Point of View of the Discovery and the Structure of Dynamical Theories* (Oxford: Oxford University Press, 2001), 58; originally published as *Absolute or Relative Motion? Vol. 1: The Discovery of Dynamics* (Cambridge: Cambridge University Press, 1989).

[2] Julian Barbour, *The End of Time: The Next Revolution in our Understanding of the Universe* (London: Weidenfeld and Nicolson, 1999).

Collapse: Before tackling the details of your thesis regarding time and timelessness, we would like to start by asking you to say something about your own intellectual journey 'into the totally unknown'. Your reading of Ernst Mach's *The Science of Mechanics* in 1963 seems to have been a crucial turning point. You have said that this book made a profound and lasting impression on you, and it's clear that your subsequent intellectual trajectory has been profoundly marked by Mach's ideas. What was it, precisely, about Mach's book that you initially found so compelling? Was it simply the persuasiveness of his arguments against the Newtonian notion of absolute space, or was there more to it than that?

Julian Barbour: It is certainly true that Mach's writings, especially his *Mechanics*, were extremely important in providing the stimulus for my life's work. I found his critique of Newton's notion of absolute space totally persuasive. Perhaps luckily for me, Mach never formulated in any detail an alternative to it, though he certainly gave suggestive hints. The field was therefore free for me to develop. However, in doing so I departed strongly from Mach's ideas about how one should actually do science. In his view, one should carefully observe natural phenomena, identify characteristic phenomena that recur repeatedly, and formulate science as the economic representation of these phenomena. Mach distrusted theory, especially the attempt to advance in science by means of analytical dynamics. In fact, I totally disregarded this aspect of Mach's thinking when formulating Machian theories. They rely heavily on the techniques of analytical mechanics, above all the principle of least action.

Mach was also important in strengthening my belief – already formed before encountering his work – that the Newtonian concept of time needed revision. Few people have noted that the first half of Mach's critique of Newton's concepts deals with time and includes his remark: 'It is utterly beyond our power to *measure* the changes of things by *time*. Quite the contrary, time is an abstraction, at which we arrive by means of the changes of things.'[3] Much of my work has been devoted to the transformation of this qualitative statement into a quantitative theory of duration. This also finally led me to the radical ideas presented in *The End of Time*.

C: One might be surprised here that you neglect to mention the fact that, while Mach indeed did not himself develop a detailed alternative to the Newtonian notion of space and time, *Einstein* certainly did, and that he did so on the basis, at least in part, of Machian ideas. While the degree to which, and in what precise respects, Mach's ideas exercised an influence on Einstein have long been a matter for debate, there is no doubt that Einstein himself was of the opinion that Machian epistemology had exercised a crucial influence upon him. In an article from 1916 he even went so far as to say that certain passages from Mach's *Mechanics* 'show that Mach clearly recognised the weak spots in Classical Mechanics and was not far from requiring a General Theory of Relativity', adding that '[i]t is not improbable that Mach would have come across Relativity if, at the time when he was in his prime, physicists had concerned themselves with the significance of the constancy of the speed of light'.[4]

---

[3] E. Mach *The Science of Mechanics: A Critical and Historical Account of Its Development*, trans. K. Menger & T. J. McCormack (Chicago: Open Court, 1988), 273.

Whether or not Einstein was correct about this, the popular view seems to be that, while Mach's ideas undoubtedly influenced Einstein to some extent, those ideas were nevertheless motivated by a combination of ideas which have long since been rendered obsolete by developments in both physics and the philosophy of science: not much more, then, than a mere historical curiosity. However, your early comparison of Mach's ideas with the papers which Einstein had written while he was developing his general theory of relativity led you to the conclusion that Einstein had been formulating his theory on lopsided foundations, and that it was the problems relating to what Einstein called 'Mach's Principle' which had been inadequately developed. You have described Mach's Principle as the idea that 'the locally observed inertial properties of particles arise not from some independently existing absolute space, but rather from the combined effect of all the dynamically significant masses in the universe.'[5]

JB: Yes, the idea that only *relative* configurations exist; a position that had already been adopted, incidentally, by Leibniz.[6]

C: So you set out to explore what a truly 'Machian theory', wholly faithful to this principle, might look like. In order to directly confront problems that Einstein had failed to think through sufficiently, it would be necessary to return to first principles regarding the Machian problem of inertia. But how would this rethinking of the Machian foundations of general relativity ultimately lead you to the radical thesis of the total elimination of time and change from fundamental physics?

JB: You correctly summarize the reasons why I felt that it was necessary to go back to first principles. I very soon came to the conclusion that, while what Einstein had done in creating general relativity was brilliant, he had not clearly formulated what needed to be done in order to implement Mach's ideas directly. This led me to hope that a direct approach might lead to a new theory of gravity different from Einstein's. For several years Bruno Bertotti and I worked to create such a theory, only to discover that the theory we had found was general relativity in an unfamiliar guise. This was initially a disappointment for both of us; for a while I turned to politics, while Bertotti turned decisively to space-based searches for gravitational waves. Luckily for me, Lee Smolin encouraged me to consider the implications of our work for attempts to create a quantum theory of gravity. As the years pass, I become more and more hopeful that the Machian aspects of general relativity that Bertotti and I uncovered will prove to be useful in that regard.

I arrived at my radical idea in two stages, the first of which involved a theory of time in classical physics, the second a consideration of the implications of the insights gained in the first for a quantum theory of the universe.

A key notion in classical dynamics treated by the methods of variational mechanics is the configuration space of a closed dynamical system. It is the collection of all possible configurations that the system can have. One can take such a system to model a universe. In Newtonian particle dynamics, a configuration is defined by the separations between the particles as well as by the position and orientation of the complete collection of particles in absolute space. The first step to a Machian theory is to insist that the separations alone define the configurations. The Machian (relative) configuration space of the universe, then, is the set of all such relative configurations; I call it the RCS (of the universe). A *history of the universe* is any curve in its RCS.

Now we must think about time. According to Newton, it is absolute and flows uniformly without any reference to what is happening in the universe. But we could never say that time passes if we did not observe change. The hands of a clock must move. Moreover, the curve in the RCS is a record of *all* changes in the universe. There is no further change not already coded in the curve that would enable us to say how fast the universe moves along it. History is not the curve traversed at some speed; it *is* the curve.

In this Machian kinematics, the dubious aspects of Newtonian dynamics have been eliminated: overall position and orientation have been eliminated, as has the ‘invisible flow’ of time. However, geometrical separations are retained and so too is a unique succession of configurations. This is not a really radical change, since succession of configurations is the most important feature of time that we gain from direct experience. Using this Machian kinematics, Bertotti and I were able to create a Machian theory that differs in its predictions from Newtonian theory when applied to the complete universe but is able to reproduce Newtonian theory for a subsystem of the universe like a galaxy or the solar system.

The radical step comes when one considers potential applications to a quantum theory of the universe. In my view the greatest revolution in physics occurred when Schrödinger introduced his wave function. In classical physics, we have curves in some configuration space traversed at some speed with respect to an external time; in Schrödinger's wave mechanics we have a wave function on the same configuration space, and the wave function varies with respect to the same external time. But if there is no external time and we want to retain the notion of a wave function, which has been so outstandingly successful, it seems to me that we must take seriously the idea that in the quantum mechanics of the universe we have a *static* wave function defined on some relative configuration space. There is no external time with respect to which it can evolve.

The question then is how to make sense of that!

C: One of the ways in which you have attempted to make sense of it is by picturing this 'relative configuration space of the universe' in terms of what you call 'Platonia', which you describe as a kind of timeless and frameless arena comprising 'the collection of all possible Nows'. Before trying to come to grips with that, however, perhaps we can take a moment to unpack a little of what you have just said regarding the reasons you came to suspect that failure to resolve Mach's problem regarding inertia (with which Einstein had struggled between 1907 and 1918, but ultimately abandoned) might be intimately connected to the obstacles confronting the attempt to construct a workable quantum theory of gravity. You came to the conclusion that the lack of progress in resolving certain problems in the foundations of dynamics related to Mach's Principle, on the one hand, and stagnation in the field of quantum gravity research, on the other, might have a common origin. Einstein had favoured an indirect approach to the Machian problem based on his conviction that the history of science had demonstrated the impracticability of dispensing with coordinate systems. But the logic of Mach's own approach seemed to require precisely that they be dispensed with, in order to formulate the laws of motion directly in terms of relative distances and relative velocities without recourse to any distinguished local frames of reference. In effect, this would amount to a direct implementation of Mach's Principle, according to which the inertial properties of local matter are determined by the overall matter distribution in the universe. It was Einstein's early neglect of such explicitly *cosmological* considerations – that is, considerations regarding the universe as a whole understood as a single dynamical entity – which, you suggest, resulted in a failure to appreciate the deep 'relational' structure of general relativity. Could you spell out a little more what this strongly 'relational' interpretation of general relativity entails, and in what way you regard the previous failure to appreciate it as having posed a fundamental obstacle to progress in quantum gravity and quantum cosmology research?

JB: This is a longish story, so I will only give some of the essentials. From about 1911 Einstein always thought in terms of curved four-dimensional spacetime and believed that, if he could find a law describing the structure of spacetime that had the same form in all coordinate systems, Mach's requirement would be automatically satisfied. This is because such a law would not single out any special coordinate system in which the laws of nature take a distinguished simplest form in the way Newton's laws do in an inertial frame of reference. Einstein called his requirement the principle of general covariance and was convinced that it had deep physical significance. However, soon after general relativity had been created, Kretschmann pointed out that any law that makes physically meaningful statements about the world must be expressible in a generally covariant form. Einstein immediately accepted this argument and argued, rather feebly I believe, that it still had great heuristic value. It is also worth mentioning that the most important part of Einstein's theory, his tensor field equations, were not created by him but were taken over more or less intact from mathematicians. He did make one brilliant modification to the Ricci tensor that his friend Grossman proposed, but he never 'unpacked' the tensor that he employed (the Einstein tensor) to see exactly what it does do. Unlike Newton, he did not create his theory in its entirety *ab initio.*

To see what actually happens in general relativity, you have to work out how the structure of three-dimensional space changes as you move through spacetime. This was first described at the end of the 1950s by Dirac and Arnowitt, Deser, and Misner (in the ADM Hamiltonian formalism developed as a first step to the canonical quantization of general relativity). Without realizing there was any connection with this work, around 1979 Bertotti and I started to think what a Machian theory of the evolution of three-dimensional Riemannian geometry would be like. We constructed a theory in which not only spatial change but also time would be relational, only to discover a year later that we had effectively rediscovered general relativity in a Lagrangian form equivalent to the ADM formalism. This showed that in its most basic structure GR is Machian and, moreover, in a sense not anticipated at all by Einstein. More recent work that I have done with Niall O'Murchadha, Edward Anderson, Brendan Foster, and Bryan Kelleher[7] has shown that what I call the two Machian requirements – that both time and change are relational – are extremely powerful, much more so that Bertotti and I thought thirty years ago. They lead to conditions that any Machian theory must satisfy; in the case of dynamical Riemannian three-geometry, these are extremely restrictive.

C: Your interpretation of the radically relational structure of general relativity draws heavily upon not only Mach's ideas, but also those of Henri Poincaré. It was Poincaré, you suggest, who demonstrated more clearly even than Mach what the requirements of a theory of relative motion must be. In a thought experiment remarkably reminiscent of Plato's allegory of the cave which appears in the chapter entitled 'Relative and Absolute Motion' of his 1903 book *Science and Hypothesis*, Poincaré speculates about whether there would ever have been a Copernicus to infer the motion of the earth on its axis if the latter were continually surrounded by a thick blanket of impenetrable clouds, and we thus had no means of observing the stars. Poincaré, of course, did not yet know anything of the possibilities of space travel or of non-optical (e.g. radio) astronomy; yet he argues that, while we would have had to wait a much longer time than we did for the coming of a Copernicus, 'this Copernicus would come at last'.[8] After centuries of accumulating complications analogous to Ptolemy's glass spheres in order to explain such phenomena as centrifugal forces, the flattening of the poles, the asymmetric motion of cyclones, and Foucault's pendulum experiment, suggests Poincaré, 'the long-expected Copernicus would sweep them all away with a single blow, saying it is much more simple to admit the earth turns round'.[9]

---

[7] Several papers related to this research can be accessed at Barbour's website, platonia.com.

This is a remarkable thought experiment in many ways, not least with regard to Poincaré's suggestion that we might indeed be in an analogous situation, with regard to the universe as a whole, to that of these imaginary physicists in relation to the solar system – that is, that we might be mistaking for fundamental physical constants what a greater knowledge of our cosmic environment would reveal to be merely a function of our limited terrestrial perspective.[10] However, the main questions Poincaré seeks to raise with this thought experiment concern the Newtonian notion of absolute motion:

> If the sky were covered with clouds, and if we had no means of

> observing the stars, we might, nevertheless, conclude that the earth turns round [...] And yet, would there in this case be any meaning in saying that the earth turns round? If there is no absolute space, can a thing turn without turning with respect to something; and, on the other hand, how can we admit Newton's conclusion and believe in absolute space?'[11]

Would you like to comment on this thought experiment, and to say why you regard Poincaré's epistemological reflections on relative and absolute motion to have been so crucial in working out the necessary requirements for formulating a fully relational mechanics?

JB: Personally, I do not find this particular discussion quite so significant as the one, also in *Science and Hypothesis*, in which he pinpointed the way Newton's absolute space shows up in the evolution of the observable separations between the bodies of the solar system: the separations and the rates of change of the separations do not suffice to predict the future evolution as one would expect if only the separations had physical significance. Poincaré notes that even if astronomers could not see the stars, but only the sun and the planets, they could deduce absolute motions from their observable positions. The same thing holds, *mutatis mutandis*, for the example in which the earth is completely covered by clouds. The observable motions of the bodies that one can see can be represented so much more simply if one postulates an invisible absolute space. Poincaré was profoundly troubled by this, but being a conservative scientist he concluded that we must simply accept this fact that is so ‘repugnant to the philosopher’. It is odd that he nowhere (to my knowledge, certainly not in *Science and Hypothesis*) mentions Mach, and did not conjecture that the universe as a whole might satisfy his improved form of the relativity principle free of the repugnant feature.

---

[11] Ibid., 89.

Reading your quote from Poincaré again, I note his question ‘can a thing turn without turning with respect to something?’ This suggests to me that he was unaware of the notion of an inertial system that Ludwig Lange had introduced in 1885 and to which Mach had given considerable prominence in later editions of the *Mechanics.* Lange had shown how an inertial system is determined by observable separations of material objects; objects meaningfully rotate relative to the matter-determined inertial system. The concept is sophisticated: moving matter itself determines the frame of reference in which the laws governing the motion take their simplest form. Mach still felt that although Lange had put Newton on a sound epistemological basis, his mechanics was not relative enough; this was a gut intuition that Poincaré shared.

Coming back to his analysis and why I think it is so important: because it provides a precise criterion that a Machian theory must satisfy. Consider a system of bodies. A relative configuration of these bodies, taken to represent the universe, is determined by a set of separations between them. The set of all relative configurations forms the relative configuration space (RCS) of the system. For mechanics to be fully rational, in Poincaré’s view, a point in the RCS and a rate of change of that point in the RCS should determine the evolution uniquely. Such data do not suffice to do that in Newtonian theory because they contain no information about the angular momentum in the system; that is coded in the velocities in absolute space, which are not uniquely determined by the relative velocities. Poincaré still kept an external time in his analysis and spoke of the rate of change of the relative separations. In a timeless Machian theory, there should not be any such external time. Therefore, the condition for a fully Machian theory should be: a point and a *direction* at that point in the RCS of the universe should suffice to determine the evolution. Although Einstein read *Science and Hypothesis* closely, Poincaré's analysis seems to have made no impression on him. He never formulated Mach's principle in such a way. I think all the innumerable arguments about Mach's principle would never have arisen had Einstein been sensitive to what Poincaré had written. In a closed universe (for which arbitrary unnatural boundary conditions do not arise), Einstein's theory perfectly satisfies both parts of the Machian condition. Only if one insists that size should be relative does a very curious non-Machian feature of general relativity show up: expansion of the universe should have no meaning, in flagrant contradiction to all the successes of the modern theory of the expanding universe. Scale is absolute in general relativity – a last vestige of Newton's absolute space.

C: Are you claiming, then, that the observable universe is *not* in fact expanding? If that is the case, how then to account for the masses of mutually corroborative evidence, starting with cosmological redshift observations, which suggest that it is?

JB: I admit that much evidence supports the theory of the expanding universe very impressively. The point that I want to make is that this is mysterious. A notion of absolute size is built into the mathematics of general relativity and matches observations very well. In accordance with our present picture, the universe is doing *two* things: it is getting larger and changing its shape (it is becoming more inhomogeneous). I would be much happier with a theory in which the universe is only changing its shape and through a presently unknown mechanism this is giving rise to the effects currently explained by expansion. I live in hope of finding such a theory, or stimulating someone to do so, but am not optimistic given the success of the standard model.

C: But even if such an explanation someday becomes possible, so that we drop the hypothesis of expansion and are left only with the idea that the universe is 'changing shape' and 'becoming more heterogeneous', how is it possible to think the latter without presupposing notions of time and motion? Or to put the question in more general terms, how, in a theory according to which there is no time, change or motion in the universe, is one to account for the apparent ubiquity of such phenomena? Doesn't the suggestion that time, motion and change do not really exist run the risk of landing oneself in a rather extreme form of idealism? One might of course say that such experiences are an 'illusion', but even illusions – indeed, we might even say, *especially* illusions – require explanations, and all the more so when what is being claimed to be illusory is that which we have always taken to constitute the fundamental fabric of reality.

JB: Your question only becomes acute when we pass from classical physics to my conjecture of a static quantum universe. In this context, we have to understand how our familiar notions of time and motion arise. Now evidence for time and motion comes in two forms. First, we directly see things move; second, we deduce passage of time and change from records, which in themselves are unchanging. The latter evidence for time is no threat to my idea. As to the former, I think it need be little different from the fact that we see colour. Scientists do not think colour exists in the physical world but do not deny that it is somehow given to us in consciousness. I put motion on a par with colour. Since Galileo, we have had the distinction between primary and secondary qualities. The primary qualities, related to geometry, shape, and motion, are believed to exist in the material world while colours and sounds exist only as mental states. The primary qualities are believed to 'excite' the secondary qualities in our minds. Scientists work happily with the division of qualities and the conjectured relationship between them. I am proposing that motion should cease to be a primary quality and become a secondary one.

C: But even if we can somehow make sense of the idea that motion is a secondary quality pertaining, as you say, only to mental states – a proposal which would obviously involve enormous difficulties compared to the case of colours, heat and so on – isn't it the case that those mental states themselves, those *experiences* of primary qualities, must always have a certain *temporal duration*?

JB: I do not think this is necessarily so. A theory like mine must propose structure in the physical world that is correlated consistently with experience. If I have in front of me simultaneously two snapshots showing a football match with the players and ball in slightly different positions, I can work out from that static information how each player and the ball have moved between the two snapshots. I argue that the physical correlate of what we experience as motion is stored in the instantaneous brain configuration as two (or more) such 'snapshots'.

C: Regarding 'snapshots': In *The End of Time* you claim that the world is made up of 'instants of time' which you call 'Nows', and you liken them to 'three-dimensional snapshots' such as 'could be constructed if many different people took ordinary two-dimensional snapshots of a scene as the same instant'. As an example, you write: 'I feel an itch at the same time as seeing a moving object in a certain position. All the things I see, hear, smell and taste are knit together in a whole. "Knitting together" seems to me the defining property of an instant. It gives it unity'.[12] However, again, even if it makes sense to speak of a durationless visual 'snapshot', surely hearing a sound, at least, is not something which can happen without a certain duration? Moreover, if what I see when I feel an itch is a star many millions of light-years away, while my experience of seeing the light from the star and feeling the itch might be said to be simultaneous, the idea that the star and I make up a unified 'instantaneous present' is obviously false. In this respect, then, the 'Now' would seem to be something which has its locus only in one's experience of the world, yet you are surely not claiming that reality is somehow dependent upon experience or consciousness – which, again, would amount to a very extreme form of idealism. Doubtless these questions at least partially result from taking the metaphor of a 'snapshot' too literally, but then could you say something by way of warding off such (perhaps somewhat inevitable) misinterpretations of your position? Perhaps your idea of 'time capsules' might shed some light on this?

---

[12] *The End of Time*, op. cit., 18.

JB: One can argue that all concepts in theoretical physics, including the most abstract ones in quantum mechanics, are suggested by experience. Here 'suggested' is vital. Close your eyes and open them for about half a second before closing them again. You do experience something very like seeing a snapshot. Accumulated experience then leads us to the idea that bodies have instantaneous positions in space and that a collection of bodies is characterized at each given instant by a configuration that can be likened to a 3D 'snapshot'. In the theoretical concept, geometry plays a decisive role; it holds the world together. For me the key notion is of a plurality within a unity (a deeply suggestive expression often used by Leibniz). As I employ it, the notion comes from direct experience but is honed by abstraction to a precise theoretical concept. For example, before the finite speed of the propagation of light was discovered it was natural to assume that we see everything at the same instant, even the most distant star. Astronomers take account of the speed of light to correct apparent positions and obtain instantaneous positions in some particular frame of reference. Although it is often argued that configurations at some instant lost physical significance in Einstein's relativity theories, especially the general theory, this is not true because appropriate initial data on a spacelike surface determine a complete spacetime in general relativity. The spacelike surface is in fact a 3D curved Riemannian space. Thus, after much abstraction (which nevertheless retains the essential idea of unity within plurality) my 'snapshot' becomes such a space with matter distributed within it. The collection of all possible such 'snapshots' is my Platonia, the space of possible configurations of the universe. The reason why I identify this space – the configuration space of the universe – as all-important is because it plays a central role in both general relativity and quantum mechanics. Though others might not agree, I do not see how either theory can survive if it is not retained in some form or other.

Thus, when I speak of itches and sounds experienced simultaneously with images of objects, that is only to get across the idea of an instantaneous plurality within a unity. The insistence on 'instantaneous' in the refined concept comes from the success of the notion of instantaneous configuration in both relativity theory and quantum mechanics. In *The End of Time* I attempt to close the circle and show how our experiences might be explained by the special configurations that I call 'time capsules'. If, as I conjecture, the quantum mechanics of the universe gives a high weight (probability) to time capsules, which are instantaneous configurations that contain what seem to be mutually consistent records of a past that unfolded in accordance with the currently known laws of physics, and if conscious experience is correlated with instantaneous configurations, then one can understand how experience suggests refined concepts and a theory that in turn has the potential to explain the original experiences.

C: Isn't it empirically incoherent to claim that the empirical conditions necessary in order to confirm a given hypothesis are, according to the very hypothesis itself, non-existent or illusory? In order to even qualify as a candidate theory, is it not required that the would-be theory make novel and testable predictions? And yet, doesn't the very notion of testing a prediction fundamentally presuppose the notion of time, and of the identity of a world and an observer over time? For without these, what sense would it make to say that a prediction unconfirmed at an *earlier* time had come to be confirmed or falsified at a *later* time? In this regard, the philosopher Richard Healey has suggested that your interpretation of general relativity ends up undercutting its own epistemic credentials, since 'we can have no empirical reason to believe such a theory if it cannot explain even the possibility of our performing observations and experiments capable of providing evidence to support it'.[13]

JB: Think of Copernicus: The motion of the sun across the sky and the retrograde motions of the planets relative to the stars are empirical conditions and were used by Copernicus to argue that they were illusions. Ultimately, science is not really about prediction but *explanation* and *confirmation.* A theory is confirmed by comparing in the same instant data that we call the outcome of an experiment and data that we call a record of the earlier conditions. Theories are always confirmed in the present. Geologists, for example, developed a theory of the deep past without making any experiments. All their conclusions were drawn from present data. Cosmologists are currently developing an account of cosmology in the same way. Even experiments at the LHC are ultimately interpreted by theoreticians from data sets acquired from the experimentalists. Records are always a vital part of the story. Information is all of the same kind; we divide some of it into effects and some into records.

[13] Richard Healey, 'Can Physics Coherently Deny the Reality of Time?' in Craig Callender (ed.) *Time, Reality and Experience* (Cambridge: Cambridge University Press, 2002), 308; cf. Jeffrey Barrett, 'Empirical Adequacy and the Availability of Reliable Records in Quantum Mechanics', *Philosophy of Science*, 63, 1996: 49-64; and Jeffrey Barrett, *The Quantum Mechanics of Minds and Worlds* (Oxford: Oxford University Press, 1999), esp. 162.

I may add that John Bell (of the famous inequalities) remarked, in a discussion of Everett's 'many worlds' interpretation of quantum mechanics, that 'we have no access to the past, but only to present memories. A present memory of a correct experiment having been performed should be associated with a present memory of a correct result having been obtained. If physical theory can account for such correlations in present memories it has done enough – at least in the spirit of Everett'.[14] This seems to me a complete and succinct response to Richard Healey's difficulty. It seems to me that it is for psychological reasons that people have difficulty with such a position as mine; I do not see where there is a flaw in the logic or methodology of science properly understood. Indeed Bell himself had difficulties in this respect, in my view. In later comments on Everett he says that in his opinion the 'really novel [but unappreciated] element in the Everett theory [...] is a repudiation of the concept of the "past", which could be considered in the same liberating tradition as Einstein's repudiation of absolute simultaneity'.[15] He goes on to give a wonderful account (on which I draw heavily in *The End of Time*) of how time capsules as I define them can emerge with high probability from a timeless quantum-mechanical treatment of the formation of alpha-particle tracks in cloud chambers. But when he comes to the end, he dismisses Everett's theory (despite the brilliant support his gloss has given to it) as a 'radical solipsism [...] It is always interesting to find that solipsists and positivists, when they have children, have life insurance'.[16] This is clearly rejection for psychological reasons. For my part, I am not a solipsist and retain virtually all the ontology of impeccable realists – except that ever-elusive time.

C: The mathematician and cosmologist George Ellis has charged you with 'sneaking in a standard concept of time through the back door' since the very idea of 'the reading of records in some order presupposes a concept of time operational in the mind – which surely cannot occur if the brain is part of a static, unchanging world.'[17] Ellis thus finds you guilty of exempting the mind from the physics which you claim governs the way things work, and thus of

[16] Ibid., 136.

[17] George Ellis, book review in *Studies in History and Philosophy of Modern Physics* 33, 2002: 380.

'allowing the human mind to transcend the basic worldview that is supposed to govern the way nature works'.[18] Do you reserve a special ontological place for the conscious mind?

JB: We are clearly learning a great deal about the workings of the brain, but how anything ultimately comes into consciousness is, to my knowledge, still a complete unknown. However, let me make this comment: Boltzmann's explanation for our sense of the direction of time relies on difference of structure: a state with higher entropy is perceived as being later in time than one with lower entropy. This implies that the brain compares two structures and on the basis of the structures alone decides which is later and presents it to us later in consciousness. My view is hardly different; in fact I am not sure if it is in any way different. I propose that, in the immense complexity of our brain, there are, in any instant, configurations of neurons that in the traditional view scientists would regard as occurring in a definite time-order. I am merely saying that they can be put naturally in that order solely using their intrinsic structure; in the process of presenting the stored information to us in consciousness, the brain does not need access to an externally supplied time-order. It constructs it from the information available in one instant. I put such arguments in *The End of Time*, especially Chapter Two, and still think they are reasonable, despite what George says. He argues that I allow 'the human mind to transcend the basic worldview that is supposed to govern the way nature works'. I would answer that, when it comes to essentials, I am in the good company of Boltzmann, and that the Wheeler-DeWitt equation (which is the putative fundamental equation of quantum gravity) suggests that it is the 'basic worldview' that may need to be changed.

---

[18] Ibid.

C: Ought we take this as a kind of avowal, then, that you are indeed suggesting that the mind in some way transcends the physical world? There are, of course, very many neuroscientists, cognitive scientists, evolutionary biologists and philosophers who will strongly demur at your suggestion that the nature of the relationship between consciousness and the brain is still 'a complete unknown'. But even if that *were* the case, wouldn't even a superficial knowledge of the history of science over the past two centuries lead one to expect that we are not dealing with anything essentially refractory to physical explanation here, or anything intrinsically more 'mysterious' than, say, motor control? Before the advent of molecular biology, for example, many people thought it was unimaginable that to be a living thing could consist in a particular organization of 'dead' molecules, and many today have similar difficulty imagining how consciousness could be a function of the brain, and it's hard not to see the two cases as being closely analogous. As the philosopher of neuroscience Patricia Churchland points out, '[f]rom the vantage point of considerable ignorance, failure to imagine some possibility is only that: a failure of imagination – one psychological capacity amongst others [...] It is not an interesting metaphysical fact about the universe nor even an epistemological fact about the limits of scientific knowledge'.[19] Of course, you know this very well, since your own thesis is so radically counterintuitive. But the point is that any form of metaphysical dualism just doesn't look like a scientifically respectable option nowadays.

JB: I certainly grant that very exciting advances are being made in the study of the relationship between brain activity and conscious experience. But this always leads to the recognition of *correlations.* Kepler remarked long ago that if certain phenomena are invariably correlated, this may occur for two reasons: certain of the phenomena are the cause of the others, or else all the phenomena have a common unidentified cause. Thus, it is not necessarily the case that the correlations now being found *explain* the conscious state. Your example of motor control shows that complex automata can and do exist, but I do not think that understanding of the control mechanism could ever suggest that an automaton is self-aware. As Leibniz said in his *Monadology*, '*perception* [...] *cannot be explained mechanically*, that is to say by figures and motions. Suppose that there were a machine so constructed as to produce thought, feeling, and perception, we could imagine it increased in size while retaining the same proportions, so that one could enter as one might a mill. On going inside we should only see the parts impinging upon one another; we should not see anything which would explain a perception.'[20]

---

[19] Patricia Churchland, 'Can Neurobiology Teach Us Anything About Consciousness?', *Proceedings and Addresses of the APA* 67 (4), 1993: 27.

[20] G. W. Leibniz, *Monadology* paragraph 17, in *Philosophical Writings* (London and Vermont: Everyman, 1973), 181.

Despite all the recent advances in brain research, I do not think anything overthrows Leibniz's argument.

Thus, I believe one should keep an open mind about the true connection between the brain and experience. As to metaphysical dualism, it seems to me deeply rooted in modern quantum mechanics, which posits a *wave function* defined over *the space of possible configurations* (of whatever physical system that one is considering). I do not see how one can get more dualistic than that. Moreover, the precise connection between these two remains obscure because of the profound interpretational problems in quantum mechanics. Of course, the dualism I have just mentioned is not between mind and matter, but it is still a fundamental dualism.

C: I note that when talking about the way in which the psychological impression of time and motion is created a moment ago, you spoke about the *brain* rather than the mind doing all the work, and thus seem to accept that consciousness is indeed subserved by neurobiological mechanisms.

JB: This is more or less correct. If I use the word *mind*, it is inadvertently (except in idioms). I prefer *experience* or Leibniz's term, *perception*. But I would say *correlated with*, not *subserved by*. The position that I adopted in *The End of Time* is conventional: the conscious state is correlated with the brain state, by which I mean with an instantaneous configuration (positions of atoms) of the brain. The only role of the wave function that I attributed to experience is to make it (the wave function) determine the probability of particular experiences. I am now wondering if the wave function might not play a richer part in experience alongside the instantaneous configuration. But these are all tentative ideas. The only difference between my view and the conventional one is that I remove *motion* from the overall state of the physical world with which I propose experience to be correlated. This contrasts with the standard view that correlates experience with *positions* and *motions*. Position is clearly much more fundamental than motion, for motion is change of position.

I may also mention that there are people with what is said to be a neurological malfunction that makes them see the world as a succession of snapshots. I know one such person; she is currently cured of the problem, but it was so extreme in her case that she would sometimes experience the snapshots in the wrong chronological order, so that crossing a road was life threatening. She contacted me having read my book and found that my concept of Nows resonated deeply with her experience. This suggests to me that deepest-level experience may be snapshot-like and that continuous experience is a higher-level phenomenon.

C: One might wish to maintain, in quasi-Kantian terms, that time is only a mode of intuiting reality rather than something pertaining to the world as it is in-itself. However, it's still rather difficult to see how even that mode of perception – understood as an *internally* rather than *externally* supplied time-order – can take place in a entirely static world. You say that 'in the process of presenting the stored information to us in consciousness, the brain does not need access to an externally supplied time-order', but even here one cannot help but be struck by the fact that you are still talking about a *process* – namely, a process of making comparisons and drawing inferences about relative temporal ordering. It's difficult to see how that can be squared with the idea that the physical world is entirely static – unless, that is, we somehow exempt the activity of brain from the very physical world of which it forms a very minute part, an idea which seems inherently absurd.

JB: No, I would not advocate that. Of course, I do have difficulty in expressing atemporal notions in familiar language, which is so permeated by temporality. A French man did write a whole book without using the letter *e*, but writing one using only the verb *to be* does not appeal to me. It may help to note that for millennia theologians and millions of believers have been happy with the idea that God is eternal, unchanging, and omniscient (and therefore presumably self-aware). I do not want to invoke theology to bolster a scientific theory, but this does at least show that my basic proposal is not without precedent. I believe I am part of a universe far larger than myself; I know I am self-aware; ergo I conclude that the universe is self-aware. We have long lived with the idea of the block universe that results from taking Einstein's relativity seriously. So self awareness resides in eternity.

C: What happens to the idea of *evolution* according to your theory, whether we're talking about the evolution of the universe, or biological evolution? How could a brain, for example, evolve in a purely static world, and why would it be fitted out with sophisticated but delusive experiences of a world of change in which things have happened, and indeed which are happening now? What, after all, could these experiences be *good for*? – a question for which the theory of evolution by natural selection provides an extremely plausible set of answers, but which seems inherently baffling on the basis of your own conjecture of a timeless universe.[21] Does your theory require one to 'explain away' the massive amounts of mutually corroborative evidence for evolution, just as it would seem to require explaining away all the evidence which seems to indicate that the universe is expanding, or do you think it might be possible in some way to construct a 'timeless' theory of evolution?

JB. We are talking about such big issues, we must take one thing at a time. The theory of evolution relies heavily on chemistry and that posits for the (classical) universe an extraordinarily special beginning, for otherwise there are great difficulties with the second law of thermodynamics and the arrow of time, which is deeply reflected in all of evolutionary theory. Now, in *The End of Time* I did put forward what I believe is the first potential explanation for the arrow of time from first principles. It is based on a quantum theory of the universe from which the appearance of a classical universe can in principle arise. I relate the great asymmetry of experience – between the past and the future – to an inescapable profound asymmetry in the space of possible configurations of the universe. Although my book has clearly attracted much interest because of its denial of time, virtually no one has commented on this idea.

---

[21] This objection is borrowed from Jeremy Butterfield's extensive review of Barbour's book, 'The End of Time?', *British Journal for the Philosophy of Science* 53 (2), 2002: 289-330.

As to chemistry, many researchers in quantum gravity have proposed a mechanism whereby timeless quantum gravity can be compatible with the emergence of the conditions for chemistry governed by standard quantum mechanics. Thus I think I can provide the broad framework needed for evolution to be represented in eternity. The point is that every possible configuration of the universe is present in my Platonia: actual dinosaurs in one place in Platonia and fossils of dinosaurs in different configurations in another place, both of which can in principle have high probability as measured by the wave function of the universe. In principle, that is enough to have evolution emerge. Of course, there is a huge way to go from a qualitative outline to detailed confirmation.

C: While you said you earlier that you think science is more about explanation and confirmation than prediction, you of course do not deny that any candidate theory in physics must be able to make novel predictions, and in *The End of Time* you say that 'even clear disproof of my theory would be exciting for me'.[22] Hypothetically, then, what kinds of findings might be able to disprove or falsify your theory? Could you provide examples? What would *testing* your theory involve?

JB: I am hesitant to say that my theory makes any predictions at the moment because it is as yet more in the nature of an outline of a theory. However, I do have the clear proposal that there is a static wave function of the universe that concentrates its associated probabilities on configurations of the universe that I call *time capsules*. These are static material configurations containing what appear to be mutually consistent records of a history that unfolded from a special past (highly uniform Big Bang) into the universe that we see around us. In principle, this suggestion could be supported or clearly disproved by mathematics. It is certainly the case that time capsules as I define them are ubiquitous. So this is the most obvious field for testing of my theory. I also think it is just possible that developments in brain research might support my conjecture that experience of motion is correlated with instantaneous brain configurations.

---

[22] *The End of Time*, op. cit., 17.

C: At the beginning of *The End of Time* you compare your theory of the non-existence of time to the Copernican revolution in cosmology in the following terms:

> The pattern of the first great revolution will be repeated. Copernicus, Galileo and Kepler taught us that the earth moves and rotates while the heavens stand still, but this does not change by one iota our direct perception that the heavens do move and that the Earth does not budge. Our grasp of the interconnections of things was, however, eventually changed out of recognition in ways that were impossible to foresee. Now I think we must, in an ironic twist of the Copernican revolution, go further, to a deeper reality in which nothing at all, neither heaven nor Earth, moves. Stillness reigns.[23]

A further comparison with Copernicanism appears at the beginning of the fifth chapter, where you suggest that the kind of mental preparation needed to understand Poincaré's ideas requires one to undertake a radical transformation in one's biologically-inherited mode of thinking:

---

[23] *The End of Time*, op. cit., 14.

> I hope you will be able to change from a way of thinking to which we have been conditioned by the fact that we evolved on the stable surface of the Earth to a more abstract way of thinking that would have been forced upon us had we evolved from creatures that roamed in space between objects moving through it in all directions. We have to learn to find our bearings when the solid reassuring framework of the Earth is not there.[24]

If the total disappearance of time from our worldview indeed turns out to be the ultimate denouement of Copernicanism – that is, if time itself, rather than being retained in our world-picture, albeit at some less fundamental level, must rather 'go the way of the [Ptolemaic] epicycles'[25] – what are the implications of this for our commonsense, intuitive picture of the world? Is it really possible that a creature whose imagination and cognitive capacities evolved, as you say, on the stable and reassuring surface of the earth, could ever be capable of coming to terms with the implications of such a revolution in anything more than the most purely abstract way? The philosopher Paul Churchland has suggested a way in which we might train ourselves to perceive our place in the solar system in properly 'Copernican' terms, thereby freeing not only our minds but also our *eyes* from 'the tyranny of a flat immobile Earth' and finding ourselves 'at home in the solar system for the first time'.[26] However, the prospect that we might ultimately be able to undertake an analogous experiment in the 'expansion of perceptual consciousness' in such a way as to become at home in a physical universe in which time does not exist seems not only remote, but fanciful in the extreme.

---

[24] *The End of Time*, op. cit., 71.

[25] http://www.edge.org/discourse/davies_loops.html

[26] Paul Churchland, *Scientific Realism and the Plasticity of Mind* (Cambridge: Cambridge University Press, 1979), 30, 34 and Chapter Two *passim*.

JB: Half of my ontology is very conservative and barely different from Newton's: the universe can exist in many different configurations. They can be thought of as like snapshots that a child can pick up and examine. I am not introducing a difficult concept here. A continuous succession of such snapshots is epistemologically identical to a Newtonian history of the universe if it satisfies a certain law that can be formulated without any notion of enduring time. Our direct experience of time is not of duration but of succession, and I can easily show that a timeless lawful succession leads to the emergence of a well-defined duration effectively identical to Newton's absolute time.

The other half of my ontology comes from quantum mechanics and will be easy for physicists, if not children, to grasp: the wave function defined on a configuration space. I think it is highly relevant for my programme that Schrödinger originally found a *timeless* equation for his wave function. It explains *all* nuclear, atomic, and molecular structures that we find around us. It was even used by Max Born (before Schrödinger proposed an equation that describes evolution of the wave function in Newtonian time) to describe processes regarded as dynamic.

I regard quantum mechanics as a theory that explains structure. Close and open your eyes for a second; you see a structure, a snapshot. What I aim at is a theory that explains the presentation to us of such structures that involves only a timeless comparison of such structures and does not posit *evolutionary* laws and their initial conditions. The fundamental law is a law of structure selection in which structures are favoured by virtue of their structure and nothing else. It is not totally unlike a child selecting the most interesting snapshots among a large collection. To make the connection with experience I propose that awareness is correlated with single snapshots (which can be arbitrarily complex and contain, as it were, snapshots within snapshots). The standard view is that awareness is correlated with a succession of snapshots, which I replace by my 'snapshots-within-snapshots' snapshots. This idea is beautifully illustrated in the film about my ideas shown on Dutch television, *Killing Time*.[27]

Perhaps it will help if I say that Newtonian theory (and even Einstein's theories to a large degree) is like a law that forces an object to follow a path at a definite speed through a landscape once it is set going at some point in the landscape with a definite direction and speed; this is the initial condition, without which nothing can be done with the law. It is easy to show that the speed part of this initial condition is redundant if one considers the whole universe. History is then not a path traversed as some speed but merely a path. The huge change introduced by quantum mechanics is that the notion of a definite path is eliminated and replaced by the wave function that 'samples', or 'looks at', all possible points in the landscape. This can be done in a timeless fashion that is precisely analogous to the way that quantum mechanics determines atomic and molecular structures.

C: While it's of course impossible to predict the eventual social and cultural ramifications of any scientific revolution, I wonder if you have anything to say about the possible consequences which the notion of 'the end of time' might bring about were it ultimately to become as widely accepted as the idea that the earth revolves around the sun is for us today?

JB: That is impossible to answer. All I can say is that life could be less hectic and more contemplative. People in the parts of Platonia where my theory is accepted should cherish the Now more than in this overworked region. To go back to what I said about theology: In the Middle Ages busy kings still spent hours in daily prayer because they believed deeply in eternity and its primary importance. Today, many would reject their beliefs. However, mathematicians have rational grounds for believing in eternal mathematical truths. Theoretical physics has a definite tendency to go in the same direction – on rational grounds. Indeed, it can hardly avoid doing so, since it uses mathematics, and mathematics that is only occasionally true is not much use.

C: You have already mentioned Leibniz a few times, and at the outset of *The End of Time* you describe your 'central idea' as being inspired by the Leibnizian idea that the world is to be understood 'not in the dualistic terms of atoms (one kind of thing) that move in the framework and container of space and time (another quite different kind of thing), but in terms of more fundamental entities that fuse space and matter into the single notion of a possible arrangement, or configuration, of the entire universe'.[28] According to this Leibnizian notion, 'the world does not consist of infinitely many essentially identical things – atoms moving in space – but is in reality a collection of infinitely many things, each constructed according to a common principle yet all different from one another. Space and time emerge from the way in which these ultimate entities mirror each other'.[29] This is an idea which, you suggest 'has the potential to turn physics inside out – to make the interestingly structured appear probable rather than improbable'.[30]

One might be surprised to see a contemporary theoretical physicist drawing so explicitly upon early eighteenth-century rationalist metaphysics in order to rethink the foundations of contemporary physics in this way. However, far from being a mere eccentricity on your part, your application of Leibnizian ideas to fundamental physics and cosmology have exercised a considerable influence upon leading contemporary physicists and cosmologists. Lee Smolin, for example, to whom you introduced Leibnizian and Machian ideas when he was visiting Oxford in 1980, and with whom you subsequently collaborated in an attempting to formulate Leibnizian monadological ideas in precise mathematical form, has gone on to develop, along with Carlo Rovelli and

29. *The End of Time*, op. cit., 240.

30. Ibid.

others, relational theories of quantum gravity and quantum cosmology which are today regarded as the principal rivals to string theory. In this way, in the form of Loop Quantum Gravity and Relational Quantum Mechanics, ideas of distinctly Leibnizian inspiration stand at the very cutting-edge of contemporary theoretical physics. Could you say something about how you came to realise the great potential for the application of Leibnizian metaphysics to contemporary physics, how your interpretation of Leibnizian ideas relates to your central notion of 'Platonia' as 'the relative configuration space of the universe', and about the key differences between your approach to quantum gravity and quantum cosmology and those of Smolin and Rovelli?

JB: In fact, most of my key ideas were developed and presented in my first paper in *Nature* in 1974 before I read any of Leibniz's writings, which happened in 1976-77. My long journey of conceptual exploration began in 1963 with the chance reading of a newspaper article about Dirac's attempts to quantize gravity. This led me to ask myself seriously: What is time? Soon after that I read Mach's great *Mechanics* and this led me to add the question: What is motion? By 1972 I had worked out the framework of a Machian theory of time and motion in classical physics. This has since been elaborated but not fundamentally changed. The notion of relative configuration space (RCS) of the universe that I published in 1974 is Platonia. What I found exciting in Leibniz was a deeper intellectual underpinning of my scheme. Above all, Leibniz insisted that real things must have distinguishing attributes, which was not the case for Newton's identical points of space.

What underlies Leibniz's ontology is the conviction that there is no reality without variety. Indeed, reality *is* variety. Leibniz also has this wonderful conjecture that the actually realized universe is more varied than any other conceivable universe. Stimulated by my enthusiasm for Leibniz, Lee Smolin managed to find a way to express this idea mathematically and we together developed a theory of Maximal Variety.[31] I do think it manages to capture the kind of scheme for which Leibniz was striving. It has generated a fair amount of interest, but as of now does not seem to have any obvious applications in physics.

As regards differences between my approach to quantum gravity and the present approach of Smolin and Rovelli, they concern the antithesis of the discrete and the continuous. When Lee met me, he was already convinced that at the deep microscopic level space must be discrete. As I recall, he had come to this view from his early exposure to the problems of infinities in quantum field theory, which he felt could only be cured by an underlying discrete theory. This was a formative experience to which I had not been exposed. I was initially sympathetic to the idea that the continuum of experience should emerge from a discrete foundation, but rather soon came to the conclusion that the problems to be overcome were great and probably insurmountable. In this respect, Lee and I continue to differ, but we are each inspired by relational examples drawn from Leibniz: a discrete genealogical tree in Lee's case, the continuous distances between bodies (as discussed by Leibniz in the Leibniz–Clarke Correspondence) in my case.

C: In *The End of Time* you admitted that the idea that time does not exist is still 'only a prospect on the horizon', albeit one which might well ultimately turn out to comprise the next great revolution in our understanding of the universe.[32] Since the publication of your book almost a decade ago, 'the small but growing number of physicists' who 'have begun to take the idea that time truly does not exist'[33] seems to have increased considerably. There seems to be a general feeling abroad amongst those searching for that veritable Holy Grail of contemporary physics – that is, a workable theory of quantum gravity – that something fundamental is missing, a common erroneous assumption which needs to be rooted out, and that this erroneous assumption very likely concerns the nature of time.[34] Carlo Rovelli has compared the situation which has existed in fundamental physics over the past century to the 150-year period between Copernicus and Newton – that is, a period of an 'unfinished revolution' – predicting that the next great synthesis, this time bringing together general relativity and quantum mechanics, will require us to learn how to think of the world 'in completely nontemporal terms'.[35] Similarly, Lee Smolin has suggested that the problem of time in quantum cosmology forces one 'to confront the possibility that time and change are illusions', and that we may ultimately 'have to come to terms with a world which, at the most fundamental level, must be described in a language in that includes no words for time'.[36] And indeed even the most aggressive champions of string theory seem now to have come round to the idea – an idea which you have been insisting upon for decades – that any feasible theory of quantum gravity will have to be formulated in background-independent terms[37] and that this might well require the complete elimination of the notion of space and time as a basis for our description of reality.[38] In light of this, are you now more optimistic than you were ten years ago that something like the picture you have developed over the past four and a half decades will ultimately triumph? How do you envisage the next fifty years of development in fundamental physics panning out, and what do you expect to be the chief obstacles in the way of completing the ‘unfinished revolution’ of the past century?

[38] Thus David Gross, described by Smolin as 'one of the most aggressive and formidable champions of string theory' (*The Trouble With Physics*, op. cit., xv), in a recent interview: 'In string theory I think we're in sort of a pre-revolutionary stage [...] we still haven't made a very radical break with conventional physics. We've replaced particles with strings – that in a sense is the most revolutionary aspect of the theory. But all of the other concepts of physics have been left untouched [...] at some point, a much more drastic revolution or discontinuity in our system of beliefs will be required. And this revolution will likely change the way we think about space and time, maybe even eliminate them completely as a basis for our description of reality – that is, leave us regarding them rather as emergent approximate concepts that are useful under certain circumstances. That is an extraordinarily difficult change to imagine, especially if we somehow change what we mean by time, and is probably one of the reasons why we're still so far from a true understanding of what string theory is. [...] Something is missing that is most likely not just another technical development, another improvement here or there, but something that truly breaks with the past. And all the indications are that it has to do with the nature of space and time.' (David Gross, 'Viewpoints on String Theory', at http://www.pbs.org/wgbh/nova/elegant/view-gross.html).

JB: It is certainly encouraging that more and more people seem to be taking my ideas seriously. I am currently in the process of writing up everything I have learned in a monograph with the provisional title *Mach’s Principle, General Relativity, and Gauge Theory*. Thanks to a generous grant from the Foundational Questions Institute,[39] I am now able to collaborate with more young researchers. However, I am not too optimistic that the Holy Grail will be grasped in my lifetime. I suspect that the main difficulty may well be technical complexity or absence of experimental data that can act as a useful guide. However, major conceptual developments are also probably needed. I see two places where conceptual breakthroughs might occur. One concerns the role of complex numbers in quantum gravity. In the quantum mechanics discovered in the 1920s, they entered through the time-dependent Schrödinger equation; it is a fundamentally complex equation. However, there is neither time nor the imaginary *i* in the Wheeler–DeWitt equation, which founds quantum gravity. Numerous papers have proposed essentially the same way to get the *i* back into laboratory physics but I believe that they are all seriously flawed. The other possibility is the one that I already mentioned relating to the failure of general relativity to be scale invariant, so that size is absolute.

C: In his recent book *The Trouble With Physics*, Smolin argues that the lack of progress in physics over the past three decades – in stark contrast to the preceding two hundred years of explosive growth in the field – can in large part be attributed to a certain style of doing science which, while it was well-suited to the problems which physics faced in the middle part of the twentieth century, is ill-suited to the kinds of problems it faces now. Smolin characterises this style as 'pragmatic and hard-nosed', favouring 'virtuosity in calculating over reflection on hard conceptual problems' and contrasts this with the profoundly different way in which Einstein, Bohr, Heisenberg, Schrödinger and the other early-twentieth-century revolutionaries did science, whose work 'arose from deep thought on the most basic questions surrounding space, time, and matter' and who saw themselves as 'part of a broader philosophical tradition, in which they were at home'.[40]

These are sentiments which would certainly have been endorsed by Mach, who put Newton's inability to recognise the equivalence of all inertial frames down to the fact that he lived in 'an age deficient in epistemological critique'[41] and who was the first occupant of the first academic chair explicitly devoted to the philosophy of science. Einstein himself would likewise often extol the virtues of a background in critical epistemology and the history and philosophy of science as providing 'that independence from prejudices of his generation from which most scientists are suffering', holding this 'independence created by philosophical insight' to be 'the mark of distinction between a mere artisan or specialist and a real seeker after truth'.[42] While letting the philosopher do the philosophizing 'might be the right thing to do when the physicist believes he has at his disposal a rigid system of fundamental concepts and fundamental laws which are so well established that waves of doubt can not reach them [...] it can not be right at a time when the very foundations of physics itself have become problematic'. At such times, insisted Einstein, 'the physicist cannot simply surrender to the philosopher the critical contemplation of the theoretical foundations; for, he himself knows best, and feels more surely where the shoe pinches. In looking for a new foundation, he must try to make clear in his own mind just how far the concepts which he uses are justified, and are necessities.'[43]

[40] *The Trouble With Physics*, op. cit., xxii-xxiii.

[41] *The Science of Mechanics*, op. cit., 571.

In your own intellectual formation, was it your extensive background in the history and epistemology of physics that enabled you, unlike the vast majority of your contemporaries in theoretical physics, to break genuinely new ground? Like yourself, Mach and Poincaré were not only physicists, but also distinguished historians of science, who drew upon the full extent of that history in order to develop their epistemological insights. To what extent do you agree with Smolin and Einstein that the cultivation of such a deep philosophical and historical background is necessary in periods of scientific revolution?

---

[42] Quoted in Don Howard, 'Einstein as a Philosopher of Science', *Physics Today* 58 (12), 2005: 34-40.

[43] Ibid.

JB: In the present period, I am sure that Lee and Einstein are right. I love Einstein's comment that, in crisis periods, the task of philosophizing must fall to the physicist, who feels 'where the shoe pinches'. That is surely correct. In my experience, the philosophers tend to try to clarify existing concepts, often ones that the physicists introduced quite some time ago. But the history of science shows that virtually all great breakthroughs have been made by researchers working intensively at the cutting edge. Mostly they can work within an existing paradigm, but at crisis points that fails them. In this case, something new must be tried. It is always the case that revolutions retain much of the old framework and replace parts that have become suspect with genuinely new proposals. In such circumstances a thorough knowledge of the historical development is a huge help.

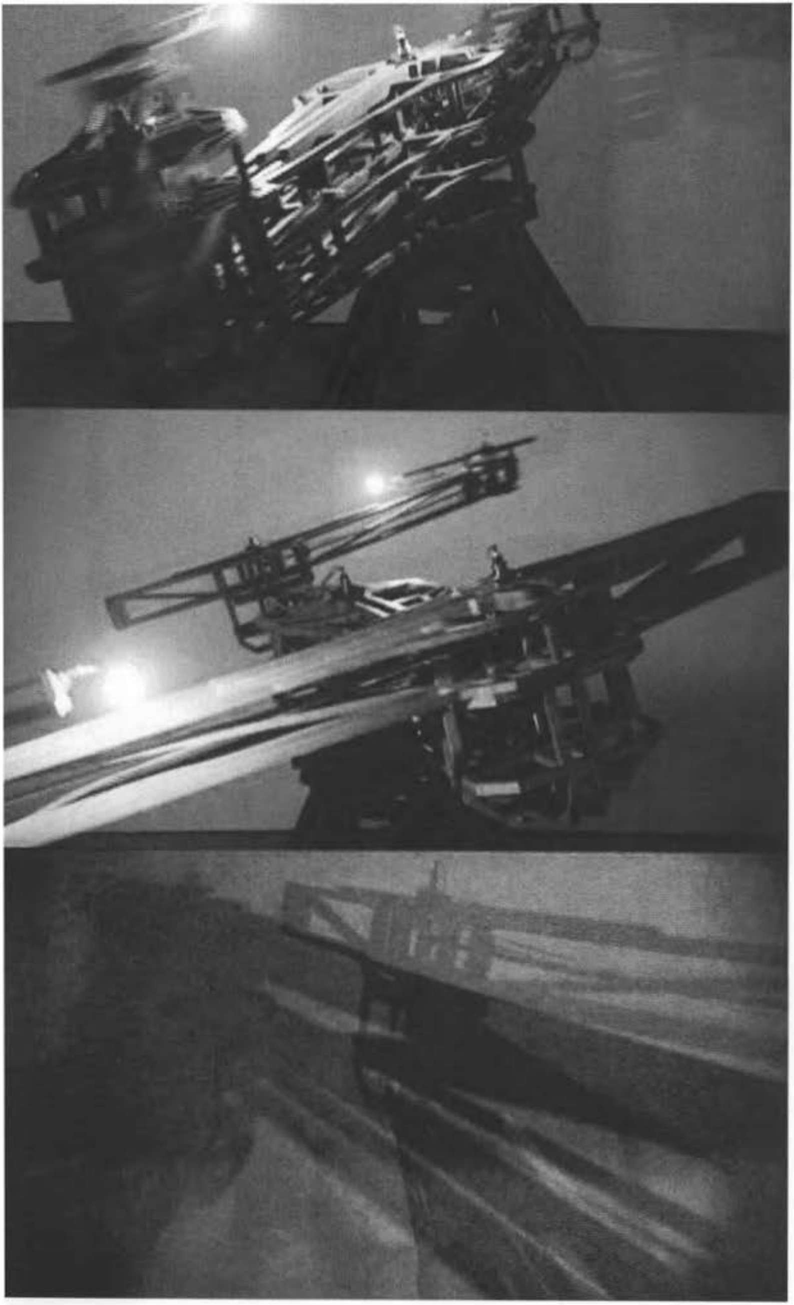
One sees this especially clearly in the discovery by Kepler of his first two laws of planetary motion; it has been a major inspiration for me. Kepler knew the great work of Hipparchos and Ptolemy intimately, but could see that Copernicus's daring proposal to put the earth in motion forced us 'to philosophize about these things differently'. Kepler combined the new and the old in his struggle to explain the wonderful observational data that Tycho Brahe had made. Brahe's 'destruction' of the crystal spheres previously believed to carry the planets make an immense impression on Kepler and prompted him to a remark that is very apposite in the present search for a background-independent formulation of quantum gravity. He said: 'From now on the planets must find their way through the void like the birds through the air'. Einstein's abolition of absolute space and time puts us in a similar position. I like to put it this way: We must understand how the universe can 'swim in nothing'. It is perhaps here that I may be able to make a useful contribution to current research, in which it has become a commonplace to say that quantum gravity must be 'background-independent' because general relativity has that property. What I think is not adequately appreciated is the precise dynamical structure that does make general relativity background-independent. People do not check out the detailed way in which the theory 'swims in nothing'. Nearly all of my work has been devoted to that project.

C: Do you think that you would have been able to make the kind of profound contribution you have made to the foundations of physics had you, all those years ago, and like just about every other theoretical physicist, taken a position in an academic physics department?

JB: I think I definitely made the right decision to stay out of academia. Every now and then, young researchers do ask me for advice about the possibility of going independent. I emphasize that I was lucky but also that I did make one key decision correctly: to earn my living by a well-paid but boring job (translating). This ensured that I never got hooked by the money-earning job and was always longing to get back to the physics. But the most important thing in my case was simply a gift of fortune: the joint problems of time and motion 'took hold of me'. I could never stop thinking about them and little by little accumulated results and insights that to me at least seem to have promise. If young researchers do not have such a burning desire within them, they probably will not succeed either inside or outside academia.

C: Finally, what advice might you offer to young theoretical physicists and philosophers of science today embarking on the dauntless task of perhaps some day helping to bring to a close the 'unfinished revolution' of twentieth-century physics?

JB: I would say that there is an urgent need for clear independent thinking. Both 'clear' and 'independent' are vital. Far too many papers that are published today by young researchers desperate to build up a long publication list that will look impressive on a CV (and ensure at least short listing in a more or less automated process) lack clarity and take important things on trust just because leaders in the field have made certain pronouncements. Several PhD students I know were given computational problems in string theory and told not to ask why they should be done. I am glad to say that two at least promptly got out of the field in protest. I am not saying that string theory is wrong, only that such practice does not advance science. I do feel very sorry for young researchers struggling with today's conditions – but then perhaps it has always been like that. Only those with deep inner conviction and application have ever made it through to great discoveries.



Shadows of Copernicanism

Conrad Shawcross and Robin Mackay

For the best part of five centuries the Copernican revolution has served as a virtually inexhaustible source of philosophical and existential disquiet. Undoubtedly, we have yet to fully adjust our spontaneous image of reality to accord with our displacement from its centre. Yet Copernicus and Kepler retained the Sun as the unique centre. If later developments showed the Sun to be only one of trillions of stars, recent observations even show that singular stars are the exception rather than the rule: The unicity of our Sun is mere cosmic happenstance, in a universe where binary star systems are more common, many capable of supporting Earth-like planets.[1] Considering the overwhelmingly heliotropic tendency of the philosophical imaginary, from Plato to Heidegger,[2] how might our image of thought be disrupted by the loss of the unicity of the Sun, of the object's shadow, of tomorrow's sunrise ...? These are some of the questions posed by Conrad Shawcross's motion sculpture *Binary Star* (2006), a faithful cosmological model whose two 'suns' rise on a world in which there is 'No Such Thing as One'.[3] As the massive, wooden beams of the mechanical contraption rotate in their simulated gravitational dance, its two light sources, in their complex paths, cast double shadows whose shifting superpositions are baffling and unfathomable to the eye.

---

[1] E.V. Quintana & J.J. Lissauer, 'Terrestrial Planet Formation in Binary Star Systems', 2007, at http://arxiv.org/abs/0705.3444v1.

[2] 'Insofar as it structures the metaphorical space of philosophy, the Sun represents what is natural in philosophical language [...] There is only one Sun in the system [...] the unique, irreplaceable, natural referent, around which everything must turn, toward which everything must turn' – J. Derrida, 'White Mythology', in *Margins of Philosophy* (Evanston, IL: Northwestern University Press, 1988), 243, 251.

Philosophical tradition has often metaphorically anchored thought to apparently fixed and permanent characteristics of the physical world. Such models are inevitably burdened with an inability to absolve themselves of their metaphorical investment in the very reality they claim to conceptually underwrite. When we select features from a contemporary image of reality to stand for the task of thought, we always run the risk of becoming a hostage to the fortunes of scientific inquiry, whose progress seems eventually to disabuse us of every illusion of fixity and permanence. In Shawcross's work the physical realisation of such emblematic epistemological models exacerbates the problem of this 'bleeding' of the empirical into the philosophical. Through an intriguing lateral shift, *Binary Star* demonstrates how the epistemological trope of 'Copernicanism', in its naïve acceptation as a simple reversal of perspective between two heavenly bodies, remains tied to 'terrestrial' tropes of thought: above all, the notion that an orbiting multiplicity always pays homage to a central unity. It seems that, even confronted by a radical shift in thinking, we always risk attaching importance to the deepseated

---

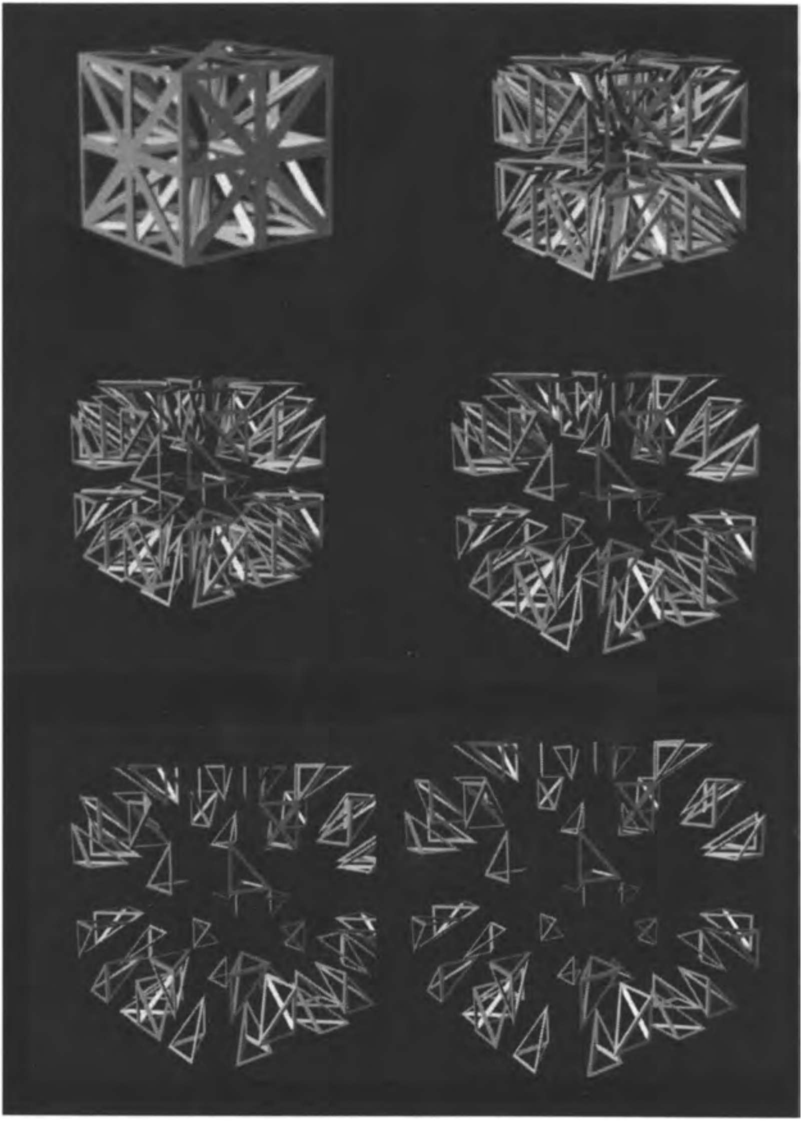
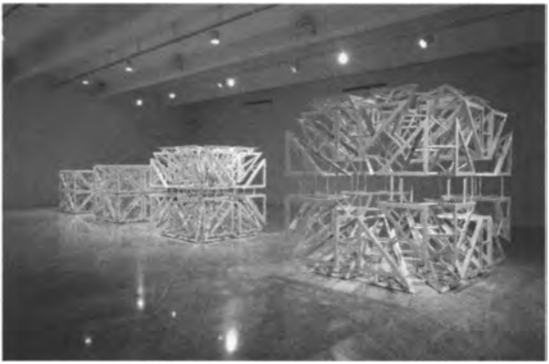
Binary Star (2006)



Schematic of *Lattice Cube Sequence* (2008) prejudices it foregrounds but leaves intact, rather than to its real consequences.

Does philosophy's thirst for such precarious models of thought indicate that a surreptitious exploitation of the all-too-human world is a veritable *condition* for philosophical discourse – at least insofar as the latter seeks to preserve its proper domain from purely mathematico-scientific accounts of reality? The more profound epistemological lesson to be drawn from Copernicanism, of course, is not that of a simple role-reversal. It is that of a gap opened up between a mathematical model freed from the contingencies of human visibility, and the efforts of intuition and imagination – conditioned by those very contingencies – to 'make sense' of such absolutes. Much of Shawcross's work seeks to locate the thinking of the artist and of the philosopher on this fractured terrain, and to inquire after the compromise involved.

In recent work, the artist confronts mathematical models of space with those of an art movement that defined itself in terms of conceptual interrogation. Artists such as Sol Lewitt and Donald Judd, pioneering a research programme into space as the fundamental element of artistic practice, selected the cube as a kind of fundamental particle of aesthetic experience; representing, apparently in the most elementary manner, the three-dimensional Cartesian grid, the plastic degree-zero which these artists would seek to organise in optimally simple and modular fashion. In Shawcross's *Lattice Cube Sequence* (2008) a 'barycentric subdivision' (the cube is sliced by planes connecting the 'barycenters' which divide each of its faces into two) allows the cube to retain maximal simplicity and symmetry, whilst breaking it down into a set of tetrahedrons. With this mathematical procedure of simplification into more basic constituent entities – the same 'simplicial approximation' used to build up from simple forms the complex computer graphics models used in movies – Shawcross questions the claim of Lewitt's 1960s cubes to be the fundamental 'simplex' of three dimensional space ('Space [...] thought of as [...] cubic area'),[4] and reconsiders the nature of a conceptual art practice that avowedly 'doesn't really have much to do with mathematics, philosophy, or any other mental discipline'.[5]



Lattice Cube Sequence (2008)

What Shawcross explodes here is the bond between aesthetic elegance and conceptual simplicity which the sixties conceptualists had tried to push to the limit. He has often tested this fundamental unity of human aesthetic perception and mathematical elegance, confirming it, for instance, in his *Loop System Quintet* (2006), a mechanised visualisation of musical harmony. But contemporary science yields substructures of 'basic elements' whose configuration cedes nothing to our spontaneous image of the world, unbinding us from the Greek heritage of mathematico-aesthetic intuitions (Pythagorean harmony, Platonic solids ...). Tracking this 'Copernican' vector, *Lattice Cube Sequence* sees the serene perpendicularity of the cube giving way to an inner structure whose complexity renders it opaque to the eye. As the simplices explode outward, the form of the cube itself evaporates, and with it the cubic grid system, as if it had never been more than an optical illusion, an anthropological artifact. The rotational 'grammar' of the cube, of which Lewitt was the virtuoso, seems in retrospect a parochial dialect.

---

[4] S. Lewitt, *Sol Lewitt* (NY: Museum of Modern Art, 1978), 167.

[5] Ibid., 166.

It would be wrong to imply that Lewitt himself was unconscious of his 'failure' in this respect: Against any theoretical or illustrative relation to science, he argued forthrightly for the artist's need to be 'smart enough to be dumb'.[6] And his intention, for instance, for the very first modular cube 'to be large, but not too large',[7] clearly betrays the anthropocentric nature of his research programme. In this respect Shawcross's piece is as much homage as critique, since the very manufacturing and exhibiting of *Sequence* opens it to the vagaries of embodied perception. In inviting the emotions and associations occasioned by its physical encounter to derail the precision of the scientific model, *Sequence* seems designed as much to disturb as to evoke the self-sufficient serenity of its abstruse prototype.

---

[6] S. Lewitt (quoted by L. R. Lippard) in Lewitt, op.cit.

[7] Ibid., 4.

Shawcross's work is characterised by this ambivalence towards its scientific sources. Against the violence done to the imagination by mathematical science, the deliberate, relentless arcs of *Binary Star*'s hefty oaken beams sing the glory of the creative vigour of the mad inventor, the gentleman-amateur. With scientists' models of reality increasingly inimical to any grounding in metaphors drawn from the everyday lifeworld, Shawcross's diligent physical renderings mimic the efforts that philosophy must make to incorporate them into the grain of language without ceding the latter entirely to mathematical abstraction. The artist himself has consequently qualified his machines as 'tragic' or 'misguided'; but the most profound content of the work seems to lie precisely in the vacillation between object and model that indexes its 'failure'.

From the same group of work as *Lattice Cube Sequence*, *Slow Arc Inside a Cube* (2007) redeploys the mechanism of *Binary Star* at a more abstract level. The 'slow arc' is described by a brilliant, omnidirectional halogen bulb moving inside a cube whose barred walls it projects onto the walls of the installation space, in a ceaselessly shifting mapping of object onto environment. Rather than a separate source of light illuminating worldly objects and casting shadows, the blinding core of the object brands the environment with the continuous phases of its own projected image.

Shorn of *Binary Star*'s literal reference to astronomical Copernicanism, *Slow Arc* exerts all the more profound pressure on philosophical (Kantian) Copernicanism, for which the transcendental ego has become the point-source of objectivity. Its proposed object-model scrambles the Platonic heritage of Kantianism, and releases a cloud of philosophical associations. In transforming the environment into a continuously-shifting image, *Slow Arc* already seems to move through Husserlian phenomenology towards Gabriel Catren's quantum model of objecthood. In Catren's account, the unification of multiple phenomenal aspects into a single object ('eidetic variation') is no longer the work of a synthesising subject. Instead, the object itself is 'a kind of "projector" of phases, aspects or profiles', a hallucinatory 'dream machine' with its own inner Sun.[8]

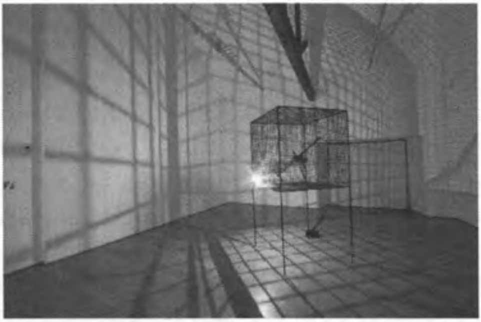
For Shawcross, *Slow Arc* bears a broader reference to the process of scientific experimentation and discovery. The piece was directly inspired by x-ray crystallographer Dorothy Hodgkin's discovery of the molecular structure of insulin, and in particular by the scientist's comparison of the exhaustive process of extrapolating the dense protein 'cloud' from reams of chromatographic grids with 'trying to work out the structure of a tree purely from looking at its shadow'. Like Plato's Sun, the blinding core of the object cannot be confronted directly, but must be speculatively inferred as the origin of the projections thrown onto the inner surface of a phenomenal *camera obscura.*

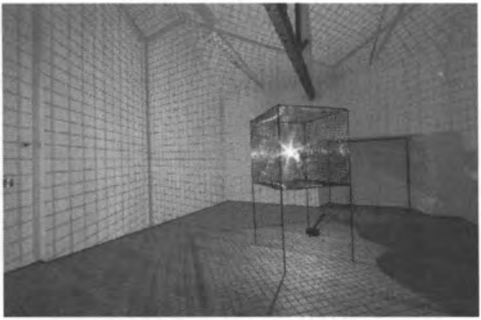
Finally, however, the source of light itself is a moving target. It is the cage – that through which the light is thrown to create the shifting projections – that is the only constant. So an alternative interpretation might take up Alberto Gualandi's post-Copernican anthropocentrism:[9]

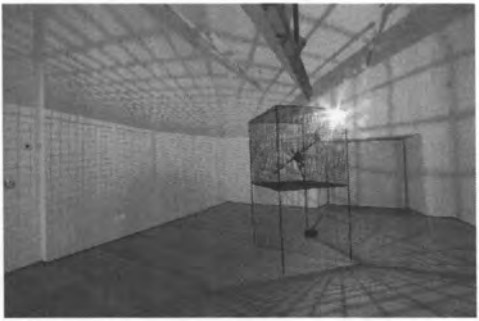
---

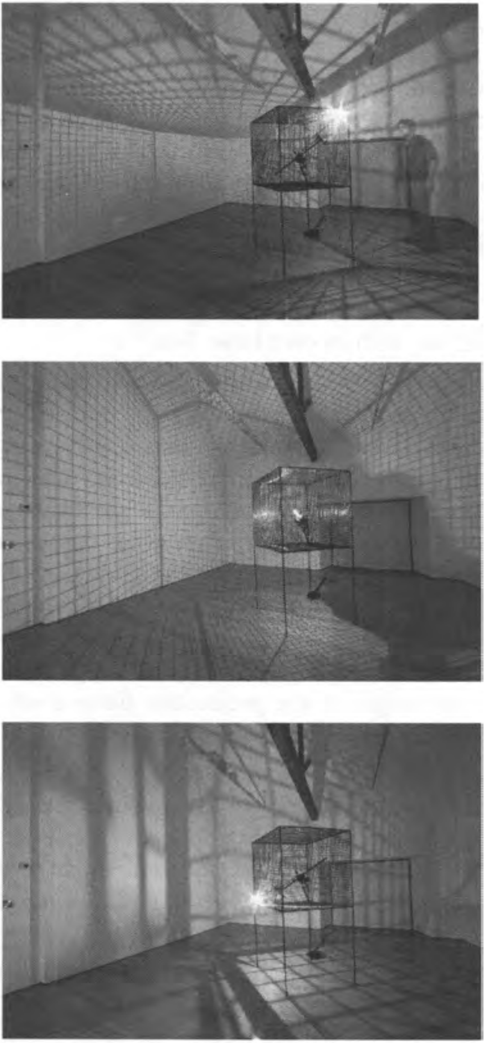
[8] See G. Catren 'A Throw of the Quantum Dice Will Never Abolish the Copernican Revolution', this volume.

[9] See A. Gualandi, 'French Philosophies of Nature and the Overturning of the Copernican Revolution', this volume.







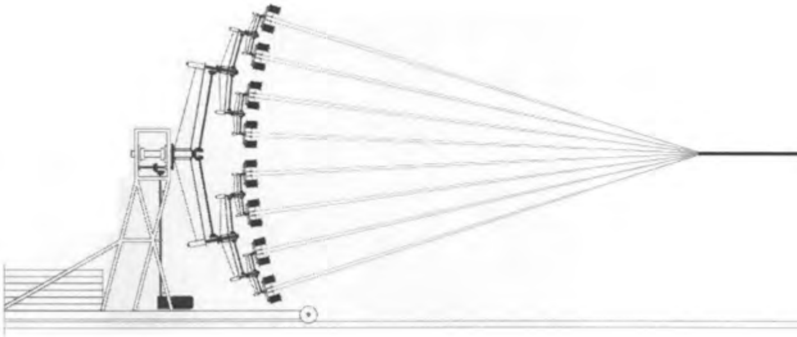


Slow Arc Inside a Cube (2007)

The structure that locks us out of the object's core, imprisoning us in the phenomenal realm, is also the only constant by which we can measure that which exceeds it.

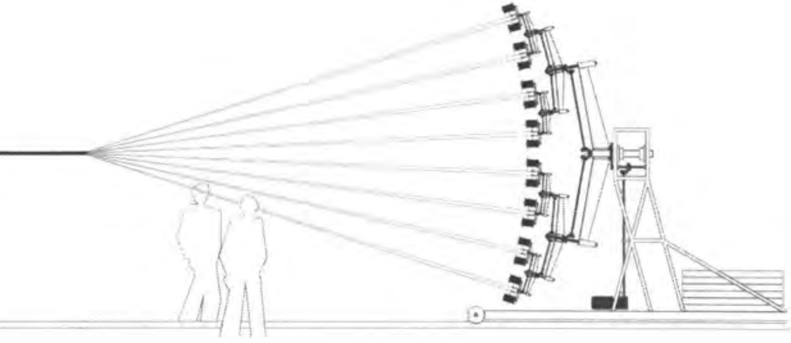
In this case, both artists and philosophers should be wary of falling victim to another superficial reading of the 'Copernican imperative', indicating a peremptory jettisoning of the evidence of the senses and of inherited language. 'Smart enough to be dumb' and 'misguided', a part of their task will consist instead in probing the discontinuities and the slippages between those blinding mathematical abstractions forever closed to intuition, the shadows they cast in experience, and the imaginary heritage with which we struggle to make sense of them.

Fittingly for what has been read here as an extended meditation on philosophical heliotropism, Shawcross's latest 'irrational machine', to be unveiled in summer 2009, returns to the depths of the Earth. But *Chord* does



Working sketch for *Chord* (2009)

not presume, like the philosopher, to drag benighted cave-dwellers up into the light; instead it excavates and brings to light a forgotten underground space. A descendent of Shawcross's (2001) spinning-machine *Yarn*, the piece will elaborate on that work's automated weaving of hundreds of coloured threads into a single rope. But in *Chord* this process will be co-ordinated by the two halves of a gigantic 'twin machine' to be installed in London's disused Kingsway tram tunnel. Laying down their own tracks as they proceed, the two machines will illuminate the expanding space between them as their multiply-articulated tri-arms fabricate a line of communication across it. According to Shawcross's latest yarn (narrative, creation myth, epistemological model?), therefore, the emergence of a linear simplicity is contemporaneous with the clearing of the space in which it is knitted together, by intricate machinations on the edge of darkness.



Who's Afraid of Scientism?

Interview with James Ladyman

In 2007 James Ladyman and Don Ross published Every Thing Must Go: Metaphysics Naturalized,[1] *an attempt to synthesize Ladyman's 'Ontic Structural Realism' and Ross's 'Rainforest Realism' into a unified metaphysics applicable to science from physics to economics. Beginning with a blistering polemic against what they call 'neo-scholastic metaphysics', Ladyman and Ross argue for an approach to metaphysics which goes far beyond the vague science-friendliness characteristic of so much of contemporary soi-disant naturalism in favour of an unabashedly 'scientistic' stance. Dispensing with the habitual ontology of 'little things and microbangings' which continues to hold sway in contemporary 'pseudo-naturalist philosophy',* Every Thing Must Go *provides the case for a radically naturalistic metaphysics capable of taking on board the most counterintuitive findings of modern physics without impugning the epistemic credentials of the special sciences. In our interview, Ladyman discusses the reasons for his exasperation with philosophers who persist in doing metaphysics as if modern science had never happened, provides a robust defence of 'the scientistic stance', and explains how the position developed in* Every Thing Must Go *provides a heuristic framework for the unification of the sciences via a dialectical synthesis of the strengths of both realism and empiricism.*

---

[1] James Ladyman and Don Ross with David Spurrett and John Collier, *Every Thing Must Go: Metaphysics Naturalized* (Oxford: Oxford University Press, 2007).

Collapse: You are known within philosophy of science circles for your defence of a form of scientific realism you call 'ontic structural realism'. The list of names of philosophers and physicists who have subscribed to one or another form of structural realism is an impressive one indeed. Restricting ourselves to the twentieth century we have Henri Poincaré, Ernst Cassirer, Bertrand Russell, Arthur Eddington, Moritz Schlick, Rudolf Carnap, Grover Maxwell and, more recently, John Worrall and Elie Zahar. A landmark paper in the current debate was John Worrall's 1989 'Structural Realism: The Best of Both Worlds',[2] in which structural realism is presented as a kind of synthesis of the insights contained in both the (realist) 'no miracles' argument, on the one hand, and the (anti-realist) 'pessimistic meta-induction', on the other. For those who might not be familiar with recent debates concerning scientific realism, could you briefly describe the nature and import of these two arguments, and how they pull in opposing directions?

James Ladyman: The no-miracles argument in its crudest form is the claim that if scientific theories were not correctly describing the nature of the unobservable entities and processes that cause what is observable, then the success of science in describing the phenomena would be completely mysterious, so our best scientific theories do indeed describe the hidden workings of the universe. The argument is made more sophisticated by Richard Boyd and others who refer not just to the success of science, but the success of the highly theory-laden methods used by scientists as one generation of new hypotheses become the background theories deployed to design instruments and experiments in the development of the next generation of theories. The pessimistic meta-induction can already be found in crude form among the arguments of the ancient Greek sceptics; it says that we ought not believe in more than the approximate empirical adequacy of our best scientific theories because there have been highly successful theories in the past that by our current lights are false, and that our best contemporary theories are no different in kind and liable to befall the same fate. (In the modern literature this argument is was forwarded by Poincaré, and then its name was coined by Hilary Putnam. It is usually now associated with Larry Laudan, but he never really puts it quite like this.) Clearly, these arguments are in tension. The first would now have us believe in the quantum electrodynamic field because of the predictive success of the relevant theory, but would have had us believe in the ether because of the success of Fresnel's wave optics; and the second says that the quantum electromagnetic field will go the same way as the ether in the end, so we ought not to believe in such things.

---

[2] *Dialectica* 43 (1-2), 1989: 99-124.

C: In 1998 you published 'What is Structural Realism?',[3] a paper which quickly became the focus of debate. Here you argue that structural realism 'gains no advantage over traditional scientific realism if it is understood as merely an *epistemological refinement* of it, and that instead it ought to be developed as a *metaphysical* position'.[4] As already mentioned, the version of structural realism which you subsequently elaborate you have called 'ontic structural realism' (OSR), though others have preferred the term 'eliminative structural realism'.[5] The more traditional, epistemological variety, in contrast, has come to be referred to as 'epistemic structural realism' (ESR), which you have also called 'Kantian structural realism'. Could you explain the key difference between these two positions, and which considerations led you to the conclusion that structural realism demanded to be reformulated as an ontological or metaphysical rather than a merely epistemological position?

---

[3] *Studies in the History and Philosophy of Science* 29 (3), 1998: 409-28.

[4] Ibid.: 411; emphasis added.

JL: ESR is the claim that our best scientific theories should be thought of as describing the relations among unknown unobservable entities. That is why I have called it 'Kantian structural realism', since it incorporates the view that the intrinsic natures of the unobservable entities are epistemologically beyond reach, i.e., noumenal. Rae Langton's 'Kantian humility', for example, is very similar to ESR.[6] OSR is the claim that the world does not consist of a set of entities with intrinsic natures at all, but rather the world has a relational structure which is described by our best scientific theories. Fundamentally, OSR seeks to deny ontological priority to individual objects, and to upgrade the ontological status of relational structure. Exactly what form OSR should take is a matter of current debate. ESR is an ontologically conservative thesis that proposes a purely epistemological revision of scientific realism – hence the name. OSR is motivated by reflection on quantum mechanics and general relativity, as well as the problem of accommodating theory change in the history of science. I was led to OSR in part by my interest in the ontology of contemporary physics (and Steven French's work on identity and individuality in quantum mechanics),[7] and in part by the thought that the problem of theory change is an ontological one. By this latter claim I mean that the problem is to understand how there can be continuity between theories such as Newtonian mechanics and general relativity, or Maxwell's electromagnetism and quantum electrodynamics. This is an ontological problem because the natures of the entities postulated by the theories are so different. However, there is much continuity in the structure they attribute to the world via their mathematical form.

C: Your 1998 paper contains as an epigram a quotation from Max Planck which reads as follows: '[T]he structure of this physical world consistently moved farther and farther away from the world of sense and lost its former anthropomorphic character [...] Thus the physical world has become progressively more and more abstract; purely formal mathematical operations play a growing part.'[8] The quotation does not receive any discussion in the paper itself. Could you explain why you chose this as an epigram, and what light you think it sheds on the debate over scientific realism?

---

[7] Steven French has also contributed much to the development of OSR. A comprehensive guide to the literature on both OSR and ESR can be found in the entry 'Structural Realism' by James Ladyman in *The Stanford Encyclopaedia of Philosophy*, http://plato.stanford.edu/entries/structural-realism/.

[8] Max Planck, 'The Universe in the Light of Modern Physics' in W. Shirmacher (ed.), *German Essays on Science in the 20th Century* (New York: Continuum, 1996), 38-57; cited by Ladyman, 'What is Structural Realism?', op. cit., 409.

JL: I happened to have a book called *German Essays on Science in the Twentieth Century* and read the Planck paper.[9] At that time I think I was attracted by his claim that mathematics has become more and more central to scientific representation. The quote seemed to encapsulate what I wanted to say in the paper, namely that we should stop trying to interpret physics in terms of objects of some kind and take the mathematics to be describing relational structure directly. When I look back upon it, I'm very glad I chose that epigram since I have more recently come to despair of many philosophers' inability to escape the manifest image, and their insistence on trying to do metaphysics with categories like object and intrinsic property, which I now see as anthropomorphic in the sense that they are a projection of how the everyday world of our experience is conceptualized. Scientists, especially physicists, have moved on, and it is time that metaphysicians tried at least to catch up.

C: Many philosophers will of course strongly protest your suggestion of their 'inability to escape the manifest image', not because they regard themselves as having already escaped it, but rather because they will insist that such an escape is neither possible nor desirable. For many such philosophers, the progressive deanthropomorphisation of the world exhibited by the history of the natural sciences, far from being a cause for celebration, or even for revising our commonsense ontology in accordance with it, is rather something to be fiercely guarded against or 'critically' circumscribed. So long as natural science can be 'kept in its proper place, as a rigorous inquiry internal to the disengaged stance', it does not pose too much of a threat, but to base one's ontological commitments solely on the deliverances of the natural sciences is to be 'uncritical', 'naïve', and 'scientistic'. A crucial part of the philosophers task, on this view, is that of 'stopping natural science from overstepping its proper boundaries' and thereby 'forcing due humility on it'.[10] How would you respond?

---

[9] Ibid.

JL: Escape from the manifest image is clearly possible for science. The scientific image of the physical world is remote from the common sense one. Let me mention just two of many examples that could be given. Firstly, if you walk in bare feet from a carpet onto ceramic tiles, the latter feel cold. According to the manifest image the tiles are colder than the carpet. Science tells us that this is an illusion. The tiles are at the same temperature as the carpet but they are better conductors of heat and so the heat from one's feet is whisked away by them making them feel cold. Secondly, according to the manifest image motion is observable and so we ought to feel it if the Earth was in motion, but according to the Galilean principle of relativity only relative motion is observable.

The manifest image is not itself fixed or necessary but is a product of the contingencies of our evolution, and of course there is some variation in it since the acuity of the senses varies between musicians, artists, surveyors and so on. I see no reason why philosophers should find escape from the manifest image impossible if it is possible for scientists. To those who maintain that science should stay in its proper place I reply that the predictions that science makes are ultimately tested by their observable consequences for the behaviour of things in the manifest image. So it is wrong to suggest that science should not impinge on the manifest image because it just does, as a matter of fact.

---

[10] Mark Sacks, *Objectivity and Insight* (Oxford: Oxford University Press, 2000), 323.

Another couple of examples: Firstly, contrary to what one would expect, when a helium balloon is held by a passenger in the cabin of an airplane as it accelerates down the runway, the balloon will spontaneously move forward in the direction of motion rather than backwards. This is predicted by Einstein's Equivalence Principle, according to which it is impossible to locally tell whether one is accelerating in one direction or subject to a uniform gravitational attraction from the opposite direction. Returning to the example above, Galilean relativity is also a feature of the manifest image since, as Galileo pointed out, insects flying around in the cabin of a steadily moving ship on a calm sea move just as if the ship was at rest and behave no differently, and one is able to sit at a desk and write oblivious to the motion of the vessel. Partial and total solar eclipses or the passage of comets are predicted by science but manifest to all.

Of course, scientific knowledge affects the manifest image profoundly in a way that we must celebrate, by extending people's lives through medical intervention. The scientific understanding of the causes and effects of cholera directly motivates the treatment of continual administration of saline solution which is estimated to have saved around three million lives to date. Philosophers may insist that science should keep out the manifest image but they doubtless write their arguments to this effect on computers, arrange to meet their colleagues to criticize science on mobile phones and so on. Does anyone with a seriously ill child really want science to keep out their manifest image?

I regard all such talk of keeping science in its proper place as the expression of either bad faith (because they can't really mean it when push comes to shove), conservatism (because they want to defend the doctrines of some old religion), or intellectual laziness (because science is vast, complicated and hard to learn). The charge that basing one's ontological commitments on science is naïve and uncritical is ironic in the extreme given that it is likely to be made by people who wish to defend the uncritical acceptance of intuition against the hugely complex and constantly evolving refinements engendered by science. The scientific image is ever subtle and never simple. In the end the epistemic authority of science is based on its astonishing novel predictive success and its role in the development of technologies or extraordinary power. Deference to science in respect of how the world is seems eminently sensible, but that science is supreme does not entail that it should be regarded as perfect or uncritically accepted. Scientific knowledge is provisional, incomplete and approximate. One might think that science is very far from ideal and hence that (to paraphrase the well-known saying) science is the worst source of metaphysical beliefs, apart from all the others.

C: While few philosophers would disagree with you regarding the various ways in which science and technology 'impinge upon' the manifest image, many would nevertheless insist that it simply doesn't follow from this that one ought to let the tail of natural science, as it were, wag the dog of our general worldview. Indeed, many philosophers who insist upon the methodological and ontological priority of the manifest image explicitly foreground the ways in which science and technology have radically transformed the 'everyday life-world' in their critiques of what they call the 'technological' or 'instrumental rationality' of late-capitalist post-industrial society. By privileging natural-scientific knowledge over all other forms of human experience and taking technical-scientific rationality as the paradigm of rationality in general, positivist and naturalist philosophers are accused by such critics of espousing a pernicious ideological conservatism which serves to perpetuate the politico-economic status quo and stifle creative thought.

Similarly, while few philosophers would deny the extraordinary success of science in making novel predictions, in improving the general quality and length of human life, and in providing explanations for the behaviour of observable events, many would insist that none of this obliges one to embrace ontological naturalism. Thus, for example, Edmund Husserl famously argued that the ontological posits of natural science comprise 'nothing more than a garb of ideas thrown over the world of immediate intuition and experience, the life-world',[11] amounting to 'the surreptitious substitution of the mathematically substructed world of idealities for the only real world, the one that is actually given through perception, that is ever experienced and experienceable – our everyday life-world'.[12] Maurice Merleau-Ponty goes even further, claiming not only that '[s]cientific points of view are always both naïve and at the same time dishonest' on account of their refusal to acknowledge the ontological anteriority of the manifest image, but that it ought to be the task of the phenomenologist 'to re-establish a direct and primitive contact with the world [...] that world which *precedes* knowledge, of which knowledge always *speaks*, and in relation to which every scientific schematization is an abstract and derivative sign-language, as is geography in relation to the countryside in which we have learnt beforehand what a forest, a prairie or a river is.'[13]

---

[11] Edmund Husserl, *Experience and Judgment* (Evanston: Northwestern University Press, 1973), 44-5.

Such strongly instrumentalist views of science are by no means restricted to phenomenology, of course, and Husserl's comments have been enthusiastically endorsed by a good number of prominent philosophers in the 'analytic' tradition, including Bas van Fraassen and Hilary Putnam. Thus Putnam, for example, citing the authority of both Husserl and Wittgenstein, argues that since natural science is 'a product of the same interests that underlie our conceptual construction of our *Lebenswelt*' it should no more be considered 'a description of reality "itself" than is our everyday talk of colours or of meanings or of desires or of values or of anything else'.[14]

---

[12] Edmund Husserl, *The Crisis of European Sciences and Transcendental Philosophy* (Evanston: Northwestern University Press, 1970), 48-49.

[13] Maurice Merleau-Ponty, *The Phenomenology of Perception* (London: Routledge, 1962), vii, ix.

[14] Hilary Putnam, *Words and Life* (Cambridge, Mass.: Harvard University Press, 1994), 489.

For all such philosophers, the suggestion that it is possible even for scientists to 'escape the manifest image' would thus amount to failing to take account of the way in which the 'everyday *Lebenswelt*' furnishes the quasi-transcendental 'conditions of possibility' for scientific practice, and that it is only by disavowing the reality of such necessary conditions that it is possible for the scientific realist to reify the 'mathematically substructed world of idealities' of natural science as the only 'real' world. While, as you suggest, such views may indeed often be motivated ultimately by little more than bad faith, conservatism, or what have you, they are undoubtedly widespread in contemporary philosophy, and so if we are to avoid the tiresome spectacle of philosophers slinging *ad hominem* accusations and counter-accusations of 'naïveté' and 'conservativeness' at one another, it would seem that such arguments must be squarely confronted. How, then, would you go about attempting to persuade such philosophers of the erroneousness of their reasoning, or to convince them that they ought instead to embrace what in your recent book you call a 'radically naturalistic metaphysics'?[15]

JL: I see absolutely no evidence for the claim that scientific rationality is ideologically conservative or gives any support to the politico-economic status quo. Of course Lenin was hugely enthusiastic about scientific rationality and empiricism. More recently, note that the enemies of science in the USA are the members of the Christian right, who deny that humans evolved and have highly conservative views about the role of women and the civil rights of homosexual people. Moreover, of course, the existence of human-caused global warming has been advocated for years by independent scientists who have struggled to overcome the opposition of vested interests among the politico-economic elite. Those who are most enamoured of science are often also those who are most critical of prejudices of class, race and gender. On the other hand, cultures that antedate modern science have been capable of slavery and horrendous barbarism.

---

[15] *Every Thing Must Go*, op. cit., 1.

More generally, I am not even sure that there is such a thing as 'the status quo' in the contemporary world, since it seems to be changing rapidly and quite unstable; but technology is ultimately essential to all human life, given that we have been unable to survive without tools for all of our recent evolutionary history. Most people who live outside of industrialized societies are fairly keen to have their life-worlds transformed by science and technology. (For example, while the medicalization of child-birth may have been overdone in some societies, it should not be forgotten that infant and maternal mortality without modern medicine is extremely high.) Of course, lamentably, what usually goes with that transformation is a degree of exploitation, pollution and so on, but the selfish disregard for the wellbeing of others and of the environment is not a product of the Enlightenment.

I once reviewed a book by Mary Midgley in which she claimed that deforestation was in part caused by Cartesian dualism, as if vast reaches of Western Europe had not been deforested by our ancient ancestors. Frankly, I find the easy association that many intellectuals make between bad things about industrial and post-industrial capitalism and scientism in metaphysics completely naïve. The tragedy of the commons, which may well lead to the extinction of many species of fish due to over-fishing, is just a familiar feature of social life writ-large, and if it is prevented it will be because science has identified the problem and because we rationally decide to collectively deal with it. Science and technology certainly amplify the effects of human greed and our tendency to discount the future in favour of making a fast buck today, but the latter traits are perennial features of our species.

I am completely at a loss about who advocates privileging scientific knowledge 'over all other forms of human experience'. This would be like arguing that listening to music is better than walking in the countryside. I don't know of anyone who argues that scientific reasoning is better than the aesthetic appreciation of music or making love. However, if what is being claimed is that scientific knowledge is superior to folk wisdom or whatever, then I think that this is largely true. Science is the best source of knowledge about disease and how to treat it for example, and exorcism simply doesn't do the trick. If we are to respect people's feelings about the nature and causes of disease then presumably we must respect the feelings of religious fundamentalists who believe that homosexuality is a disease. Similarly, should the views of people whose intuitions tell them that people of a particular race are unlike them and not to be trusted be respected because to not do so is to deny the reality of their experience? While the academic critics of scientific rationality may be expecting it to be replaced by some kind of new age spirituality that will re-enchant nature, de-alienate us and inaugurate some kind of postmodern arcadia, the actual alternatives to science are the ideologies of bigotry and superstition.

As for stifling creative thought, again I see no evidence that taking science to be our best source of knowledge about how things are does this. Nobody is suggesting that artists and musicians must learn scientific theories and use them as sources of inspiration. Lived human experience and the study of great art fuels the imagination and creativity, and will do so regardless of the source from which the individual acquires their metaphysical beliefs. Science is continually renewed by human creativity and in no way conflicts with it. You mention the engaged stance, and here I agree that scientific rationality cannot tell us upon what values to base our lives. However, I am not suggesting it should, just that it be our guide with respect to our metaphysics. Furthermore, let me repeat that as a guide it should be considered to be fallible and liable to revision.

The quote from Husserl is very interesting and makes a very different point from the one about ideological conservativism. In a sense I agree with him that the mathematical idealities are all we have to substitute in metaphysics for the manifest image, since the scientific picture of the world is painted with mathematics. However, I do not think the everyday world is fixed and independent of theory. Note also that it is susceptible to appearances that must be challenged independently of science, for example, mirages and other illusions. Even in the manifest image, a rainbow will be seen to be an illusion since it looks to be in different places to different people. So from my perspective, we have either the manifest image, which we have good reason to believe is full of illusion and not our best picture of the nature of reality, or we have the scientific image. I have plenty of time for philosophers like van Fraassen who say we must embrace agnosticism about all matters metaphysical. However, it is important to note that van Fraassen does not advocate some kind of non-scientific metaphysics but rather recommends not doing metaphysics at all. Again, there is no connection between van Fraassen's and Husserl's claims on the one hand, and the ideological critique of scientific rationality on the other.

I do not think what Merleau-Ponty says about dishonesty is correct, since it is perfectly possible to acknowledge that our experience of the world is the ultimate source of all scientific knowledge while retaining a scientific outlook. Furthermore, to say that our experience is *epistemologically* prior is not to say that it is *ontologically* prior. If by the latter he means to deny that there was lots of stuff going on in the world prior to humans arriving on the scene then I see no reason to believe that. On the contrary, it is the idea that we might restore some mythical purely 'direct and primitive contact with the world' that is naïve. Babies perhaps have it, but they spend their time using their contact with the world to make their subsequent contact with it less direct and primitive, and for good reason since the world unconceptualized is much less forgiving to those seeking to survive in it. Of course, there is always an element of direct and primitive contact with the world in our experience, particularly noticeable through intense sensation perhaps. But then it can hardly be the job of the philosopher to restore this in us since it is always present. Anyone who feels a deficit of direct contact with the world is best advised to go for a good walk, as their ailment is not liable to be cured by reading phenomenology.

Against Putnam I argue that the whole point about the scientific image is that it is what you get when you collectively refine the *Lebenswelt* in the light of theoretical reasoning and vast ranges and quantities of empirical data, so of course it is a better description than that with which we started. On the other hand, it would be a fool who argued that the manifest image is not part of the real world. The fact of our experience is itself an empirical phenomenon and, whether or not science can explain it, it would be absurd to deny its reality.

C: You have recently published *Every Thing Must Go: Metaphysics Naturalized*, co-authored with Don Ross and containing contributions from David Spurrett and John Collier.[16] While the first part of the book's title expresses your eliminativism with regard to individual objects – that is, your ontic structural realism (OSR), mentioned above – the second announces a project for a metaphysics that would, as you put it, 'escape from the manifest image'. Such a 'radically naturalistic metaphysics' is 'motivated exclusively by attempts to unify hypotheses and theories that are taken seriously by contemporary science', and you argue that 'no alternative kind of metaphysics can be regarded as a legitimate part of our collective attempt to model the structure of objective reality'.[17]

Given all this, one might be somewhat surprised to hear you say that you 'have plenty of time for philosophers like van Fraassen who say we must embrace agnosticism about all matters metaphysical'. As far as we understand it, van Fraassen's advocacy of agnosticism regarding metaphysics is to a significant extent motivated by his concern to delimit the scope of what he calls the 'Copernican spirit' or 'objectifying inquiry' characteristic of science in order to make the world safe for the cognitive aspirations of 'non-objectifying' modes of discourse, those of religion in particular.[18] Like many philosophers over the past few centuries, one of van Fraassen's driving concerns is that if we take the scientific world picture to be 'our entire world picture' then 'we ourselves don't seem to fit into our own world picture'[19] – in other words, that there seems to be little room to accommodate our conception of ourselves as *persons* (this being of special concern for van Fraassen 'because that topic covers the, for religion, all-important subject of personal encounter with the divine').[20]

---

[16] *Every Thing Must Go*, op. cit.

[17] Ibid., 2.

But whether or not the motivating concern is the explicitly fideistic one of safeguarding religion from the supposed perils of a 'materialist worldview', the idea that it is either possible or desirable to base one's entire *Weltanschauung* on the deliverances of the sciences is one which has always been strongly resisted by the vast majority of philosophers, and is nowadays often blithely dismissed with little more than an invocation of the (pejoratively-intended) term 'scientism'. However, while you are happy to assume the latter epithet, you argue that the explicitly 'scientistic stance' you advocate does not 'impugn the everyday status of objects like tables and baseballs',[21] nor does it entail a narrowly physicalist world-picture suited only for those who share a Quinean 'taste for desert landscapes' (what van Fraassen disparagingly calls 'the spiritually anemic tastes of scientism').[22] While what you call 'fundamental physics' retains an irreducible position of ontological priority inasmuch it is taken to impose definite asymmetrical constraints upon the permissible ontological commitments of the special sciences, your project of unification, guided as it is by the idea of consilience rather than reduction, results in an ontology 'of lush and leafy spaces rather than deserts' for which Don Ross coined the term 'Rainforest Realism'.[23]

---

[18] See Bas van Fraassen, *The Empirical Stance* (Yale University Press, 2002), esp. 153ff.

[19] Ibid., 189.

[20] Ibid., 190.

Obviously, this is not a simple thing to explain in a few words, but could you say something about how you reconcile your physics-motivated eliminativism with regard to individual objects with an ontology which neither impugns the everyday status of objects nor has recourse to any notion of 'emergence'?

JL: The reason why I have time for van Fraassen's agnosticism about the metaphysical content of scientific theories is because it is an expression of empiricism that is itself scientific. As we discussed earlier, the history of science itself motivates a degree of scepticism about science and especially about any claim to finality or completeness made on behalf of particular parts of contemporary science.

---

[21] Ibid., 5.

[22] *The Empirical Stance*, op cit.: 3.

[23] *Every Thing Must Go*, op cit., 234.

Van Fraassen's constructive empiricism is defensible on such grounds, and on the grounds that, in the end, what matters in science is making empirical predictions and that hence empirical adequacy is the aim of science. It is true that he has recently advocated his empiricism as a way of placing a limit on the claims of objectifying inquiry and a way of making the world safe for religion, but I am not sympathetic to constructive empiricism for that reason. Indeed, in so far as religions centrally involve doctrines concerning the nature of gods, messiahs and the special place of certain ethical and cultural groups in the history of the world, then they just *are* attempts at metaphysical theorizing. Presumably, furthermore, claims about, say, the unique corporeal manifestation of the divine a couple of millennia ago, are supposed to be objectively true, and so I don't understand the equation of 'the Copernican spirit' with the idea of objectification. Religion seems to me to be replete with objectifying discourse.

As for 'non-objectifying' modes of discourse, we say in the book, and I have implied as much in what I've said, that we do not see our attempts at naturalized metaphysics as rivalling or threatening the articulation of human subjectivity in art, literature, music or even in philosophical anthropology. Of course, the scientific worldview does incorporate us and it tells us about ourselves. Fundamentally, according to science, we are continuous in anatomy and physiology and to an extent in psychology with other animals. We find out many unpleasant things about ourselves from experimental psychology concerning our propensity to identify and persecute those not of our 'group', where the latter may be completely arbitrarily circumscribed. I think it is important that in our attempts to promote social justice and peaceful social living we be informed by the evidence concerning what we are actually like, not by idealized conceptions of personhood derived from our self-image which, like the manifest image, is replete with illusions. Of course, there is something to the claim that the first-person perspective per se cannot be objectively described; however, this does nothing to undermine the importance of using the most realistic models we can when deploying the third-person perspective. Again, as I have said above, naturalized metaphysics and science cannot tell us what to value, indeed the valuing of reason in itself is an extrinsic commitment to science, but that is no argument for adopting an anthropocentric or religious worldview.

Our repudiation of individual objects makes sense only in the context of how many philosophers think about them – it is the individuals of analytic metaphysics that we eliminate from our ontology, not the individuals of everyday life. Furthermore, once we have abandoned the false ideals of a privileged set of fundamental individuals, there is no reason to claim that macroscopic objects are less real or not real – hence our denial of physicalism. As for 'the spiritually anemic tastes of scientism', I think this phrase refers again to objectification, and again I say that naturalists are as capable of appreciating the value of life as anyone else.

You ask that I explain our positive ontology and so I will try to do so. In essence it amounts to seeing what follows once one accepts the idea that there is nothing more to the existence of an object than the necessity of incorporating it into any adequate and efficient predictive and explanatory theory of the world. Such theories are always applied to the world at certain scales of time and space, and often only in special locations, so we advocate what we call 'the scale relativity of ontology'. Tables, for example, are indispensable components of everyday ontology but would deliver no predictive or explanatory power to a theory designed to describe the world over scales of light years and eons, or over scales of nanoseconds and nanometers. The basic idea here is that of Daniel Dennett's 'real patterns'.[24] Don Ross developed Dennett's paper, which was about the philosophy of mind, into a defence of a kind of realism about all the special sciences.[25] We then developed the idea of synthesizing this with OSR. Our claim is that the view that things are scale-dependent patterns best accommodates both the repudiation of self-standing individuals in quantum and relativistic physics, and the ontological variety of the sciences as a whole.

C: In the first chapter of *Every Thing Must Go*, fittingly entitled 'In Defence of Scientism', you mount a strongly polemical attack upon contemporary analytic metaphysics, which you charge with 'sowing systematic confusion about the nature of the world, and how to find out about it'.[26] Analytic or 'neo-scholastic' metaphysics, you suggest, 'contributes nothing to human knowledge and, where it has any impact at all, systematically misrepresents the relative significance of what we do know on the basis of science'.[27] While often paying lip-service to science (and, for obvious reasons, to physics in particular), or else rhetorically emulating it, such philosophers typically rely upon commonsensical notions of classical physics according to which the physical world is essentially 'made of' myriad 'little things' and 'micro-bangings' – a conception of the physical world which, you argue, has long-since been rendered obsolete within physics itself. Essentially, what contemporary 'neo-scholastic metaphysics' and 'pseudo-naturalist philosophy' thereby do is attempt to 'domesticate' physics on the basis of an illegitimate extension of the manifest image of the world bequeathed to us by our natural history.

---

[26] *Every Thing Must Go*, op. cit., vii.

Earlier on you spoke of your despair with regard to many philosophers' insistence on 'trying to do metaphysics with categories like object and intrinsic property', which are 'anthropomorphic in the sense that they are a projection of how the everyday world of our experience is conceptualized'. Similarly, in *Every Thing Must Go*, quoting Ernan McMullin's remark that 'imaginability must not be made the basis for ontology',[28] you criticize the demand for an ontology based on individuals on the grounds that it is tantamount to demanding 'that the mind-independent world be imaginable in terms of the categories of the macroworld'.[29] However, you have also just said that your position does not entail the elimination of the individual objects of everyday life or the macroscopic objects of the manifest image from one's ontology. How, then, do you go about squaring these assertions? If the mind-independent world is *not* to be thought of as 'imaginable in terms of the categories of the macroworld', how can the individual objects of the macroworld nonetheless be regarding as 'no less real' than the 'real patterns' uncovered by fundamental physics? Are you really suggesting that it is only the way in which certain philosophers think about objects which is 'anthropomorphic', whereas our everyday or commonsensical notion of individual objects picks out something which really exists 'out there' in the mind-independent world?

---

[27] Ibid.

[28] The passage deserves quoting at length: 'The denizens of the microworld with their "strangeness" and "charm" can hardly be said to be imaginable in the ordinary sense. At that level, we have lost many of the familiar bearings [...] that allow us to anchor the reference of existence-claims in such macrotheories as geology or astrophysics. But imaginability must not be made the test for ontology. The realist claim is that the scientist is discovering the structures of the world; it is not required in addition that these structures be imaginable in the categories of the macroworld. [...] If the success of the argument at the macrolevel is to be explained by postulating that something like the entities of the theory exist, the same ought to be true of arguments at the microlevel. Are there electrons? Yes, there are, just as there are stars and slowly moving geological plates bearing the continents of earth. What are electrons? Just what the theory of electrons says they are, no more, no less, always

JL: Our polemic against analytic metaphysics will doubtless not persuade those already committed to it, but we hope at least to provide some solidarity to those who have their doubts about the direction the subject has taken. There is a debate that epitomizes the problem, as I see it, and that is central to the recent literature in analytic metaphysics, and it concerns the question of the conditions under which objects form composite objects. The options range from nihilism

---

allowing for the likelihood that the theory is open to further refinement. If we cannot quite imagine what they are, this is due to the distance of the microworld from the world in which our imaginations were formed, not the existential shortcomings of electrons [...].' Ernan McMullin, 'The Case for Scientific Realism', in J. Leplin (ed.), *Scientific Realism* (Berkeley: University of California Press, 1984), 14-15.

[29] *Every Thing Must Go*, op. cit., 132.

– there are only simple objects and no composites – to unrestricted composition – all mereological sums of simple objects form composite objects. Restricted composition – the natural position that only some collections of objects form composite objects – is considered difficult to defend because finding a non-arbitrary criterion for distinguishing genuine composites is apparently problematic. The analytic metaphysicians really are trying to decide whether or not tables are real – not because they doubt there is an external world, but because they worry that only table parts are real. At no point in these debates do any of the participants refer to the complex and fascinating science of, say, how molecules form liquids, or how atomic lattices form solids. Rather, the debates are conducted a priori and in exactly the same terms as they would be if modern science had never happened. In particular, they persist in operating as if the world can be visualized as composed of little objects, much as the Greek atomists thought, and they pay scant attention to the utterly bizarre nature of matter revealed by physics. This is especially frustrating because there are fascinating issues about individuation, both in physics and the rest of science, that are being neglected by philosophers. For example, in evolutionary biology there are rich puzzles about how and why individual organisms subsume themselves within cells, colonies, multi-cellular organisms, and social colonies. Metaphysicians have realized that people are beginning to wonder about their subject, so the fashionable issue now is called 'metametaphysics'. Apparently they are worrying about whether or not there is a special metaphysical sense of 'exists'. This all strikes me as evidence that the bandwagon is about to crash and burn – but I may be being optimistic.

According to us, then, those interested in metaphysics must look to science, liberate themselves from the strictures of what can be visualized, and avoid trying to 'domesticate' the theories they find by rendering them in terms of the manifest image. We also think that the notion of an 'object' is fundamentally tied to the practical purposes of prediction and explanation to which theories are put, starting with folk physics and folk biology. Whether or not the species concept will feature in a fully scientific evolutionary biology, human beings have an innate disposition to categorize animals into species – and with very good reason, because over the time scales and to the degrees of accuracy that are relevant to us, there are indeed stable kinds with stable properties, and getting them right mattered a lot to our survival. Similarly, while fundamental physics will never recognize the existence of tables at our time and length scales, tables are an essential part of any adequate and efficient ontology of our world. Real patterns are scale relative, and this is why tables are as real as atoms. Life is short and time is precious, so in general people have learned only to focus successfully on salient features of the world. Ones that stick around for a while are objects. The mistake philosophers make is to start asking questions like 'Is the table the same table if some parts are replaced?', or 'Is a neutrino passing through the table part of it or not?' If one is selling an antique table with a provenance then there may be a genuine need to ask whether it really is the same table that was made by a famous craftsman or whether it is a new table with old legs or whatever. However, there are many questions about tables to which we should expect no answer, because real patterns are necessarily approximate and scale dependent, unlike the hypostasized objects of philosophers.

Finally, note that the table as pattern is no less mind-independent for that. It is precisely because it does what it does independently of our beliefs, intentions and desires that it is a real pattern and not a fictitious one.

C: One of the principal reasons that many people regard 'scientism' as inherently objectionable is that they believe that it necessitates a drastic narrowing-down of the range of permissible ontological commitments such that only that which is quantified over by fundamental physics (on some construal thereof) may be regarded as fully real, everything else being a candidate for either (microphysicalist) reduction or straightforward ontological elimination. The charge, in short, is that a strictly physicalist ontology is a necessarily impoverished one inasmuch as it is by its very nature incapable of doing justice to the manifest image of the world – that world 'which spontaneously appears around me when I open my eyes' invoked by Eddington in his famous discussion of the problem of the relationship between the 'two tables' (i.e. the 'scientific' table of microphysics and the 'manifest' table of commonsense). While Eddington concluded that the scientific table 'is the only one which is really there – whatever "there" may be' and that the manifest table is thus a kind of anthropomorphic illusion (a 'strange compound of external nature, mental imagery and inherited prejudice'),[30] you argue that the everyday table is 'undoubtedly a real pattern', whereas '[s]trictly speaking there is no scientific table at all'.[31]

[30] Arthur Eddington, *The Nature of the Physical World*, (Cambridge, Cambridge University Press, 1928), xii.

[31] *Every Thing Must Go*, op. cit., 253.

While, on the face of it, this latter conclusion might sound like an endorsement of an instrumentalist stance vis-à-vis the 'theoretical posits' of physics, it is in fact motivated rather by a kind of instrumentalism about individual objects (both those of everyday life and the special sciences). Given your rejection of ontological physicalism (due to its incompatibility with naturalism more broadly construed),[32] and the fact that the special sciences (including non-fundamental physics) 'are richly populated with individual objects',[33] it is one of the principal objectives of your project of unification to explain the relationship between fundamental physics and the special sciences, and to do so in consilient rather than reductionist terms. As you have already mentioned, two of the key theoretical innovations which you have introduced for this purpose are the 'scale relativity of ontology', on the one hand, and a certain instrumentalist stance vis-à-vis individual objects, on the other. While, as you have said, it is the former (scale relativity) which is supposed to guarantee the reality of individual objects like tables or organisms or persons, one might nevertheless wonder whether this is not somewhat in tension with the latter instrumentalism regarding individual objects. If the objects of the special sciences are to be regarded as 'pragmatic devices used by agents to orient themselves in regions of spacetime, and to construct approximate representations of the world',[34] 'only epistemological book-keeping devices',[35] 'constructs built for second-order tracking of real patterns', or 'community representations',[36] how can they at the same time be regarded as fully (i.e. mind-independently) real? Moreover, if 'to be is to be a real pattern', how can real patterns, as you have just put it, be 'necessarily approximate'? Is there not perhaps a certain equivocation between *representatum* and *representandum* here; that is, between real patterns as representations, on the one hand, and as that which is represented, on the other? Perhaps the distinction you draw in *Every Thing Must Go* between second-order ('representational') real patterns and first-order ('extra-representational') real patterns might shed some light on this?[37]

[33] Ibid., 130.

[34] Ibid.

[35] Ibid., 240.

JL: 'Instrumentalism' is a term subject to many interpretations. Normally it connotes the view that the theoretical posits of science are cognitive tools for predicting the phenomena rather that real entities. However, our instrumentalism is universal and admits of no contrast between real objects and mere posits. According to our view, individuation is always a cognitive tool that is used to predict and explain the world at some scale of resolution. The objects of the special sciences and everyday discourse are 'fully real' just because there is nothing more to being a real object than being a real pattern. When it comes to mind-independence the point is that any observer wanting to track the world at a particular scale with respect to particular features will fail to do so most efficiently if they do not quantify over the real patterns. However, reality only coalesces into real patterns at all if one is restricted to a particular level of accuracy. Consider what happens in quantum field theory where all the known theories can only be applied when length-scale cut-offs are imposed to prevent infinities appearing in the equations. Of course, it is hoped that a more fundamental theory will be found that does not have such limitations, but whatever the details of it are I think it is a fairly safe bet that it will not describe the world as being composed of some set of individuals, but rather will describe some sort of structure. In the book we are agnostic about whether there will ever be a final theory in fundamental physics. Either way, we argue that our everyday and special scientific conceptions of objects are cognitive tools for getting a grip on the structure of the world. The scale relativity of ontology and the idea that to be is to be a real pattern are hence not in tension but are rather two-sides of the same metaphysical coin.

---

[36] Ibid., 242.

[37] Ibid., 243.

The distinction we make between first-order and second-order real patterns is not intended to be a metaphysical one, but to draw attention to the fact that the patterns we find in the world – tables for example – are patterns in phenomena that themselves are already cognitively picked out as real patterns – such as properties like macroscopic shapes, colours and textures. Many of these latter real patterns are discerned and packaged for our cognition by our basic perceptual systems. According to us all individuals are second-order real patterns in this sense. We seem to confuse representations with what is represented for our aim is to undermine the distinction when it comes to individuals. However, since it is possible to bump into tables they cannot be mere representations, so our view seems nonsensical.

I hope not, but it must be very carefully stated. When one describes the phenomena as someone bumping into a table one is representing the world at a certain scale and to a certain degree of accuracy. Fundamental physics could have no use nor attach any meaning to such a description and so in this sense the table is merely a representation; but all objects are like this, and so the table is as real as anything could be. Some real patterns are more representational than others though, insofar as they only exist because of the contingencies of our actual representations and their historical development. Hence, while any observer interested in certain scales of resolution would have to quantify over stars and planets, only someone in our particular cultural milieu needs to quantify over Sherlock Holmes. Fictional characters are real patterns but not universal ones.

C: When you say that a table is a representation inasmuch as fundamental physics does not quantify over such things, and yet that, since this is the case for all objects, 'the table is as real as anything could be', is the implication that while a table is as real as any *thing* could be, *things* as such are nevertheless not ontologically fundamental, but must rather cede their traditional place of metaphysical priority to *structures*? This much, at least, would seem to be required by your OSR, according to which there is nothing but 'structure all the way down'. Yet what exactly is it which OSR affirms to be ontologically fundamental when it insists that 'structure' is all that there is? Is it mathematical structure itself, or is it those 'extra representational real patterns' which mathematical structures are taken to represent? If it is the former, you would of course be committed to a radical form of

Platonism or Pythagoreanism akin to Max Tegmark's 'Mathematical Universe Hypothesis';[38] if it is the latter, how are we to understand the relationship between the mathematical theories and the metaphysically-real structures which they supposedly track?

JL: This question gets to the heart of the matter and I must confess that I am not sure what the answer to it is. The idea of structure that I have in mind is that of modal structure – nomological structure – rather than mathematical structure. However, it might be that the necessity of mathematics and the physical necessity of laws coincide, and the history of physics has progressively undermined the distinction between mathematical and physical necessity. We do not advocate Pythagoreanism or Platonism, because they contrast mathematical or formal existence with material being. Our metaphysics is directly motivated, just as we say all metaphysics should be, by the actual content of physics, and our review of the latter significantly undermines the distinction between mathematical and physical-nomological structure. However, if mathematical structure does not coincide with physical structure then the relationship between them is surely that of isomorphism (or something similar but weaker such as homomorphism). As to what makes the difference between concretely instantiated mathematical structure (physical structure) and purely mathematical structure, I think that any attempt to say so would amount to empty words that would in the end add nothing to our understanding of the difference. I have no idea what conceptual resources one could deploy to say more about a distinction that, if it obtains, is so fundamental.

---

[38] Max Tegmark, 'The Mathematical Universe', *Foundations of Physics* 38, 2008: 101-150.

C: According to OSR 'structure is all there is', yet doesn't the very concept of structure require as its complement something which is *not* structure? In this regard, Bas van Fraassen has argued that the very distinction between 'content' and 'structure' is 'painfully context-dependent',[39] and that the continuity of structure upon which structural realism's proposed solution to the history of science induction hinges is identifiable only *retrospectively*, rendering the solution both circular and ad hoc: 'The atoms are still there at some level, so that was structure. The ether is no longer there, at any level, so that was a mistake about content'.[40] Thus, van Fraassen asks: 'Is it not a little embarrassing to start with the thesis that what is preserved through scientific revolutions is the structure attributed to nature, and then to have to identify structure by noticing what has been preserved? Must this philosophy of science [not] ultimately rest on a metaphysics to distinguish intrinsic and extrinsic properties (essences and accidents, substantial form and prime matter, relation and pure quality)?'[41] How do you respond?

JL: I respond by saying that some of the structure of the ether is retained and what is retained is more than the pure empirical content of the ether theory. In every revolution in physics much of the mathematical structure of the old theory is recoverable from the new theory. It is not just a matter of the predictions coinciding. The Galilean transformations and the inverse square law of classical mechanics are reached as approximations from relativity theory. Of course we can only say retrospectively exactly which aspects of current science will be retained in its future form, but we can say prospectively that all the well-confirmed laws, and not just the empirical content of the theories, will be recoverable from the next generation of theories. According to OSR the theoretical content of theories tracks the nomological structure of the world and not just the empirical regularities.

[40] Ibid., 290.

[41] Ibid., 303.

C: Isn't it the case that what, at one stage of the history of science, is taken to be 'extra-representational' is at a later stage found to be 'representational'; in other words, that what is at one time taken to be describe the fundamental structure of physical reality is at a later time shown to be at best only an approximate limiting case of a more comprehensive theory, holding relative to a certain set of special conditions or domain of application? But if that is the case, how can it be legitimate to suggest that we are now in possession of knowledge of 'extra-representational real patterns' at all? Might it not rather suggest that the very distinction between 'representational' and 'extra-representational' real patterns is an epistemologically suspect one, and that we might be better-off talking instead (in the manner of Ernst Cassirer and, more recently, Michael Friedman)[42] about a continuously converging series of mathematical structures in which the extra-representational real (the 'thing in itself', if you like) is at best a regulative ideal which science only asymptotically approximates?

---

[42] See, e.g., Ernst Cassirer, *Substance and Function and Einstein's Theory of Relativity* (London: Dover, 1923); Michael Friedman, *Dynamics of Reason* (Stanford: CSLI,

JL: I agree that the most serious challenge to OSR comes from empiricism and not from scientific realism or analytic metaphysics. Van Fraassen and Friedman present this challenge in different ways because Friedman's view cedes no ontological priority to the manifest image. The thing that makes me disagree with Friedman is that I am confident that the causal and nomological structure of reality as revealed by our best science (and as approximated to a fairly good degree by common sense ontology) amounts to knowledge of real patterns that will be retained in the future. However, the idea of a real pattern is not the idea of a thing in itself, which I agree is at best a regulative ideal.

C: Perhaps the most widespread and persistent objection to OSR is that it makes no sense to talk about *relations* without *relata*; or, in other words, that the very notion of a relation presupposes *objects* which *stand in* the relations. It is on the basis of this assumption that many philosophers, while admitting that physics only tells us about the 'relational properties' of things, nevertheless insist that there must also be 'intrinsic properties' upon which the former supervene, thus motivating only an 'epistemic' or 'Kantian' structural realism (ESR) rather than the strong metaphysical or 'ontic'

2001); and Michael Friedman, 'Ernst Cassirer and Contemporary Philosophy of Science' in D. Veal (ed.) *Continental Philosophy and the Sciences: The German Tradition*, Special Issue of *Angelaki* 10 (1), 2005: 119-28.

variant (OSR) which you endorse. What is your response to this criticism? Is it only an especially stubborn metaphysical article of faith that there must be unknowable intrinsic properties (analogous to Kant's 'thing in themselves') upon which the relational properties revealed by fundamental physics must supervene? Why is it that you insist upon adopting an eliminativist rather than an agnostic stance with regard to the existence of 'intrinsic properties'?

JL: The notion of an intrinsic property is usually defined as a property which an individual possesses or not regardless of what else exists. In the philosophy of physics it has become extremely dubious to suppose that individuals exist independently of other individuals. Once the idea of classical atoms as paradigmatic of individuals is abandoned, although one can make sense of saying that all properties are intrinsic properties of the universe, the pragmatic point of saying that is obscure, to put it mildly. Note, however, that the question of whether everything supervenes on intrinsic properties is different from whether there are any intrinsic properties at all. Many philosophers would concede that there may be some relational properties that do not supervene on the intrinsic properties but insist that the latter must also exist.

C: If OSR was proposed solely as a solution to the pessimistic meta-induction, it would be open to the charge that it is ad hoc, but as you have already said, it is also motivated by reflection on quantum mechanics and general relativity. In particular, you argue that the ubiquity of quantum entanglement provides us with an empirically underdetermined choice between either individuating each particle with respect to some transcendent metaphysical haecceity or else jettisoning the notion of individuality altogether in favour of a structuralist ontology, and that the latter option is preferable on grounds of ontological parsimony. Yet as Paul Dicken has argued in his review of your book, all of this is a debate over the *interpretation* of quantum mechanics, and it is therefore hard to see how a naturalistic injunction to reject any hypothesis that 'conflicts with fundamental physics' (as your 'Primacy of Physics Constraint' demands) could decide the matter either way.[43] After all, as Dicken points out, '[i]f primitive this-ness *conflicted* with fundamental physics, it would never have been a potential *interpretation* of fundamental physics in the first place'.[44] You say in your book that 'we can cite instances of leading physicists who motivate our metaphysical approach from strictly physical considerations';[45] yet, given the problem of metaphysical underdetermination, is it not the case that one could equally cite other physicists, with very different interpretations, and thus come up with a list of constraints that would be incompatible with those which you have picked out? In other words, isn't the criterion according to which something might be taken to conflict or not to conflict with fundamental physics itself somewhat hopelessly underdetermined?

---

[43] *Studies in History and Philosophy of Science* 39 (2), 2008: 290-3, at 292.

[44] Ibid.

[45] *Every Thing Must Go*, op. cit., 61.

JL: The Primacy of Physics Constraint is not meant to decide the matter. Rather it is supposed to capture the correct insights of the physicalism and reductionism that we otherwise reject. Our argument for eliminativism about self-subsistent individuals is based in part on the ad hoc manoeuvres that have to be made to make fundamental physics compatible with them, and in part on the consilience of our overall metaphysics which does not include them, but we do not take conflict to mean outright inconsistency. I think everyone will agree that there is at least a prima facie conflict between the metaphysical commitment to a world made of some set of fundamental individuals, and quantum mechanics and general relativity. Whether that conflict is there on further consideration is a matter for people's judgement and not a matter of logic. However, we claim to have given reasons to think that the right judgement, in the round, is to break the underdetermination of metaphysics by physics and the rest of science in favour of structuralism. The point about OSR and our overall metaphysics is that our naturalism requires us to abandon it if it does not express a unifying picture of the world that is both compatible with and motivates successful science.

C: The central component of your scientism is your verificationism. While the latter term is nowadays still habitually associated with the failures of the logical positivist demarcationist programme – a failure which, you suggest, paved the way for the subsequent recrudescence of neo-scholastic metaphysics – your own verificationism is not based upon any a priori philosophical criteria of meaning-satisfaction but rather upon the institutionally-selected epistemic reliability of science itself. To cite a relevant passage:

> We admire science to the point of frank scientism [...] what most impresses us about science is not its results – marvellous though these have been – but the way in which its institutional organization selects for rationality and collective epistemic progress in the activities of a species that seems, in its more natural institutional settings, strongly disposed to superstition and fearful conservatism. Our verificationism, like all versions of that, is promoted as a bar against seeking explanation where we have good reasons to doubt that it promises anything but temporary psychological satisfaction at the expense of truth. In particular, we deny that there is value to be had in philosophers postulating explanantia, without empirical constraint, on the grounds that these would make various putative explananda feel less mysterious if they prevailed.[46]

That the institutional error filters of science indeed rigorously select for optimal rationality in a way that few other institutions may claim to even approximate seems incontrovertible. However, isn't there a risk here that making theoretical research entirely subordinate to internal institutional mechanisms of selection might result in a certain counterproductive conservatism or conformism, even a severe diminution in the range and diversity of active research programmes? After all, when talking about such institutional filters here we are not only talking about an ongoing intersubjective process of rational and self-correcting inquiry but also about the power-politics of hiring committees, funding agencies and government institutions. In this regard Lee Smolin has argued in his recent book

---

[46] *Every Thing Must Go*, op. cit., 61-2.

The Trouble With Physics that comparatively little progress has been made in fundamental physics over the past three decades precisely because of the way in which certain firmly entrenched institutional filters have served to perpetuate not only a particularly narrow approach to scientific problem-solving but also a particular research programme – namely, string theory – at the expense of its rivals.[47] According to Smolin, string theory 'now has such a dominant position in the academy that it is practically career suicide for young theoretical physicists not to join the field', since 'theorists who pursue approaches to fundamental physics other than string theory have almost no career opportunities'.[48]

It is well known that string theory hardly even qualifies as a candidate physical theory at all, given that nobody seems to have the slightest idea of how to test it. But given that you tie your verificationism so firmly to the processes of institutional selection rather than empirical confirmation or falsification per se, oughtn't the aforementioned institutional hegemony of string theory commit you to embrace the latter as the currently most promising approach to physical unification, despite the fact that your structuralist metaphysics would seem to be more in line with 'relational' interpretations of quantum mechanics such as those proposed by Rovelli and Smolin? Moreover, isn't it the case that it is not only philosophers but also scientists themselves who postulate explanantia 'on the grounds that these would make various putative explananda feel less mysterious if they prevailed'? One thinks, for example, of the popular idea of the postulation of some kind of multiverse in order to 'explain' the putative 'fine-tuning' of the cosmological constants or else to 'explain' the fact that string theory comes in more versions than all the atoms in the known universe. Thus, isn't it the case that a good deal of (institutionally heavily-funded) research in contemporary quantum gravity and cosmology is in this respect at least as 'empirically unconstrained' as anything which one might find in analytic metaphysics?

---

[47] Lee Smolin, *The Trouble With Physics: The Rise of String Theory, The Fall of Science, and What Comes Next* (Boston and New York: Houghton Mifflin, 2006); see also Peter Woit, *Not Even Wrong: The Failure of String Theory and the Search for Unity in Physical Law* (New York: Basic Books, 2006).

[48] Smolin, *The Trouble With Physics*, op. cit., xx, xxii.

JL: String theory became popular largely because the existence of spin-2 massless bosons (gravitons ought to be exactly this kind of particle) dropped out of its formalism without being put in by hand. However, Smolin is right that string theory cannot claim any novel predictive success, and, while it is certainly well-funded, I do not think the majority of experts in fundamental physics would say that string theory has the same claim to truth as quantum mechanics or general relativity or even the standard model. It may well be that the institutional processes of science have not functioned particularly well in this case, and it may also be the case that they are not in general that great. Our book contains no arguments against the claim that there is a pressing need to improve and reform science. However, we do think that there is no other epistemic game in town.

Of course scientists also make explanatory posits, but in the end empirical consequences and predictions are what make or break theories in science. There is a big difference between the established theories in physics and the far-out speculations of contemporary theorists that attract the attention of the layperson. I am extremely sceptical about multiverses, and certainly theories associated with them would have to acquire more empirical success before they would be counted as scientific knowledge. Indeed, the 'fine-tuning' problem may be bogus since its formulation relies upon a modal distinction between laws and boundary conditions that might be spurious.

However, the general point that scientists sometimes engage in metaphysics is well-taken and sometimes they too allow themselves to get carried away. I also think that philosophers can and do carry out work that is continuous with scientific theorizing and of scientific value (for example, within the philosophy of physics or the philosophy of biology), but in recent years the field known as analytic metaphysics has been largely characterized by inquiry that ignores science altogether, or by work which addresses a domesticated and distorted scientific image (we call this the philosophy of A-level chemistry). My view is that metaphysical theorizing should always be based on or at least inspired by scientific knowledge rather than intuitions and conceptual analysis (although the latter obviously has a role to play in promoting clarity of thought generally); and also that, whether metaphysics is being carried out by philosophers or scientists, contact with experience must be considered the supreme court. In this sense I have a view of metaphysics very like that of van Fraassen – namely, that it is of epistemic value only in so far as it contributes to the progress of science.

C: Perhaps you could qualify more precisely what you mean by 'experience' and the relevant sense of 'contact' here, since the idea that 'contact with experience must be considered the supreme court' is of course one which would be endorsed by philosophers representing a wide variety of different approaches, yet you surely do not mean by 'experience' here either the 'sense perception' of traditional positivism, the 'lived experience' of the phenomenologists, nor – in spite of your expression of kinship with van Fraassen – anything which depends upon an anthropocentric distinction between what is and what is not humanly observable. Indeed, as we were saying earlier, many philosophers continue to reject the ontological import of modern physics precisely on the grounds that it seems to make *too little* 'contact with experience' in their preferred sense of the term, substituting a 'mathematically substructed world of idealities for the only real world, the one that is actually given through perception', etc. In this regard, it seems important to point out that your verificationism substitutes for the traditional empiricist criterion of *observability* the broader notion of *informational connectedness.*[49] Could you say a little about what this means, and why you deem this substitution to be necessary?

JL: The idea of 'contact with experience' I have in mind includes the traditional empiricist idea of sense perception but also includes the way we have extended our empirical contact with the world using instruments and measuring devices. All such systems have in common that they have degrees of freedom that become correlated with (contain information) about states of the world. By 'informational connectedness' we refer to a kind of contact between states of the world and subsystems of it that is very general and so does not commit us to doctrinal empiricism. When we talk about 'information' in the book we always have formal information theory in mind. There is an informational connection wherever there's a system with particular detecting capacities, a set of properties that are transduced, and a channel that explains the covariance between aspects of the transduced properties and some states of the transducer. A person, as one kind of transducer, is informationally connected from spacetime coordinates *s* to any part of the world *w* when there exists a channel such that records of properties measurable at *w* are transmitted to *s* in a way that a person, equipped with physically possible technology, could recover, and it's physically possible that the person could position themselves at *s*. This isn't supposed to be an analysis of anything, but a description of an important distinction, namely that between states of affairs one *could* set out to empirically investigate if one had a big enough budget, and states of affairs one could not. If the Big Bang was truly a singularity – and of course it might not be – then no one is informationally connected to the other side of it and our verificationism is then the claim that it's silly to speculate about that because anything one can imagine is as probable (in the Bayesian sense) as all the members of an infinite set of descriptions that no person *would* imagine. As always, the scale relativity of ontology applies here. So, to cite an example we use in the book, we're all informationally connected to the approximate amount of hair

---

[49] *Every Thing Must Go*, op. cit., 303-10.

Napoleon had on his head at Waterloo because we have paintings, plus records from his contemporaries that don't say he was bald but some of which would have if he had been. But we living today are informationally unconnected with the precise number of hairs Napoleon had that day and it would be foolish to speculate about whether he had x or $x+1$ or $x-1$. Our verificationism doesn't involve any deep thesis but is a form of being practical that scientists themselves observe.

C: In his classic essay 'Empiricism and the Philosophy of Mind',[50] Wilfred Sellars makes the interesting point that whereas before there was any such subject as 'the philosophy of science' all students of philosophy felt obligated to keep 'at least one eye' on the methods and findings of the sciences, once philosophy of science came to have 'nominal as well as real existence' there arose a temptation 'to leave it to the specialists, and to confuse the sound idea that philosophy is not science with the mistaken idea that philosophy is independent of science'. What this gave rise to, suggests Sellars, was the view according to which 'philosophers of science deal with a mode of discourse which is, so to speak, a peninsular offshoot from the mainland of ordinary discourse. The study of scientific discourse is conceived to be a worthy employment for those who have the background and motivation to keep track of it, but an employment which is fundamentally a hobby divorced from the perplexities of the mainland'. Aided and abetted by an instrumentalist conception of science according to which the categories of the manifest image have an 'unchallengeable authenticity' and the theoretical apparatus of the sciences is a mere 'auxiliary framework', this in turn ultimately paved the way for a resurgence of the kind of neo-scholastic metaphysics which you rail against in your book. Could this be one of the reasons that you call what you do 'metaphysics' rather than 'philosophy of science'? Given that, as Sellars says, 'nominal causes [...] have real effects', is it time that philosophers of science wrestled the banner of 'metaphysics' from the neo-scholastics and, as it were, reoccupied the mainland of philosophical discourse?

---

[50] All of the quotations which follow are taken from section IX, 'Science and Ordinary Usage', in Wilfred Sellars, *Science, Perception and Reality* (Atascadero, California: Ridgeview, 1963), 170-74.

JL: It is certainly true that much work has been done by philosophers of science, on for example, causation, laws of nature, natural kinds and so on, that definitely counts as metaphysics. Perhaps I should explain how we came to write the polemic against analytic metaphysics in the first place. We did not set out to write a book that began by attacking other philosophers, but rather to synthesize ontic structural realism and rainforest realism into a unified metaphysics applicable to science from physics to economics. We then realized that we were writing a book about metaphysics but that we were neither reading nor discussing the work of the most prominent metaphysicians of our time, but were engaging only with the literature in general philosophy of science and the philosophy of the various special sciences. At the same time we were encountering the resurgence of analytic metaphysics within philosophy and finding ourselves frustrated by its insularity and lack of engagement with the sciences. Hence, we decided to write a methodological introduction that explained why a book about metaphysics was ignoring the metaphysical literature. Once we started doing that we warmed to our theme and became convinced that what we were saying needed to be said quite independently of the rest of our project. What we say is deliberately polemical and less nuanced than it might be. Of course, there is no sharp distinction between good naturalized metaphysics and bad analytic metaphysics, or between the people who do these things. However, it is undeniable that one of the most significant developments in analytic philosophy in recent years has been the growth in power, prominence and status of metaphysics, and we stand by the claim that this is generally a bad thing for philosophy since it has led to a concentration on internally-generated philosophical problems and a failure to look outwards. By adopting the subtitle 'Metaphysics Naturalized' for the book we hoped in part to stake a claim for the mainland; however, so far I have seen no evidence that we have been successful.

C: The role which your book assigns to the philosopher vis-à-vis the sciences is very much that of an 'underlabourer' in which philosophers help to build bridges (that is, to trace networks of consilience) between already-established domains of scientific knowledge. However, one might wonder if the history of science, and that of physics in particular, does not suggest the need for an even more intimate relationship between science and philosophy than this. The historical divorce between science and philosophy is, after all, a very recent one, hard as it often is for us to remember that fact. In this regard, not only philosophers and historians of science such as Lawrence Sklar, Michael Friedman and Thomas Ryckman[51] but also physicists such as Lee Smolin and Carlo Rovelli[52] have emphasized the crucial role of an ongoing dialogue between philosophy and physics, especially in times of revolutionary transition in the latter. What is needed at the time of the present 'unfinished revolution' in physics, they suggest, is radical reflection on the very conceptual foundations of physics, and they urge philosophers to take a more active and constructive role in these discussions; thus Rovelli writes:

> if a new synthesis is to be reached, I believe that philosophical thinking will be once more be one of its ingredients. Due to the conceptual vastness of the problematic involved, the generality and accuracy of philosophical thinking and its capacity to clarify conceptual premises are probably necessary to help physics out of a situation in which we have learned so much about the world, but no longer know what matter, time, space and causality are. As a physicist involved in this effort, I wish that philosophers who are interested in the scientific conception of the world would not confine themselves to commenting [on] and polishing the present fragmentary physical theories, but would take the risk of trying to look *ahead*.[53]

Callender and N. Huggett (eds), *Physics Meets Philosophy at the Planck Scale* (Cambridge: Cambridge University Press, 2001).

[53] Carlo Rovelli, 'Halfway Through the Woods: Contemporary Research on Space

Given your own underlabourer conception of the role of the philosopher, is this an invitation which you think philosophers of science ought to turn down?

JL: Some philosophers have the capacity to work at the cutting edge of physics or theoretical biology, and have done so and of course should continue to do so. I see no reason why philosophers should not try and look ahead, but then since so many of them insist on looking backwards, even getting them to catch up with the present seems hard enough. However, let me emphasize that within the subfield I know best, namely the philosophy of physics, there are a great many superb intellects engaged in subtle and deep explorations of the conceptual foundations of the most advanced theories and these people are often engaged in looking ahead to some extent (I am not including myself among their number since my knowledge of quantum field theory and general relativity is not nearly good enough for me to look beyond them).

C: Finally, what advice might you have for those who may be convinced by your arguments for the need for a philosophical naturalism which goes beyond a vague sort of 'science-friendliness', yet who are nevertheless daunted by the prospect of doing metaphysics in the way that you recommend; in other words, those who may be not so much afraid of 'scientism' as intimidated by the kind of interdisciplinary omnicompetence that a project such as

---

and Time' in J. Earman & J. Norton (eds), *The Cosmos of Science* (Pittsburgh: University of Pittsburgh Press, 1997), 182.

yours would seem to demand? Since you argue that a priori metaphysics 'should be discontinued'[54] and exhort contemporary philosophers to 'come back and rejoin the great epistemic enterprise of modern civilization',[55] what exactly would you advise them to do? Should they simply put aside their philosophy books and start reading up on physics, chemistry, biology, cosmology, neuroscience, economics, linguistics, anthropology ...? You said yourself earlier in the interview that science is 'vast, complicated and hard to learn'. Is there really any hope of scientifically- and mathematically-untrained philosophers being able to contribute to the kind of bridge-building which you claim is the only viable form of metaphysics? Isn't there the risk that such philosophers will only end up perpetuating yet more 'pseudo-naturalist' metaphysics due to their superficial acquaintance with the methods and findings of the sciences?

JL: The worry you raise here is a genuine one and it often concerns me given my own avowed feelings of inferiority with respect to theoretical physics. In short I think the answer is not to put away philosophy books but to make sure that one reads the relevant other subjects too. For example, many of my colleagues at Bristol work in the philosophy of mathematics and logic. They continually educate themselves in set theory, category theory, various logical systems and so on. Similarly, I do think that philosophers of mind ought to be reading about the science of the mind, political philosophers ought to be reading about history, politics and economics, and so on (as indeed plenty of them do). The fact that there is a vast amount of learning to be had is no excuse for turning aside from the world and looking inwards. Philosophers in my experience are on the whole incredibly intelligent and astute. When they turn their minds to something they quickly spot ambiguities, conflations, incipient contradictions and so on. There is plenty of confusion and poor reasoning in science which they could help to sort out. Furthermore, there is another obvious solution to the problem you raise, namely: collaboration. Papers in particle physics are often written by a hundred or more people. Science in general is now so vast and highly developed that more and more work is done by teams of people. I see no reason why philosophers and scientific specialists cannot work together to integrate philosophy and science.

Enlightenment 2.0

Interview with Thomas Metzinger

Thomas Metzinger's work is at the forefront of interdisciplinary research between the philosophy of mind and cognitive neuroscience. Marrying an encyclopedic grasp of the philosophical literature on consciousness with a superlative mastery of the latest neurobiological research, his Being No One *is a groundbreaking work that recasts the terms in which the problem of consciousness is formulated. Although advances in cognitive neuroscience over the past twenty years have sparked a notable resurgence of interest in this problem among philosophers, many have argued that consciousness cannot be reductively explained by cognitive neuroscience, while others have gone so far as to insist that consciousness is a mystery that cannot be explained tout court, and that cognitive neuroscience lacks the resources to tackle 'the hard problem' of explaining how first-person subjective consciousness could ever arise from un-conscious neurophysiological processes. In our interview, Metzinger discusses not only how he confronts this philosophical challenge head-on by forging new conceptual resources capable of bridging this allegedly irreducible 'explanatory gap', but also how innovations such as the concept at the heart of his new theoretical framework – the 'phenomenal self-model' – might impact upon the personal and social experience of being human.*

COLLAPSE: At the beginning of *Being No One*[1] you criticize the tendency towards 'arrogant armchair theorizing' in what you call 'analytical scholasticism' in the philosophy of mind, a tradition which you charge with 'ignoring first-person phenomenological as well as third-person empirical constraints in the formation of one's basic conceptual tools'. Rather than taking into account empirical constraints on concept formation, such neo-scholastic 'armchair philosophers' will often explicitly stipulate that it is our commonsense or 'pre-philosophical' intuitions which must 'serve as the benchmark for a satisfactory account'.[2] But while you agree that such intuitions 'have to be taken seriously', you are scornful of the idea that they should serve as the *explanans* rather than the *explanandum* in the philosophy of mind, pointing out that it may well be the case that 'our best theories about our own minds will turn out to be radically counterintuitive', presenting us with 'a new kind of self-knowledge that most of us just cannot believe'. Though you suggest that 'nobody ever said that a fundamental expansion of our knowledge of ourselves has to be *intuitively* plausible', it is unfortunately the case that many philosophers of mind continue to act as if that were precisely the case. As Daniel Dennett has recently characterised the situation, philosophers of mind have typically proceeded 'as if the deliverances of their brute intuitions were not just *axiomatic-for-the-sake-of-the-project* but *true*, and, moreover, somehow inviolable'. Whereas in most sciences

---

[1] Thomas Metzinger, *Being No One: The Self-Model Theory of Subjectivity* (Cambridge, Mass.: MIT Press, 2004). The quotations in this paragraph are taken from pages 1-3 of the book.

[2] Tim Thornton, *Wittgenstein on Language and Thought* (Edinburgh: Edinburgh University Press, 1998), 1.

‘few things are more prized than a counterintuitive result’, given that it ‘shows us something surprising and forces us to reconsider our often tacit assumptions’, in philosophy of mind a counterintuitive result is ‘typically taken as tantamount to a refutation’.[3]

In your own work, you are not content with simply reversing this order of priorities by taking the commonsensical intuitions and concepts of the folk and the philosophers as the *explanandum* rather than the *explanans*; you also aim to provide an account of precisely how such deeply ingrained intuitions, and the philosophical conservatism which follows from them, are ‘ultimately rooted in the deeper representational structure of conscious minds’. So for you, explaining consciousness and subjectivity is not simply a matter of ‘changing the way we talk’, but of forging conceptually convincing links between sub-personal and personal levels of description which are *empirically* rather than *intuitively* plausible. Can you say more about what this project of ‘interdisciplinary philosophy’ involves, and the kinds of ‘empirical constraints’ which have guided the formation of your own conceptual tool-kit?

THOMAS METZINGER: Daniel Dennett is of course right – there is a certain deflationary Gestus in a lot of good, professional analytical philosophy of mind, and it sometimes blocks progress by simply being conservative without independent argument. There may be deeper evolutionary reasons for this attitude (quite obviously, our brains are 'coherence engines', maximizing the coherence of our internal model of reality at any point, often sacrificing veridicality for short-term functional adequacy, with the 'goodness of fit' then being what determines the degree of intuitiveness of a given thought), as well as reasons based in the history and culture of analytical philosophy – which was itself a revolutionary enterprise in the past, a beautiful rebellion against academic pretentiousness and narcissistic obscurantism. I do not want to speculate about these reasons any further, but obviously, to talk in an unnecessarily 'revolutionary' tone and to cultivate counterintuitive interpretations of empirical results in order to achieve media attention (a strategy sometimes found in neuroscience) is not the solution either. It could be just another kind of corniness.

---

[3] Daniel Dennett, *Sweet Dreams: Philosophical Obstacles to a Science of Consciousness* (Cambridge, Mass.: MIT Press, 2006), 34.

Our resources are limited. My intuition (!) is that, in these exciting times, we should not waste *too* much time and energy investigating what *exactly* the relationship between philosophy of mind and, say, neuroscience, cognitive science or AI ideally should be. Rather, in this particular historical epoch, I think further epistemic progress can be generated by philosophy becoming partly embedded into interdisciplinary research programs, following a strategy which one of my best critics, Josh Weisberg, has called the 'method of interdisciplinary constraint satisfaction' (MICS).[4] Part of the idea is to first confine ourselves to homing in on the target phenomenon in the actual world, using all sources of information available from every single discipline researching the human mind, in order to compress the space of possible solutions dramatically. Then we can see whether, in the course of this historical phase, empirical results have actually changed some of our deeper, theoretical intuitions. Maybe then we might have a better idea of how intuitions evolved in the first place; what concepts actually are; why exactly certain forms of self-deception were adaptive and became superbly robust, spilling over into the enterprise of philosophy and science itself – or perhaps even what actually rendered unargued conservatism and corniness successful strategies in primate societies and the world of our ancestors. Let's say we are interested in consciousness, or in a specific issue like non-conceptual self-consciousness: instead of kicking the problem upstairs into formal semantics and modal logic (i.e., by making *modal* intuitions explicit; intuitions which themselves have an evolutionary history), and instead of analyzing the sociohistorical accident of how we happen to talk about our own minds today, we should perhaps strive to invent a new form of philosophizing, which would be partly data-driven and conducted by philosophers who do not just *talk* about 'first-person methods', but actually *are* phenomenologically well-travelled.

---

[4] See J. Weisberg, 'Consciousness Constrained: A Commentary on *Being No One*', *Psyche* 11 (5), 2005, and Metzinger's 'Reply to Weisberg: No Direction Home – Searching for Neutral Ground' in *Psyche* 12 (4), 2006. These papers, as well as a Symposium on *Being No One* can be found online at http://psyche.cs.monash.edu.au/.

C: Cultivating counterintuitive interpretations of the results of the empirical sciences in order to grab media attention would be 'corny' indeed. Yet the fact remains that much of modern natural science is really in no *need* of any such deliberate 'cultivation' in order to bring out its 'counterintuitive' nature, quite simply because it explores aspects of reality to which our evolutionary ancestors simply had no access, and in regard to which it would therefore not have been reproductively advantageous for them to develop any 'intuitions'. This is a point, of course, which you develop at length in *Being No One* with regard to the likely evolutionary provenance of what you call our 'naive-realistic self-misunderstanding'. Indeed, the 'self-model theory of subjectivity' which you formulate is not only something which is 'radically counterintuitive' *for the time being*, as it were – the kind of theory which is deeply unsettling at first but is destined ultimately to be absorbed into the culture at large – but is something which you insist will necessarily *always* remain counterintuitive. 'Even if you are intellectually convinced by the current theory', you write, 'it will never be something *you* can believe in'.[5] Thus, you insist that we can never come to intuitively believe, properly digest or internalize the fact that the 'selves' which we take ourselves to be *do not in fact exist*.

But in this regard you have sometimes been accused of having cultivated an unnecessarily 'radical' or 'counterintuitive' interpretation of empirical results yourself. Of course, science frequently discovers that our commonsensical or folk conceptions of things are inadequate and so radically revises them. Our folk conceptions of space and time, for example, have undergone extremely profound revolutions, yet it is rarely claimed that space and time *do not exist* (even if there are certain avant-garde physicists willing to make precisely such a claim).[6] Rather, the claim is more often that they are not what we, and previous science, took them to be. Thus a predictable and somewhat inevitable objection to your thesis would be that, in claiming that 'no such things as selves exist in the world: Nobody ever *was* or *had* a self',[7] you are overstating your case, since your arguments only motivate a much weaker, *revisionist* position regarding the self, rather than the strong *eliminativist* one indicated by the title of your book.

---

[5] *Being No One*, op. cit., 567.

[6] See 'The View from Nowhen: An Interview with Julian Barbour', this volume.

Why, then, do you feel it is necessary to insist that selves *do not exist* rather than that they are *not what we thought they were*? Why can't we think of the project as one of revision and redefinition; of replacing our folk-psychological intuitions with the richer conceptual vocabulary provided by cognitive neuroscience; or of developing new and better-informed intuitions which are grounded in science? Can you say more about the ontological constraints that necessitate eliminating rather than revising the idea of 'the self' and replacing it with the theoretical entity you call the 'phenomenal self-model'?

TM: A lot of very good questions, for many of which I do not have a ready-made, official answer. First, if it makes you feel better (it will), to be a revisionist and come up with some weaker notion of selfhood, fine. The title of the book *Being No One* attempted to allude to many different things at the same time, and certainly wasn't about the rather trivial and unoriginal point that the self is not a substance – Hume said that, Kant said that, Buddhist philosophy of mind had made the point long before, and few people uphold this ontological claim today. Yet, for the purposes of scientific psychology and neuroscience we can certainly do without the ontological commitment to 'a' self.

---

[7] *Being No One*, op. cit., 1.

I do claim that everything we want to understand can be understood at the representational, functional, and dynamicist levels of description – and this really is not too breathtaking a point either, at least in my own view. The concept of ‘a’ self just is not a necessary ingredient of explanatory theories. We can predict what we want to predict and achieve the growth of knowledge we want to achieve with a more parsimonious conceptual framework. For example, relative to our interests and a given context, ‘self’ can be substituted by simpler notions like ‘PSM’ (phenomenal self-model), ‘SMT-system’ (self-model theory), or ‘MPS’ (minimal phenomenal selfhood).[8] In other contexts, such as literature, art, or everyday communication, we may continue to use the notion of ‘self’ in order to drive and shape each other’s mental models of reality in a way that we find attractive.

But since selfhood ultimately is a form of phenomenal content, we must take the phenomenology seriously – and the phenomenology *is* Cartesian; it is expressed by what I have called the ‘substantiality intuition’: We actually *do* experience ourselves as ontologically autonomous, indivisible entities, as something that can ‘hold itself in existence’ all by itself, and as something that *knows* about its own existence, with certainty, because in some hard to understand way it is ‘infinitely close to itself’. If we simply take the deflationary attitude again, or try to be good citizens and not exaggerate things too much by saying that, for example, this is just a straw man fallacy and then proposing some weaker notion of the phenomenal self, then we overlook the fact that the *phenomenology* itself is deeply substantialist. Of course, the phenomenology of substantial selfhood is not an epistemically justified claim, it is just a naturally evolved form of phenomenal content. But it must be taken seriously, as I have tried to do. Deflationary accounts cannot do that: Phenomenal selves are not particulars, simples, or individual entities, but dynamical processes, creating locally supervening forms of conscious content.

---

[8] See O. Blanke and T. Metzinger, ‘Full-Body Illusions and Minimal Phenomenal Selfhood’, forthcoming in the January 2009 issue of *Trends in Cognitive Sciences.*

C: Clearly, you are not simply reiterating the now familiar claim that the self is not a substance: as you point out, Hume, Kant, Nietzsche, and even Buddhism had already taught us that. Many philosophers, including critics of your views like Dan Zahavi,[9] are perfectly willing to concede this, but only in order to conclude that the self is a *process* rather than a substance. And it precisely by redefining the self as a process that one avoids the stronger (and rather more interesting) thesis that there are no such things as selves. Yet it seems clear that you cannot be content with such a redefinition. Were *Being No One* merely proposing to redefine phenomenal selves as dynamical processes, this would be just a redescription, not grounds for elimination. Rather, your argument would seem to be that the self experienced at the level of phenomenal content is an *effect* generated by non-phenomenal, sub-personal representational processes. Consequently, the self cannot be identified with these processes themselves, since that would be to conflate content at the level of the *representandum* with its *representatum*. This would be why it is no more legitimate to redefine the self as a 'process' than it was to call it a 'substance'. Would you agree that this is what distinguishes your thesis from the more familiar 'self-as-process' thesis favored by many?

---

[9] See D. Zahavi, 'Being Someone', in *Psyche* 11 (5), 2005.

TM: My perception is that some who now jump onto the 'self-as-process' reading (which I offered myself in the very first paragraph of *Being No One*) perhaps only do so because this wording has a trendy 'narrative' ring to it – and this, in turn, would set the stage for more of what my excellent British PhD student (who is a bit chaotic, but from whom I learn a lot) has recently termed 'Continental Jazz'. (I now use this new technical term all the time!) But there is no narrator, just selfless dynamical self-organization, and if the self *is* a process, then the least we must admit is that it is a very intermittent, patchy one – it comes to an end every night, in dreamless deep sleep. And waking up is obviously not performed by some transcendental technician of subjectivity pushing a magical reboot button in our brain – there is no subpersonal 'narrator' or 'author' piloting the conscious self. But it is also true that we do need good, modern neurophenomenology providing us with new conceptual instruments; a phenomenology that is not driven solely by ideological anti-reductionist resentment, but one that is at once historically and empirically well-informed. This is an extremely demanding challenge.

But I am guilty of having indulged in 'process' talk as well. A process is a chain of events, and, roughly, events are property instantiations in some given domain, at a specific location in space and time. As long as we stay with the representational level of description, we may differentiate between the representational content of such a process (an abstract property), its carrier (concrete neural dynamics), and the phenomenal properties co-instantiated along with it (Shoemaker and others would say phenomenal 'character' here, I mostly say 'phenomenal content' in order to distinguish it from intentional content per se). 'Selfhood' is precisely such a phenomenal property. But please note that even the vehicle/content distinction is not a necessary one, because it depends on your chosen theory of mental representation. More empirically-plausible ones, like the connectionist model of representation, demonstrate how the content can be *directly* realized in the physics of the carrier – for example in the sheer synaptic connection strength between individual units. It is the connectivity itself that does the job, and we have a host of formal tools to pick out the abstract properties we are interested in – partitions of activation vector space, points in weight space, trajectories, and so on. My own position is that introspectively available phenomenal content is just a very small subset of the overall intentional or representational content systems like ourselves generate and use, namely that portion which is locally determined, because it depends on microfunctional properties realized by the NCC (neural correlate of consciousness). Consciousness is in the brain, but a lot of cognition certainly isn't – and if you don't believe that, you should read Andy Clark's new book *Supersizing the Mind*.[10]

In the new TICS paper, Olaf Blanke and myself,[11] based on our own experimental work attempting to create out-of-body experiences in healthy individuals, have presented a framework for the *simplest* form of conscious selfhood. Self-consciousness is in the brain, a lot of self-related cognition certainly isn't. In particular, agency is not a necessary condition for conscious selfhood, but self-location in time (presence), self-location in space (embodiment), and identification (with the transparent content of a body-image) seem to be the three decisive dimensions. So if I speak of a 'process' I envision an intermittent neural dynamics that can sometimes instantiate and functionally integrate phenomenal properties of this kind. The existence of content does not, of course, imply that there is *reference* as well. The subjective aspect of substantiality in this representational process could be entirely misrepresentational, a form whose *character* is entirely phenomenal.

---

[10] A. Clark, *Supersizing the Mind: Embodiment, Action and Cognitive Extension* (Oxford: Oxford University Press, 2008).

[11] See note 8 above.

C: The Cartesian 'substantiality intuition' regarding selfhood which you have mentioned – rooted as it is, as you say, deep in the evolutionary past of our species, and forming the very content of our understanding of who we are and our place in the world – is certainly not one which is likely to be abandoned any time soon. Indeed, as we've already mentioned, it is extremely difficult to imagine how the idea that what people pre-reflectively take to be their innermost 'self' is in fact nothing other than a kind of ongoing phenomenal hallucination generated by their brains could ever take root at an intuitive level. Broadly similar ideas which were afloat in the psychophysiology and philosophy of the mid-to-late nineteenth century were compared by Friedrich Albert Lange to the impact of the Copernican revolution in astronomy: Just as it was once amazingly difficult for people to think of this fixed earth on which we stand, 'the prototype of rest and stability', as moving, so it would be all the more difficult for them to recognise their own phenomenal selves, 'the prototype of all reality for them', as 'a mere scheme of representation' generated by what Lange called their 'psycho-physiological organisation'.[12] In this regard, you have written that neuroscience may instigate a revolution in our self-conception more radical than any previous scientific revolution, a revolution which might have 'greater social and cultural ramifications than any previous theoretical upheaval'.[13] Could you explain what kind of upheaval you have in mind here? How do you envisage such a cultural and social upheaval given that, as you also insist, your self-model theory of subjectivity is constitutively indigestible for us at any intuitive level of lived experience, and so necessarily confined to the level of the philosopher's conceptual understanding? What conditions would need to be in place for this 'cultural integration'[14] of your thesis to take place?

TM: Again, a lot of very important questions, and I have tried to address some of them in a forthcoming non-academic book, *The Ego-Tunnel: The Science of the Mind and the Myth of the Self*.[15] To cut a *very* long story short, neuroscience turns into neurotechnology, neurotechnology turns into phenotechnology, and in the course of the next fifty to two hundred years such phenotechnologies will gradually invade our *Lebenswelt*, or 'life-world'. Even given a culture of denial this may then actually have a lot of psychosocial consequences – which, however, are very hard to foresee today. We see the very first, early developments in neurotechnology today – cognitive enhancers such as modafinil,[16] forensic neurotechnologies like brain-fingerprinting, and new types of lie detectors, or the development of new brain-machine interfaces, as in the case of the monkeys at Duke University controlling humanoid robots in Japan via the internet,[17] and so on. A small subset of these new technologies is already used to directly control information flow within the NCC itself, for example by alleviating severe, treatment-resistant depression through direct deep brain stimulation with electrodes and so on.[18] My point is that a small fraction of neurotechnology will slowly turn into consciousness technology and that *this* may have cultural consequences, even if we haven't got the proper, comprehensive theory of the human mind yet. The ethically relevant class of actions could be defined as all those forms of practical intentionality in which the content-specifier consists of satisfaction conditions centrally involving phenomenal contents. Now, more and more actions become technologically available, which directly influence information flow in the NCC and directly determine phenomenal content. I'm sure many people will have heard about the full-body illusion experiments carried out in Lausanne by Bigna Lenggenhager, Tej Tadi, Olaf Blanke and myself,[19] and perhaps some have heard about Henrik Ehrsson's brand-new variation of his own earlier studies in which you actually have the conscious experience of shaking your own hand in cyberspace.[20] What if it actually became feasible to directly control an artificial body-model in VR with your brain *and* to fully identify with the avatar on the phenomenological level (a possibility the self-model theory predicts)? Many might spontaneously say this would be terribly 'cool' or 'awesome' – but for my part, I am not so sure. If one really tries to think through, in a more sober and critical fashion, some of the consciousness technologies that are now on the horizon, one finds that the challenges they present are not only ethical, but perhaps also challenges to our mental health.

TM: I just wanted to try something new. *Being No One* was my third monograph. I had also done service for the scientific community by editing two or three anthologies focused on consciousness and by helping to construct an academic society (the Association for the Scientific Study of Consciousness),[21] setting up an infrastructure for consciousness research. So I thought it could perhaps be interesting to move on from research to teaching and the public understanding of science, at least on the level of books. So I began working on a three-volume text-book called *Grundkurs Philosophie des Geistes* (a basic course in philosophy of mind covering mostly the second half of the twentieth century, which will eventually appear in an English version as well). I am now working on Volume 3, which is on intentionality and mental representation and scheduled for publication in summer 2009. Volume One, on phenomenal consciousness, and Volume Two, on the mind-body problem, already appeared in 2006 and 2007 respectively. *The Ego Tunnel* has the subtitle 'The Science of the Mind and the Myth of the Self'. It is a popular book which will appear in March 2009. It addresses a wider audience, has a playful and experimental character to it, and attempts to explain an entirely idiosyncratic selection of those issues I personally judge to be most important in what I call the ongoing 'consciousness revolution', to the educated layperson. Of course, there is a quite a bit on self-models in there, with many concrete examples, and three interviews with prominent neuroscientists as well. The two final chapters address some of the consequences of these new scientific insights into the nature of the conscious mind-brain: the ethical challenges they pose and the social and cultural changes they may produce, given the naturalistic turn in the image of humankind. I close by arguing that ultimately we will need a new 'ethics of consciousness'. If we arrive at a comprehensive theory of consciousness, and if we develop ever more sophisticated tools to alter the contents of subjective experience, we will have to think hard about what a *good* state of consciousness is. So yes, as you say, one of the functions of this project could be to draw the attention of a wider public to the relevance of neuroethics and *normative* issues that have been neglected. (Another ethical question with which I am deeply concerned these days is whether or not I should stop writing books now!)

---

[21] See http://assc.caltech.edu.

C: In his 'Empiricism and the Philosophy of Mind' Wilfrid Sellars suggests that eliminativist claims such as the claim that 'physical objects are not coloured' ought to be construed not as statements *within* the framework of common sense or the manifest image, but rather as *challenges to the framework itself*.[22] Accordingly, is your claim that selves do not exist meant to be construed as part and parcel of a broader challenge to the manifest image, and if so, what else might need to be eliminated from it? After all, it would seem strange to say that it is only our folk conception of human beings as persons that is false; that beliefs and desires and selves do not exist but that the things about which we say we have beliefs and desires are adequately captured by common sense. So if we envision a future in which we employ the language of cognitive neuroscience rather than folk psychology, wouldn't this have to be part and parcel of a much broader overhauling of all our other folk conceptions such as our intuitive or commonsensical folk physics, folk biology, etc.?

---

[22] Wilfred Sellars, *Science, Perception and Reality* (Atascadero, California: Ridgeview, 1963), 172-73.

TM: Let me first give a 'Continental Jazz' type of answer to this question: Folk psychology is not only a theory, but also a practice. A lot of things will happen in science and philosophy, but the question of course is how this will actually change the practice, what it will do to everyday social interactions for example. As I pointed out above, although the way we speak about ourselves may only change slowly and gradually, the more likely prediction is that new *technologies* will invade our life-world and have an impact on the way we look at ourselves – because they directly change social interactions. The 'manifest image' is anchored in the phenomenal model of reality that evolved in our brains over millions of years, and it will certainly prove to be quite robust, at least in its transparent sensory and motor partitions. Social emotions and the opaque cognitive layers in our self-model, however, may prove to be more sensitive to a new cultural context. Actually folk psychology – understood as a pre-theoretical set of conceptual assumptions about reality – has already been completely demolished, just like folk physics. What will prove to be more robust is the pre-linguistic phenomenal model of reality anchored in our brains. And, functionally speaking, this is predominantly what drives our behaviour.

There is a deeper aspect to your question, however: it pertains to the 'self-as-epistemic-subject'. What many do not see is that there is also a sort of 'folk epistemology' – a deeply engrained, naturally evolved set of assumptions about what it means to know, what certainty is, how we mentally represent the world. If cognitive neuroscience also dissolves our traditional ideas about what a knowing self – an 'epistemic agent' – is, then this might also eventually have interesting consequences for the theory of science and philosophical epistemology.

C: Do you foresee an increasing resistance to your attempt to integrate philosophy and neuroscience, given philosophy's institutional complicity with servicing socio-cultural interests (morality, religion, liberal-democratic consensus, etc.)? What scope might there be for the kind of radically revisionary philosophical naturalism to which you are committed given how energetically some professional philosophers insist on providing alibis for folk superstition? Is the human race doomed to eternal resistance to such difficult and uncomfortable scientific truths? Or is such 'difficulty' simply based upon a misconception as to what theses like yours entail? What sort of cultural effects might we expect were they to be integrated into our everyday understanding of the world?

TM: A sincere sensitivity to ethical issues, a commitment to liberalism and democracy – if taken seriously – are very radical affairs, not something old-fashioned, and if philosophical conservatism (you may be disappointed to hear) means keeping such sociocultural interest alive then we certainly need good, professional, analytical philosophy to do this. The overall situation on our planet reminds me of one big ocean of irrationality, suffering and confusion – if more conservative philosophy's 'complicity' with certain social institutions can help at least a little bit to improve our situation, then this is a good thing.

I think, taken as a whole, humankind will prove to be absolutely robust in its resistance against the growth of knowledge, against what I sometimes like to call the 'Enlightenment 2.0' introduced by modern philosophy of mind and cognitive neuroscience, AI and AL, etc. There may be some rare individuals or even groups who find an interesting new synthesis of intellectual honesty and spirituality. But on a larger scale I believe two types of reactions are most likely to spread: A primitive form of hedonism, based on vulgar forms of materialism and a cynical, simplistic version of normative neuroanthropology; and the rise of irrationalism and fundamentalism, even in secular societies, supported by all those who desperately seek emotional security and espouse closed worldviews, simply because they cannot bear the naturalistic turn in the image of humankind. Both types of reaction are deeply human, and obviously, both are a danger to the very few stable, open societies we have established on this planet so far.

C: We certainly don't intend to denigrate the value of hard-won civil liberties or the democratic ethos: a sincere sensitivity to ethical issues and a commitment to democracy are indeed very grave and important matters, and certainly in no way 'old-fashioned'. But the question remains whether social institutions shaped by a conception of human beings as maximally rational, self-determining agents –

a conception with deep ties to a philosophical tradition that construes ‘selfhood’ as the defining feature of properly human being or ‘personhood’ – will prove adequate to the challenge of improving a human condition characterized by the undeniable surfeit of what you yourself describe as ‘irrationality, suffering, and confusion’. Might there not be a fundamental difficulty in reconciling the naturalistic understanding of selfhood as an inevitable ‘user-illusion’ generated by the human organism with a commitment to the irreducible worth of persons understood as the ultimate loci for the freedom and dignity attributed to the individual? Does the notion of ‘selfhood’, given its close ties to the concept of ‘personhood’, not serve to anchor the ethical, political, and juridical norms upheld by those who espouse liberalism and democracy? Can one really retain these norms while denying the existence of the ‘selves’ that were supposed to feature among the necessary conditions for human personhood and serve as the bearers of freedom and dignity? Can there be persons without selves?

TM: Persons are not something we find out there, in objective reality. Persons are *constituted* in societies – through mutual acts of, say, acknowledging each other as rational and morally sensitive individuals. There can be selfless persons. Selfless individuals could certainly acknowledge each other as rational, and agree on a basic political and moral consensus. The problem is rather that we may turn out to be less rational than we thought, and less self-determining (whatever this might mean exactly) than our own previous anthropological self-idealizations have encouraged us to believe. My point is that (if this unargued empirical speculation turns out to be true) it would be irrational as well as unethical in itself if we didn't take such new empirical insights into account. But will we be rational and ethical enough to let new data about the evolutionary history and the neural underpinnings of rational thought and moral cognition themselves influence decision-making, say, in pedagogy or politics?

I think you make a very good, and relevant, observation in describing why many of our best political theorists assume they *must* resist a naturalization of selfhood: They see the danger of bulldozing the normative dimension of personhood, of losing the 'critical subject'; the dangers associated with an erosion of precisely what you call the 'anchor' of our ethical, political, and juridical norms. You cannot imagine how well I know these worries and anti-reductionist resentments! When I studied philosophy at Frankfurt in the late 1970s, it was not only trendy, but a frequently repeated and politically-correct commonplace move among we students to call the kind of stuff I and others do today 'proto-fascist'. I was part of the more radical wings of the alternative movement of the late 70s, and when I sat in the seminars of Jürgen Habermas and so on all of this was certainly too superficial and not radical enough for me – at that time I thought that if you were really *serious* about getting in touch with political reality then you could do this by smelling some tear-gas, or by *actually* walking through shanty-towns in India. I certainly do respect Habermas and old-school political philosophy, but I have always thought that one has to dig *much* deeper in order to understand not only how the German catastrophe could happen, but why we seem unable to end all this violence and oppression, the constant turmoil on our planet that we call our 'history'. I think it is a kind of intellectual tragedy that most of the best political philosophy is systematically shielding itself off from neuroscience, evolutionary psychology, and so on. It does damage to our discipline.

C: This obdurate refusal on the part of most political philosophers to acknowledge any possible connection between the normative and the neurophysiological is indeed a kind of intellectual tragedy. But tragedy also veers into farce, as when the veritable phobia towards 'scientism' and 'reductionism' exhibited by Frankfurt School Critical Theory leads its adherents to issue moralistic denunciations of science and technology which are virtually indistinguishable from those of institutions like the Catholic Church. But critical theorists are certainly not alone in this regard. Returning to your earlier comments about analytic philosophy: We share your admiration for the analytic tradition's commitment to intellectual sobriety, responsibility, and rigour. However, despite these virtues, it cannot be wholly absolved from responsibility for the kind of neo-scholastic 'intuition-mongering' critically invoked at the beginning of this interview. Thus we are less convinced that this tradition is entirely innocent when it comes to promulgating the kind of 'closed worldviews' which actively obstruct the growth of natural-scientific knowledge. While twentieth-century analytic philosophy may have started out in part, as you put it, as 'a beautiful rebellion against academic pretentiousness and narcissist obscurantism', once should not forget that it was also in many cases an avowedly *anti-naturalist* rebellion bent on preserving the autonomy and 'purity' of philosophy by actively preventing its hybridization with empirical disciplines such as experimental psychology (a story minutely documented in Martin Kusch's *Psychologism: A Case Study in the Sociology of Philosophical Knowledge*).[23] Indeed, one might argue that the active resistance on the part of many academic philosophers to any miscegenation of philosophy with the empirical sciences ultimately has the unfortunate effect of helping to make the world safe for the irrationalism and fundamentalism of those who, as you put it, 'cannot bear the naturalistic turn in the image of humankind'. In this regard, your use of the expression 'Enlightenment 2.0' is particularly suggestive: could you elaborate? Are you referring to the way in which the techniques and methods of the natural sciences are now being used to explore those phenomena which we take to constitute the core of our humanity, i.e. mind and consciousness? The emergence of a 'science of cognition' would seem to represent science's attempt to understand itself by investigating the structure of the mind engaged in investigating reality. Is this the ultimate twist in the trajectory of Enlightenment: the twist whereby the explanatory strategies hitherto used to disenchant 'outer nature' are now being deployed to disenchant our own 'inner nature'?

TM: Well, first, anti-naturalism could be true. We have to take one philosopher and one argument at a time. I certainly do understand your point – academic disciplines are self-modeling entities too, and they tend to preserve their boundaries. There will always be individuals who profit from isolationism, from keeping the boundaries hard and the methods 'pure'. There is this conservative social movement within analytical philosophy, yes. But let us not commit a psychologistic fallacy or indulge in paranoia – I do not know any anti-naturalists who *intend* to make the world safe for the irrationalism and fundamentalism. The question is simply who is right here.

---

[23] New York and London: Routledge, 1995.

Enlightenment 2.0 will tell us more about what the conditions of possibility for knowledge are. We will use our intelligence not only in order to understand its own evolution, but also to begin to optimize it. We will use scientific rationality to gradually understand the fine-grained, microfunctional properties realized by our brains that *enabled* scientific rationality in the first place. If one takes a closer look, it is unclear what 'Enlightenment 1.0' actually was, but at least there were certain general *attitudes* increasingly shared and cultivated in Western society – a critical questioning of traditional institutions, customs, morals, and so on. I think that in the decades to come we may be able to elevate this old philosophical project to a new level of precision and generate a sustainable growth of knowledge by connecting it to our new partner disciplines like cognitive neuroscience. In particular, we could free the Enlightenment project of the accusatory, moralizing tone it has tended to exhibit in the past – we may obtain a better understanding of the ways in which in-group behaviour, tribalism, traditionalism, unargued conservativism, higher-order forms of self-deception and cultures of denial actually evolved, what their neural underpinnings are, why they proved to be adaptive in the world of our ancestors and how they now spill over into the process of doing science.

We may also come to understand how this effect could be minimized. In the course of this process we will also see that actual scientific practice is not at all something carried out by philosophical saints pursuing the ideal of self-knowledge, but is often driven by jealousy, ill-will, ostentatious behavior and brute career interest. This could indirectly bring about a great improvement in the process itself; it could serve to foster intellectual honesty. But Enlightenment 2.0 may also have a sobering quality about it, extending Max Weber's 'disenchantment of the world' to the conscious self. We will have to pay an emotional price for it – and what I am interested in is what this may do to the forces of social cohesion, to what Habermas would have called *soziale Bindekräfte*.

C: In *Being No One*, you describe the object which I consciously experience as holding in my hand as 'a dynamic, low-dimensional shadow of the actual physical object in your hand, a dancing shadow in your nervous system'.[24] Does this not also imply that the hands which are holding the book, and indeed, the entire manifest image of the world, turns out to be 'a dancing shadow in my nervous system'? There are several other places in your book where you say that the content of our phenomenal image of the world is 'solely' and 'exclusively' due to our neurophysiology. For example, you write: 'Our conscious model of reality is subterranean in that it is *determined exclusively by the internal properties of our nervous system* [...] phenomenal experience as such unfolds in an *internal* space, in a space quite distinct from the world described by ordinary physics [...] [and] evolves within an individual model of reality, in an individual organism's brain, and its experiential properties are *determined exclusively by properties within this brain*'.[25] Similarly, the cognitive scientist Donald Hoffman has argued that our perceptions of the world no more resemble the world itself than a computer icon resembles the inside of a computer.[26] Would it be fair to say that, for you, representation is more akin to simulation, understood as the process whereby the mind-brain *generates* its own virtual phenomenal reality, than to replication, understood as the process whereby a mirror *reflects* a pre-existing reality? But then what is the ontological status of the reality that is being perceived or simulated? Moreover, how do we get to know about the non-phenomenal objects to which the phenomenal 'shadow-objects' of our experience supposedly correspond in some way, and what is the nature of this correspondence? Does your conception of representation allow for the possibility that our perceptions might resemble aspects of the unperceived world in some sense, at least at a structural level? Or does the world generated by representational processes, the world of commonsense phenomenal experience, screen us from the world in itself? We might be tempted to insist that the only real objects are those quantified over by fundamental physics, but the problem with this is that fundamental physics nowadays doesn't quantify over *any* objects (a point made by James

Ladyman in another interview for this volume),[27] and certainly doesn't provide us with anything like the 'actual physical objects' experienced in phenomenal consciousness. How, then, is science, which would seem to be rooted in the domain of phenomenal experience at some level, able to access reality? Can science dispense with appeals to perceptual consciousness altogether? Where do you stand on these basic epistemological issues?

TM: Well, we should never conflate intentional and phenomenal content. Conscious experience *per se* is how the world *appears* to you – that is all. Epistemology only comes in with intentionality, with semantic properties of representations, such as reference or truth. Unfortunately I don't know Ladyman's work yet, but it seems obvious to me that he has a very good point – we have to assume those entities as existing that our best current theories with the highest predictive success etc. *need* to postulate, and classical objects will not be among them. I like to look at our phenomenal model of reality – including objects, properties, relations, naïve physics and all – as a multimodal interface to navigate our behavioural space, a tool enabling the organism to successfully close certain sensorimotor causal loops on a very coarse-grained level, shielding it from the underlying causal complexity. Consciousness is autoregulation in a system that has become much too complex to understand itself. The phenomenal model of reality is a naturally evolved virtual organ, and segmented scenes, sets of properties bound into robust objects, and so on, were functionally adequate fictions – just as selves were. But the majority of these fictions *must* have picked out at least some of the relevant causal regularities governing 'middle-sized' physical phenomena in our space of interaction, or else they would not have helped us to copy genes more efficiently. Other virtual models may have been adaptive precisely *because* they created functionally adequate forms of self-deception. But given the evolutionary history of nervous systems as a background assumption, it is hard to see how the majority of relational/structural assumptions about our ecological niche could have been outright false – our ancestors would not have survived.

---

[27] See 'Who's Afraid of Scientism? Interview with James Ladyman' (this volume), and James Ladyman and Don Ross with David Spurrett and John Collier, *Every Thing Must Go: Metaphysics Naturalized* (Oxford: Oxford University Press, 2007).

You may remember that in *Being No One* I explicitly and deliberately decided not to develop a theory of mental representation, and to ignore epistemological issues in favor of fine-grained neurophenomenology. But I did – very vaguely and perhaps inconsistently – endorse connectionism, embodied dynamicist cognitive science and Johnson-Laird's theory of mental models as working background assumptions. For a mental model, the key phrase you are looking for could be 'partial relational homomorphy' – perhaps it is like a child's colouring-book: an extremely selective set of outlines is given, but all the colours are self-made. The extremely small and selective set of spatiotemporal relations and causal regularities faithfully carried over into our perceptual model of reality might then be something that is strongly relative to our bodies and the actions beings like us can perform in the world – a world without objects or selves, but one that can be known through the right combination of science and philosophy.

Alien Science

Interview with Jack Cohen and Ian Stewart

One of the most fertile collaborations in contemporary popular science writing began with a biologist and a mathematician meeting for lunch at a Coventry pub in 1990. Combining their prodigious knowledge of contemporary science, the unique partnership between Jack Cohen and Ian Stewart has spawned a series of popular science books remarkable in their scope, epistemological subtlety and conceptual innovativeness. To read 'Jack&Ian' is to embark upon an exhilarating and intellectually enriching ride through the thickets of contemporary scientific thinking and emerge with a profound sense of how it all interconnects. Their combined critical perspective brings much-needed clarity to popular science memes such as 'emergence', 'chaos' and 'complex systems', and they can be relied upon never to neglect the 'big picture'. In our interview, Cohen and Stewart recount the history of their 'complicit' collaboration, discuss the significance of the novel ideas proposed in their co-authored works, explain their criticisms of reductionism, anthropic reasoning and astrobiology, and tell us about the aliens who helped them to write their books.

Collapse: Perhaps a good place to begin would be with one of the key conceptual innovations of your work together, namely 'complicity', which you define in the opening pages of your first major co-authored work, *The Collapse of Chaos*,[1] as 'the tendency of interacting systems to co-evolve in a manner that changes both, leading to a growth of complexity from simple beginnings – complexity that is unpredictable in detail, but whose general course is comprehensible and foreseeable'. The same concept is introduced more succinctly in *What Does a Martian Look Like?*[2] as referring to 'any process by which two different systems recursively complicate each other by repeated interaction'. Perhaps you could say a few words about the simple beginnings and co-evolution of what you have described as 'the collective entity [...] Jack&Ian'?[3] When and how did this unique collaboration come about, and what are some of the ways you have 'recursively complicated' each other over the years of your repeated interaction?

Ian Stewart: Jack and I met in 1990. He had read my book *Does God Play Dice?*,[4] and some of my SF stories, and sensed a fellow spirit. He phoned me, we met in a pub for lunch, and we were still there at about half past five, discussing various areas of science. We continued to meet about once a week for several years, and out of those discussions emerged the plan for a book: *The Collapse of Chaos*. One of the first questions Jack asked was 'what's a good word for two processes interacting but modifying each other recursively, so that they end up being completely different from anything you'd expect just by putting them together?'. At the time, I had no idea.

[3] *What Does a Martian look Like?*, op. cit., xii.

[4] Ian Stewart, *Does God Play Dice? The Mathematics of Chaos* (Oxford: Blackwell, 1989).

JACK COHEN: I'd been very caught-up in this issue, looking for a vocabulary for interaction with change in both sides, having in mind nature/nurture etc., specifically for embryology (a book on reproduction was in preparation); asking actors (e.g. Ken Campbell – recently deceased alas) what words they used for audience relations: when actor comes on stage, audience changes; seeing that change, actor reacts. 'Well, yes', they said, 'that's so of course – but we don't have words for it ... !'. I was also doing the 'Cell Biology' chapter for a great tome in *Obstetrics & Gynaecology* and, having done a drawing of a lot of the reactions in 'the cell', had come to the conclusion that it would all knot up, there was no way that these reactions could 'proceed'. There was something in *Does God Play Dice?*, which I'd just read, that suggested that Ian could be of help, so I rang him. We arranged to have lunch in the Coventry Cross pub the next day.

IS: During the writing of *The Collapse of Chaos*, I was playing word-games with 'simplicity' and 'complexity', as part of an attempt to characterise how simple large-scale structures and behaviours can emerge from the interaction of large numbers of simple components, and the words 'simplexity' and 'complicity' presented themselves. Of course 'complicity' is a standard word, but what it means has strong echoes of Jack's question about recursive interactions between two systems. So we decided to give it a more technical meaning, in the context of complex systems.

By the time we wrote *What Does a Martian Look Like?* we had become used to employing the word, so we explained it in the simplest terms we could think of to avoid importing too much baggage from complex systems.

Jack&Ian is itself an example of complicity. We have similar attitudes in many ways, but very different backgrounds. In particular Jack is a biologist and I'm a mathematician, and in those days the two subjects tended to see eyeball to eyeball rather than eye to eye. But we discovered that most of the generic questions (such as 'how do you stop PhD students spending their time on tedious routine work and get them to start thinking about the problems?') were common to both subjects. As we explored the common issues, we found that the combination of viewpoints often led us in directions that neither of us would have thought of on our own. The concept of 'complicity' was one example. It very much felt as though there was a combined entity which somehow knew more than both of us did put together. To distinguish our individual ideas from the joint ones, we referred to 'Jack&Ian'.

JC: The Jack&Ian viewpoint(s) was a curious mix: Ian was very divergent (consistent with the chaotic viewpoint: the space between the piano-keys increases, and you get more keys etc.) and I was very convergent (the egg splits, but you don't get two half-embryos – each 'heals' and becomes a complete embryo!). The first paper we did together, which was called 'Chaos, Contingency and Convergence',[5] exposed this difference amusingly, and laid the foundation for *The Collapse of Chaos*, in many ways.

C: One of the most striking aspects of your collaborative works is the impression one receives of a genuinely creative symbiosis of ideas originating from widely disparate fields of inquiry. While one can of course at times identify certain concepts and themes as bearing the signature of either 'JC' or 'IS', the way in which they then come together and re-emerge, reciprocally transformed as it were, in your co-authored writings, is something remarkable indeed. Would you care to comment upon the collaborative process which goes into writing your books?

IS: We even make such identifications ourselves, on occasions when one of us has a particular viewpoint and the other isn't sure. So we kind of sense when we are in JC and IS mode, and when it's Jack&Ian.

How we work depends on the book. *The Collapse of Chaos* and *Figments of Reality*[6] were both written the same way. We talked a lot, about whatever came to mind. We took rather scrappy notes. As the ideas came together, Jack would put together a plan.

---

[5] *Nonlinear Science Today*, 1991: 9-13.

[6] Jack Cohen & Ian Stewart, *Figments of Reality: The Evolution of the Curious Mind* (Cambridge: Cambridge University Press, 1997).

JC: Only about a sentence or two for each chapter ...

IS: After I'd commented on the plan, he fleshed each chapter heading out into about four pages of notes. Then I expanded them to chapter length, usually rewriting heavily, putting in anything related that seemed to fit, marking gaps for later repair ('Jack: tell me more about ampulla of Lorenzini'), making suggestions ('Would it be worth referring to Schrödinger's cat here?'). Jack would return the manuscript covered in pencilled responses and comments, and we'd go round the same procedure several times. On the whole we did this chapter by chapter, so I might be polishing one while Jack was tearing another to bits. As it began to converge, we took a broader view, did an editorial job on each other's contributions, chucked stuff out, replaced it with something we thought was better.

JC: A lot of this involved quite deep argument. I think there were times when the question 'How could I ever have thought that we could work together?' occurred to both of us. But then we just had to get Jack&Ian to sort out the problem, or – occasionally – we'd just leave both views in.

IS: Some stuff was self-indulgent – notably the Zarathustrans, a race of aliens with a group mind – but they were there for a reason. Their role was to jog us, and our readers, out of the safe, familiar, parochial way of thinking. Sometimes the Zarathustrans illuminated things for us, too. I'd write a sentence, look at it, and ask myself 'now what would the Zarathustrans say about that?' And sometimes they'd say it was rubbish, and I'd work out what their viewpoint would lead to, and occasionally that made more sense than what I'd written. I think many authors find that their characters sometimes take over the book – not in reality, they're inventions, but in imposing a kind of consistency. 'Would my character do/say that?' And sometimes the answer changes your mind.

Our science fiction novels *Wheelers*[7] and *Heaven*[8] followed a very different pattern. We plotted *Wheelers* on a boring car journey from Coventry to Plymouth, and then I scrambled to write it all down on hotel stationery. Then Jack's agent sold it. Then we wrote it. Jack invented most of the characters, ideas, background, and plot. I wrote virtually every word. We did much the same for *Heaven* (not our choice of title and possibly a mistake) except for the original plot, which we assembled over several weeks. We plotted out a prequel, *Oracle*, during a very uneventful book-signing (the shop hadn't advertised it until the morning of the event). We're still looking for a publisher, though.

The *Science of Discworld*[9] series with Terry Pratchett was written differently again, as befits a three-person collaboration, but I won't go into details.

C: *The Collapse of Chaos: Discovering Simplicity in a Complex World* was published in 1994, and was followed in 1997 by

Figments of Reality: The Evolution of the Curious Mind. For those of our readers who may not be familiar with your work, could you briefly explain a little more about what you set out to do in these books?

IS: *The Collapse of Chaos* was an attempt to tackle one of the big questions Jack asked as a result of reading *Does God Play Dice?*, which is about the mathematics of 'chaos' – which, by the way, isn't just another word for 'random'. The full term is 'deterministic chaos', and it reflects what I would argue is one of the most fundamental discoveries of the late twentieth century. Namely: rigid mathematical rules, in which the entire future of a system is determined by its present state, still permit behaviour so complex that it can be unpredictable, and certain features are genuinely random – that is, they can be modelled with complete rigour as stochastic processes.

Anyway, Jack wanted to know how a complicated system like a biological organism could exist as a coherent working structure when 'everything is chaotic'. Part of the answer is that the mathematics tells us chaos is possible, indeed common, but that it is not ubiquitous. Non-chaotic deterministic systems also exist. But the deeper issue is how chaotic systems can have robust features, as if the chaos somehow 'collapses' – hence our title. In retrospect it may not have been a good choice: people sometimes think the book is an argument against 'chaos theory', which it absolutely is not.

What we concluded – and I'm not claiming this is either correct or the last word – is that robust patterns not only can, but typically do, emerge from complex interacting systems. Down on the level of fine detail, nothing makes sense.

JC: This was my stuff with cell processes again. 'Nothing makes sense', says Ian, but it works, so far as we can tell, totally reliably. So, at the level of the cell, we're not in a 'soup' of chemicals dissolved in water; we have proteins all hooked up to each other, systems of membranes all interleaved, an immensely complicated network of causality that simply isn't a watery solution. I've done a lot of EM (electron microscopy) of cells, and quite a lot of time-lapse photography. The two views – EM revealing a series of 'rigid' membranes, time-lapse photography showing fluid movement – don't make any sense with each other. The pictures you get are incommensurate, 'wave' and 'particle' – so the cell 'is' something else again, with Ian's view and mine wrapped up in it. But this is quite common – think of nerves and 'mind'!

IS: Observe a local region of neurons firing in a brain, and you won't be able to tell what it's thinking – or even *that* it's thinking. But on a higher level, there may well be coherent structure. And (I'm basically a determinist) it is a *consequence* of the underlying small-scale structures and rules; it doesn't transcend them in any causal way. However, there is no mathematical scheme that can derive the large-scale structure from the small-scale rules, except by simulating the entire system step by step. There are no short cuts to the patterns. Basically, this is how I like to define 'emergence' as a mathematical concept.

So *The Collapse of Chaos* was mainly about physical science and evolutionary and developmental biology. *Figments of Reality* was a kind of sequel, concentrating on the mind/brain problem. From our point of view it seemed plausible that mind is an emergent property of a brain – under suitable conditions. Separating the two and making them essentially independent, as Descartes did, misses the crucial feature of emergence: that it is *caused* by the fine-scale structure and rules, but is not something that can be *derived* from them (by an argument short enough for humans to follow). So mind is a consequence of brain structure, but it cannot be *reduced* to brain structure by any rigorous logical scheme. Our chapter on free will is an attempt to reconcile the small-scale determinism of neurons with the apparent lack of determinism in the brain's decisions. We ignored quantum indeterminacy for two reasons: it may not be as random as physicists think – it might well be deterministic chaos – and if it is genuinely random, then it doesn't explain free will anyway, because that is a directed choice, not a coin-toss. What we ended up with is very close to (and anticipated) what Daniel Dennett argues in *Freedom Evolves*.[10]

C: This is the chapter in *Figments* amusingly entitled 'We Wanted to Have a Chapter on Free Will, but We Decided not to, so Here It Is'. The conclusion you reach on the problem of free will, as pithily summarised in the final sentence of the chapter, is that while freedom is indeed an illusion of sorts, it's 'not "just" an illusion: it is a *figment*

---

[10] Daniel Dennett, *Freedom Evolves* (London: Penguin, 2004).

rendered real by the evolutionary complicity of mind and culture'.[11] Could you say a little about what this means, and how it anticipates Dennett's conclusions?

IS: We think that the brain makes *decisions* rather than *choices*. That is, when faced with various courses of action, the brain decides on one of them by some process which depends on our past history, personality, and so on. We feel as though we could make either choice, but that feeling may be just the 'quale' of deciding – just as the vivid impression of red is the quale of whatever in the physical world makes us perceive the colour red. This resolves the apparent conflict between physical laws that are either deterministic (Newtonian) or random (quantum). Neither fits the simple 'free will' model in which under identical circumstances the human brain is free to behave in several different ways. It *feels* as though it could do that, but what it actually does is constrained by the physics. However, because the brain is a complex system, it may in practice be unpredictable even if it behaves deterministically.

We don't really think others have free will. When they do unexpected things, we always wonder 'Why did they do that?' and seek excuses. Once we realise 'Oh, she's had a row with her boyfriend' we feel we understand the reason for the choice. With true free will, there doesn't *have* to be a reason.

Dennett argues his way to a very similar view, with 'free will' as the *quale* of decision-making.

---

[11] *Figments of Reality*, op. cit., 241.

JC: Dennett takes the first three chapters to show that we can't 'decide' if the universe is determinate because, essentially, of levels with causality between them – which is essentially what in *Figments* we called 'Ant Country'.

C: For those unfamiliar with your writings, what do you mean by 'Ant Country'?

JC: The Ant Country side of things refers to all the turmoil of micro-causality that underlies history, while the 'figments' level is not just aggregates but rather 'things' with emergent properties, that (seem to) react to each other on the higher level; this separates the causality into different provenances, so that 'determinism' can't be determined! Dennett, finding this essential a-causality, leaves the question of freedom of will aside; he goes on to say that the only use of this notional 'freedom' is to make the inevitable evitable. From the same indeterminacy we go for the joke in our chapter title.

IS: Ant Country is our term for the way that many localised parts of complex systems tend to be indistinguishable from each other as far as significant differences go. Rather like being somewhere randomly chosen in a big UK city: There will be a main road with shops, an Indian restaurant, a pub, a Chinese takeaway, a betting shop, a church, some side streets, ordinary houses ... a bus stop, a set of traffic lights ... the locality will have much the same stuff as any other 'non-special' locality.

The prevalence of Ant Country means that it is virtually impossible to understand what a complex system is doing by looking at the details. A computer program, for instance, will always look like 0011011011100101 ... no matter whether it is a word processor, a spreadsheet, or the computer's own operating system. So Ant Country represents a particular kind of barrier to reductionism, when considering complex systems.

JC: We called it 'Ant Country' for essentially three reasons: Firstly, Aunt Hillary in *Gödel, Escher, Bach*,[12] the anthill whose recognition of her friend the anteater works by the ants panicking; secondly, Langton's Ant game, which demonstrates that even knowing all the rules you can't predict what'll happen; and thirdly, by envisioning a kind of suburbia, an Ant Country in which all paths are equal, some leading up and some down but without any scheme. Like suburbia, the location of the odd pub and post office doesn't imply a general geography. When trying to argue across this Ant Country to explain chemistry by physics one can use the odd by-way, but there are no general rules! This is what Ian means when he says that mind is a consequence of brain, but can't be reduced to brain. Ant Country doesn't have any general rules.

C: Apart from anticipating Dennett on freedom, what you say in *Figments* about the illusory nature of selfhood and the evolutionary provenance of that illusion also strongly gestures towards ideas subsequently worked out at considerable length by Thomas Metzinger in his recent tome

---

[12] Douglas R. Hofstadter, *Gödel, Escher, Bach: An Eternal Golden Braid* (London & New York: Penguin, 1979), 311-336.

Being No One.[13] For example, you write about the difficulty of trying to explain how the brain creates the illusion of an internal observer 'to a person who has the strongest feeling that they *are* an internal observer, sitting inside their own head, *experiencing* that self-same illusion.'[14] In this respect, Metzinger describes us as self-modelling systems permanently ensconced within an evolutionarily bestowed 'naïve-realistic self-misunderstanding', a naïve realism in terms of which we constantly *confuse ourselves* with the content of our own self-models. Pushing this idea to what would seem to be its logical conclusion, Metzinger even goes on to insist that inasmuch as there is an illusion in operation here, it is quite literally *no-one's* illusion, since there is no-one there to be the *subject* of the illusion. As with the case of free will, however, I suspect that you would want to insist that the illusion of selfhood is not 'just' an illusion.

IS: I think 'illusion' is a loaded and overworked term. For example, physicists often say that the solidity of matter is an illusion because matter is mostly empty space. I'd prefer to say that the space, far from being empty, is full of inter-atomic forces, and it is this that creates the impression of solidity. Far from being an illusion, that's what 'solid' means on the atomic level.

So our *feeling* of 'self' is not illusory – we really do feel that way. But this of course doesn't imply that our naïve interpretation of what we feel is the literal truth. 'Self' is whatever causes us to feel that we *have* a self. And it must be real (whatever that means) or it wouldn't happen.

---

[13] Thomas Metzinger, *Being No One: The Self-Model Theory of Subjectivity*. MIT Press: Cambridge, Massachusetts, 2003. See also 'Enlightenment 2.0. Interview with Thomas Metzinger', this volume.

[14] *Figments of Reality*, op. cit., 205.

JC: Metzinger clearly has gone further than we did; we're clear about 'self-hood', but only in the context of the Zarathustrans, as a model for our multibrains.

C: Metzinger describes *Being No One* as 'an experiment in *interdisciplinary* philosophy',[15] and it seems to us that this could equally well serve as a description of your work together. In the Preface to *The Collapse of Chaos* you forewarn the reader that while, for the first, more orthodox and conventional half of the book, you are able to 'provide plenty of roadmaps to tell you in advance just where we want to take you', you are unable to do this for the second, more experimental and speculative part of the book, since 'where we wish to travel, there are not only no road maps, but no roads'.[16] It is perhaps in part this sense of embarking on a real intellectual adventure, a genuine experiment in thinking, which makes your work so attractive to a growing philosophical readership who find themselves becoming increasingly disillusioned with the self-enclosed and narrowly specialised nature of much of contemporary academic philosophy. Your books tackle ontological and epistemological issues by directly drawing upon the full extent of contemporary science rather than from the point of view of a priori conceptual analysis or textual hermeneutics. To those of us who have relinquished the conceit that one ought to be able to do epistemology and metaphysics without actually *knowing* anything – that is, without drawing upon the immense labours of the empirical sciences – and yet who remain dissatisfied for one reason or another with most versions of contemporary philosophical naturalism, your work thus provides a real breath of fresh air. Would you care to comment on this? How do you see your work in relation to traditional and contemporary philosophy? While your books are in no sense works of philosophy in the traditional sense, and although you rarely cite or discuss any of the great philosophers, you do speak of 'invading their spaces and reinventing their wheels'.[17] What precisely did you have in mind here?

---

[15] *Being No One*, op. cit., 2.

[16] *The Collapse of Chaos*, op. cit., 2.

IS: I think Jack and I both realised we were impinging on philosophical territory, and that we were very much amateurs (though Jack was quite widely read in philosophy – another of his roles in the collaboration). So we tried to tread a fine line in which we put forward our own ideas without explicitly relating them to mainstream philosophy, yet also without claiming that everything we said was new. We've been gratified by the way the philosophical community has responded.

The 'road-map' remark was motivated by Terry Pratchett, who read the book in manuscript form, and commented that in the first half he felt he was being pushed to the top of a roller-coaster, and was awaiting a wild ride – but the rails disappeared. We did our best to fix this problem, but we didn't want to do the usual academic trick of giving the main point away before we got to it. Sometimes suspense is better than foreknowledge.

---

[17] Ibid., 5.

I think that what we're doing is tossing out various ideas, mostly with a sound scientific pedigree, that might stimulate a few philosophers and set them thinking along fresh lines.

Contemporary philosophy is pretty much a mystery to me, except that some of it seems to embrace a rather extreme form of social relativism – that science is whatever scientists agree on, for example. Now, there is a sense in which that is true, but there is a definite mechanism involved in coming to agreement, and it involves cross-checking with the external world. Even if every scientist in the world decided that gravity pushes things up, they still wouldn't want to stand underneath a piano when someone pushed it out of a window. Someone once said that when postmodernists come into a room they always use the door. Isn't it strange that they don't just get together and agree they can walk through the walls? A lot of this stuff strikes me as pretentious and silly. It certainly misrepresents science.

I also think that there is an ever-present danger, when thinking about 'philosophy of science', to put forward rather simplistic models of how scientists work – simplistic in the sense of being too rigid and broad – and then when it turns out scientists don't do that, to argue that they are doing it wrong because they're not doing what the model says they should. (I'm pleased to see that philosophers are generally avoiding this pitfall nowadays).

Now, I'm prepared to be put right on some of this, and I'm risking letting my hair down because I think I'm among friends. And I get the impression – in part from talking to colleagues in the Philosophy Department at Warwick – that many of today's philosophers have the same misgivings.

Though I'm sure they would phrase them differently.

As for the comment about invading the spaces of the philosophers, that was partly a get-out clause, acknowledging that our ideas have all sorts of relations to things that philosophers have been saying for ages, while sidestepping the obligation to give chapter and verse. Because I, for one, wouldn't be able to give chapter and verse. Jack might do better, and maybe he can come up with a good example. Within science, a similar problem arises. Some of what we say can be seen as 'systems theory', so we ought to pay homage to Ludwig von Bertalanffy. But the books cover a huge amount of ground, and the whole area has been so widely trampled that picking our way through the undergrowth would probably create more injustices than it removed – and it would make the book pretty much unreadable. In an academic work, we'd have to sort out sources like that, but this is popular science, and the most important thing is to tell a story. However, we did say when we consciously got ideas from some specific source.

JC: I'm as annoyed by philosophical relativism as Ian is, but this is complicated by my philosophical allegiances. I started off to be a rabbi, but read Spinoza's *Ethics* at the age of sixteen or seventeen, so became a biologist instead. But I still have Jewish associations (my rabbi says I'm the best atheist in her congregation ...) and read Spinoza, very conscious of how much has been done to build on the original – and to edit lots of it out. The quasi-religious bits of *Collapse* and *Figments* – not to say anything about *Heaven* – are very naïve (though not so naïve as other scientists 'looking into the Mind of God': ouch!); but I do read *Nature* every week – all of it. Ian reads *Science* and *New Scientist*, too. So we have a very useful body of knowledge from which to extract ideas, and against which to ring our own new thoughts.

So as you say, I think this is the main difference between our work and that of most philosophers: we do have much of modern science available to us; we do actually know quite a lot! But what we know isn't (just …) the fashionable stuff, mostly quantum physics, that 'real' philosophers of science play with; we discuss between ourselves all kinds of stuff, from geology/palaeontology and embryology/*in-vitro* fertilization to quantum experiments (the philosophers don't 'get' the experiments, just the thinking!). For example, in my own field, there has been almost no 'professional' notice taken of the Waddington symposia which, from the mid-fifties up to the nineties, began to sort out the real (philosophical) problems of development-and-evolution – what's in general being ducked now under the heading of 'evo-devo'. Professional philosophers took no real notice of those symposia, or of the (admittedly rather difficult) philosophies expounded therein – even though these symposia dealt with such issues as the thalidomide disaster, and began to deal with issues like what the genome was and what it did. This stuff is coming in now under the heading of 'epigenetics', and philosophers (with the notable exception of Evelyn Fox-Keller) are still bemused by it. It's desperately important stuff, but it's not physics, so isn't dragged into discussion!

C: Well, you're certainly right when you say that many philosophers share your misgivings about relativism, and in fact I think you'll find that the few prominent philosophers who espouse something like the kinds of views you mention tend to enjoy far more popularity outside philosophy than in it. The idea that science is 'just another narrative', for example, has an air of superficial plausibility about it when not examined too closely, and it's undoubtedly a comforting thing for many people in the humanities to be told by a sophisticated philosopher like Richard Rorty; but then Rorty's pragmatism has always received a far more severe critical treatment within philosophy than in, e.g., literary criticism or cultural studies departments.

But getting back to your comment about 'infringing upon philosophical territory', one area in which your work strongly overlaps with contemporary debates in philosophy concerns something you've already touched upon, namely: emergence. You mentioned that you endorse a kind of 'emergent monism' rather than any variety of Cartesian dualism – and this perhaps relates to the impact of Spinoza's *Ethics* on the teenage Jack – but unlike many contemporary philosophers, you do not restrict your interest in emergence to specifically human or mental features such as consciousness. Rather, you argue that emergent phenomena are ubiquitous in nature: 'emergence', as you put it in *Collapse*, 'is the rule rather than the exception'.[18] The many examples of apparently emergent phenomena which you provide in both *Collapse* and *Figments* indeed make a compelling case for this thesis, but you also do not shy away from the properly philosophical task of clarifying precisely in what sense your claim that many natural systems are 'emergent' is to be understood. Given the plethora of widely divergent notions of 'emergence' one can find in the literature – and we're talking about a truly vast literature here, stretching across fields as diverse as complexity theory, artificial life, biology, physics, psychology, cognitive science, sociology, philosophy, etc. – this is of course a crucially important task. Ian has already mentioned a couple of times that which just about everyone agrees constitutes the distinguishing feature of emergent phenomena: namely, that they are 'macro' phenomena (properties, entities, systems, laws ...) which are both *causally dependent on* and yet in some sense *irreducible to* or *autonomous with regard to* their 'micro' causal bases. The real philosophical difficulties arise, of course, as soon as one attempts to clarify the precise sense in which such phenomena are said to be thus 'irreducible' or 'autonomous'; and in this regard philosophers typically distinguish between *metaphysical* or *ontological* notions of emergence, on the one hand, and *epistemological* ones on the other. To quote Paul Humphreys, whereas advocates of ontological emergence 'consider emergent phenomena to be objective features of the world, their emergent status being independent of our own existence and knowledge', advocates of epistemological emergence 'consider emergent properties to be a result of our limited abilities to predict, to calculate, to observe, and to explain'.[19] However, as with any such broad distinctions, there is of course plenty of room for manoeuvre, and one can indeed find a whole spectrum of views stretching between the 'metaphysical' and 'epistemological' poles on this issue.

---

[18] *The Collapse of Chaos*, op cit., 436.

---

[19] Paul Humphreys, 'Emergence' in Donald Borchert (ed.), *The Encyclopedia of Philosophy*, Second Edition (New York: MacMillan, 2006), x. In this article Humphreys also mentions 'conceptual emergence' as a sub-category of epistemological emergence, advocates of which 'consider emergent features to be a product of our theoretical and linguistic representations of the world' (ibid.).

So the question is, where does your own notion of emergence sit along this spectrum? From what Ian has already said, it seems that your conception is one which combines explanatory autonomy (irreducibility) with ontological and causal dependence (reducibility). Would that be a fair way to characterise it?

JC: Yes, that's more or less fair. Bear in mind that I have an easy time by saying that emergence is simply the difference between the sum of the parts and the whole, thus eliding the question of whether it's an idea or an objective natural phenomenon – perhaps the word can serve either interpretation! Emergence is, indeed, a very difficult issue. If one establishes a set of levels of understanding in the old familiar way, with God at the top and a Theory of Everything at the bottom, one can read upwards through physics, chemistry, biology, sociology and psychology, politics or whatever ... There is clearly a sense in which chemistry is dependent upon the working out of physical principles, in which biology is dependent upon chemistry (and much else …), and so on. But there is no way in which we can argue from physics to chemistry, and not only because we don't know 'all of' physics. Take any chemical item, and its explanation rests upon many physical principles; there are many explanatory roads – 'Ant Country' again.

IS: My approach to emergence views all emergent phenomena as causal consequences of underlying rules.

Emergent phenomena often *appear* to 'transcend' the underlying causality of the system, by being very different from anything we expect the rules to lead to. But this may be just our lack of imagination. It's amazing what complex things very simple rules can generate.

If the detailed deduction of the phenomenon from the rules is too long and detailed for the human mind to grasp, I consider the phenomenon to be emergent. If there is some shortcut, some structure that allows a logical deduction, I call it a theorem.

For example, from the simple 'bouncing ball' model of the gas laws, mathematicians can now prove certain technical properties ('ergodicity') which imply that, say, the system almost always distributes the pressure evenly everywhere. So this feature is *not* emergent – there is a deduction short enough to be understood. Where every atom in the room will be in ten seconds' time is emergent – but not significant. The significant emergent properties are ones that really do inform us about the capabilities and behaviour of the system. The fact that the Lorentz equations have a strange attractor is now a theorem, but it relies on a gigantic computer calculation so I'm inclined to view it as effectively being emergent. So here chaos is pretty much an emergent property according to my definition of emergence.

C: It sounds very much as though, then, for Ian at least, emergence is to be regarded as an epistemological rather than an ontological or metaphysical notion. In his recent book *What's Wrong With Microphysicalism*, Andreas Hüttemann has argued that if we take emergence to be an ontological notion, candidates for emergence that depend on the epistemological inaccessibility of explanations to human beings (as opposed to, say, a Laplacian supercalculator or what the early twentieth-century theorist of emergence C. D. Broad called a 'mathematical archangel') cannot be accepted as genuine examples of systems exhibiting emergent behaviour.[20] In this respect, if we were to adhere to an ontological concept of emergence, deterministic chaos would *not* count as a genuine example of emergent behaviour.

Yet I wonder whether things are quite so simple. Earlier on you characterised the crucial feature of emergent phenomena as being that while they are caused by the fine-scale structure and rules, they are not something that can be derived from them 'by an argument short enough for humans to follow'. Similarly, you have just said that a phenomenon ought to be regarded as emergent if the deduction of the phenomenon from the rules is 'too long and detailed for the human mind to grasp'. But I wonder if this emphasis upon the cognitive limitations of finite observers such as human beings might not be somewhat misleading, inasmuch as it would seem to suggest that all apparently emergent phenomena are merely 'in the eye of the beholder', as if the simple large-scale patterns we discern in nature are somehow illusory ('*mere* appearance'), being merely an artefact of the way in which human beings are constrained to represent the world rather than something belonging to the objective structure of reality itself. But were that the case, your conception of emergence as being 'the rule rather than the exception' for natural systems would seem to open you to the charge of anthropomorphism with regard to your conception of nature itself.

---

[20] Andrea Hüttemann, *What's Wrong with Microphysicalism?* (London: Routledge, 2004), 56; for Broad's 'mathematical archangel' see C. D. Broad, *The Mind and Its Place in Nature* (London: Routledge and Kegan Paul, 1925), 70.

However, I take it that when you say above that 'there is no mathematical scheme that can derive the large-scale structures from the small scale rules' and that 'there are no shortcuts to the patterns', you are not making a point about the *de facto* limitations upon the computational power which happens to be available to human beings, but rather about the formal limitations upon any possible mathematical derivation in principle. In other words, the underivability which you are talking about is the kind which would prove computationally intractable for even a Laplacean supercalculator, short of a step by step simulation of the entire system. But if that is the case, does this not imply that your notion of emergence is, after all, an ontological one, and that emergence as you understand it applies directly to natural systems as objective patterns in nature, regardless of whether anyone constructs a model or simulation of them or not? In other words, emergent phenomena are not simply the product of what you have aptly described as the 'quick-and-dirty feature-recognition-systems'[21] that the human brain has evolved in order to perceptually filter the underlying complexity of nature and so survive in a hostile world; rather, the latter is just one example of the way in which the emergent patterns and structures of nature itself 'collapse' the underlying sea of chaos via the complicit interaction of the phase spaces of complex rule-based systems. As you put it in *Collapse*, it is not only the human mind which sees the word in terms of simple high-level features; rather, 'the universe itself often functions by operating upon a high-level structure *as* a high-level structure'.[22]

---

[21] *The Collapse of Chaos*, op. cit., 433.

Would it be right to say, then, that your critique of microphysicalist reductionism and your attempt to develop a 'contextualist' approach to science is not a matter of bestowing some kind of ontological privilege upon those high-level, macroscopic patterns and structures of the world which happen to be perceptually available to human beings – in which case you would be open to the charge of anthropomorphism or anthropocentrism just mentioned – but rather of complementing and completing the reductionist picture of nature by developing a scientific approach which would be able to do justice to those objective high-level features of nature by treating them, as it were, 'in their own terms' or 'on their own level'?

IS: I don't think we can ever apply a mathematical concept directly to reality. If I say that some real-world feature is emergent, what I mean is that, relative to a specific mathematical model, it satisfies (or at least I think it satisfies) my definition of emergence. The real world just *does* whatever it does. The main issues are about how our attempts to understand it relate to what it does.

I would say that your summary above – your last paragraph – is a very good statement of what I think is going on. There do exist mathematical theories in which the 'higher level' structures get manipulated in their own right, as concepts on their own level. For logical rigour they must be derived from the underlying mathematical rules. An example is the idea of a strange attractor in chaotic dynamics. Mathematicians had actually proved a lot of interesting things about how attractors behave before anyone could prove they existed in a specific differential equation with any link to models of real physics. So there was a 'calculus of attractors'. Now we have effective methods to prove that some systems (such as the Lorentz equations) do have strange attractors. This completes the picture.

---

[22] Ibid., 430.

Our understanding here, however, is much better informed by the 'attractor' concept than by the vast calculations needed to prove that one exists.

JC: Treating them on their own level resonates with me. Think of a goat and some grass. The goat is emergent, in all kinds of ways, from goat embryo (*ex* goat egg, etc …). The grass has photosynthetic cells making up most of its leaves (under the silica cuticle), and it has stolons running over the ground, etc. The reductionist's goat is a physiology in lots of detail, a genome, a pelt, a grass-eater (they're really browsers, but reductionists don't care about such details); now, I'm tempted to say that the goat is emergent from the physiology, from the embryo, even from the pelt … all the ways in which the goat is a 'whole' where they are 'parts', so that the emergent properties are those that 'fill in the space' between the parts and the whole. But when the goat 'sees' the grass, it sees the high-level grass, not the cells, not the stolons. Even when it grinds it up, it doesn't relate to the cells but to the leaves – it's important that they have a silica coat, so the goats teeth get more *worn* than if it were browsing (on softer leaves-and-twigs). There's no way that the goat embryo is causally connected to this eating: It's 'goats' and 'grass', no substructure interpolated (the goat embryo just *isn't* fundamental to the goat that's eating!). The silica erodes the teeth. The goat's eyes 'see' the leaves of the grass. We see the goat; when we handle it, it's the whole goat we relate to. That's what I mean by 'at the same level'. Yes, I can take out some goat blood and get antibodies from it, investigating the way that the goat interacts with potential bacterial parasites. But there's a strong sense in which the antibodies are part of the goat: its 'defense' against bacteria (not some lower-level, 'more fundamental' structure). The cellular level seems subservient to 'goatiness' too, in a kind of top-down way – some of the emergent properties can turn around on themselves and organize the suite of emergents into goat! (There is room here for a whole argument about the recursiveness of emergents; as in, for example, Jaegwon Kim's essay, 'Making Sense of Emergence', in Bedau and Humphreys' nice book, *Emergence*.)[23]

So I don't think that this is just a matter of the way *we think about* goats and grass; I think that goats and grass interact directly, at the level of 'goats' and 'grass' – and, moreover, *that they did so before there were people!* So for dinosaurs, too, and for seaweeds and fishes – not interacting at more basic (or fundamental) levels but *as* seaweeds and fishes, with all their (emergent and other) properties intact. The fishes 'see' the seaweed. As the rock rolls down the hill, bouncing and splashing a bit here and there, I don't think it's doing very clever mathematics; I think its emergent properties (and possibly others) are interacting directly and simply – at the level of 'bounce' and the properties of mud(s), to result in the path taken. The cryptic structure of the rock doesn't affect the trajectory, just as my appendix doesn't affect the goat. That's what we mean when we say that we find emergence in the chemical and physical world as well as in the world of people.

---

[23] Mark Bedau and Paul Humphreys (eds), *Emergence: Contemporary Readings in Philosophy and Science* (Cambridge, Mass.: MIT Press, 2007).

C: You've already mentioned 'the Zarathustrans' a couple of times – a fictional race of aliens with a 'group mind' who make numerous guest appearances in both *Collapse* and *Figments* in the form of necessarily imperfect (because anthropomorphic) 'translations' of their dialogues. As you've said, this was not just a matter of self indulgence on your part: they were there not simply to add an extra populist SF edge to your work, but rather 'to jog us, and our readers, out of the safe, familiar, parochial way of thinking' and 'to push our minds in new directions, to stimulate lateral thinking'.[24] In your most recent co-authored book, *What Does a Martian Look Like?*, you mount a strongly polemical attack upon what you regard as the lamentable lack of such 'lateral thinking' in contemporary astrobiology. Indeed, you argue that the very name 'astrobiology' is an unfortunate one, betraying 'an unimaginative approach to a subject that absolutely cries out for imagination'. Instead of 'opening up new worlds, new habitats, new types of lifelike organisation', you charge that astrobiology 'narrows everything down to two existing areas of science [...]

---

[24] *The Collapse of Chaos*, op. cit., 51.

[o]ne of which has its feet firmly set on Mother Earth, while the other is mostly looking for duplicates of Mother Earth'.[25] While most current work on the science of extraterrestrials is carried out by astrophysicists relying upon out-dated folk biology, you argue for the need for 'a much wider form of thinking', a properly interdisciplinary approach to alien life which you call 'xenoscience'.[26] Could you say more about this?

IS: *What Does a Martian Look Like?* has a lot of Jack&Ian. The topic of alien life is one of Jack's long-term interests, and he has a lot of expertise, having advised major science fiction writers, and lectured hundreds of times to schools. My interest was more casual: as an SF fan, I'd often thought about the topic. We both felt that 'astrobiology' was too unimaginative – good, solid science for the most part, but much too happy to close down possibilities on spurious grounds. One symptom of this lack of imagination is the tired concept of 'habitable zone', which still tends to be trotted out on every possible occasion as if it tells us anything useful. A star's habitable zone is usually defined as the region around it in which liquid water can exist, and this is identified with the range of distances at which a planet supporting life can orbit.

Unfortunately this is such a simplistic concept that it obscures rather than illuminates. It is often stated that Venus, Earth, and Mars are within the Sun's habitable zone, and this is not too far wrong in terms of incident radiation from the Sun. But Venus is far too hot for liquid water to exist, and Mars is too cold. Why? Sure, Venus is closer than Earth, Mars further out, but that's not the whole story. An important reason is that Venus has huge amounts of carbon dioxide in its atmosphere, and Mars lost most of its atmosphere long ago, possibly when its core solidified, its magnetic field vanished, and the solar wind blew the atmosphere away – or perhaps not, it's controversial.

---

[25] *What Does a Martian Look Like?*, op. cit., 6.

[26] Ibid.

The point here is that what counts for having liquid water is not how far the planet is from the star, and how hot the star is, but how the planet's atmosphere modifies the amount of radiation that the planet receives. If Mars had Venus's atmosphere and Venus had Mars's, they'd both be a lot closer to being able to support liquid water. The Earth, in fact, is probably outside the Sun's habitable zone, strictly interpreted. That's why we have ice at the poles. It's our atmosphere that keeps us warm enough for water. Agreed, if you get *too* close to the star, or *too* far away, no amount of atmospheric tinkering can keep water liquid. But that leaves a much bigger region for water than the traditional 'habitable zone'.

But that's just the first reason why 'habitable zone' is such lamentably silly thing to bang on about. At the same time the astrobiologists were promoting the concept, NASA (and its astrobiologists) were getting excited about the possibility of life on Europa, one of Jupiter's moons. Europa is *way* outside the 'habitable zone', even interpreted more generously. But it almost certainly has liquid water. There is very strong evidence of an ocean under Europa's ice. So the imaginative question is not 'what's the most simple-minded way to rule out liquid water?', but 'what other conditions would allow liquid water to exist?' And there are lots. A planet very close to the Sun, but tidally locked, would be enormously hot on one side, very cold on the other, with a ring of moderate temperatures in between. And so on.

Up to this point, I've been accepting the view that water is essential for life. But that's not clear either. In fact there was a high-level conference on that topic at the Royal Society, and the conclusion was that waterless life is very likely to be feasible.

Now, a common response to such criticisms is to ask for evidence of the existence of tidally locked planets with a ring of water, and evidence of life that does not involve water. And of course we don't have any such evidence. But that's not as strong a rebuttal as a lot of people think, because what's under discussion here, at this stage, is the *logic* of the arguments. Is it logically correct to claim that life cannot *possibly* exist except inside the 'habitable zone'? And the answer is 'no, the logic is full of holes you could drive a truck through'. It is not necessary to find actual examples to show that the logic is faulty. As a mathematician I am constantly surprised by how poorly people appreciate this point. When exposing a logical error, it is not necessary to demonstrate which alternative argument is right. Here's a simple example. Suppose someone argues that 2+2 = 22 = 2x2 = 4. Is the logic correct? Of course not: the intermediate step 2+2 = 22 is wrong, and so is 22 = 2x2. I don't need to know what 2x2 *is* to spot these errors. As it happens the argument even gets the right answer, but that doesn't mean it is logically correct!

Astrobiologists of the 'habitable zone' variety claim to rule out water-based life except on planets that are within specific limits. That argument is wrong. It may well be true most of the time, but we don't *know* that. I think there's a bit more justification for the assumption that water-based life may be more common than other kinds – but nothing *rules out* other kinds, not yet. And basing our concept of 'life' on just one sample – one planet – is hopelessly parochial. It would be like an Inuit arguing that the only habitable part of the Earth must be the polar regions, because there's no ice anywhere else, so you can't hunt seals or make igloos to live in.

Surely the most interesting thing about alien life is that it may, just possibly, *be* alien. By all means let's put most effort into locating life like our own, because we know that definitely works and maybe the same trick has worked elsewhere. But we shouldn't rule out alternatives just because they wouldn't work here.

JC: Ian has taken quite a lot of space to sort out a major way in which our *Evolving the Alien* (a more stylish title than *What does a Martian look Like?*, for the same book) differs from standard astrobiology, and from the 'habitable zone' idea – which turns out to be mistaken. In the book we introduce each chapter with an anecdote about two (very different) aliens that are cooperating on a popular 'Visits to Earth' enterprise (from a three-bedroom house in St Albans). This was intended primarily to introduce the reader to a variety of the Earth's ecosystems, but it also exposes many Terran-centred assumptions, like the Zarathustrans in our other books. But all of the ideas that postulate aliens like Terran life forms are mistaken too; so much so that I don't know whether Terran universal/parochial ideas can work off Earth; we try to establish rules by setting out the Europa story, but we genuinely *don't know*! There are many super ideas in that book, but all of them are highly relative, not quite applicable to 'real' science. As a work of the (disciplined) imagination, it's great – and was great fun to write. But I'm not sure that you should use it as an exemplar of 'serious' science! Certainly it's scientific, in that Ian and I took the arguments very seriously (but not too solemnly), but nearly all of the arguments are relative to the possibilities that we'll find aliens some time, to test them (except, perhaps, for the bits about Ray's Tierra, computer viruses, Conway's Game of Life, and possibly sun-spots, that certainly look as if they're based in some kind of life!). It's a useful exercise for throwing out anthropic arguments, but the latter are themselves only rather silly justifications of physical constants, varied in not nearly enough dimensions. The contrast we set up in *Figments*, between the way that we introduced the Big Bang origin at the beginning of the book, and the way that a Zarathustran sees it at the end of the book (as a series of semi-realised potentialities), says a lot about anthropics: different creatures abstract different rules; which are the anthropic ones? And it also says that there isn't one way of interpreting the universe: different creatures, different interpretations; but we could so easily be simply wrong about that: many very clever people think we are – and not only Catholics!

C: Regarding so-called 'anthropic reasoning', there's no doubt that there have indeed been a plethora of very silly arguments put forward under that rubric, especially in popular pseudo-science literature. But as I understand it, your argument is not so much against anthropic reasoning per se – at least, if we understand that in its originally intended sense as merely a type of observation selection effect – but rather with the problem to which it has been typically evoked to explain: namely, that of the supposed 'fine-tuning' of the physical constants of the universe. After all, if there were ultimately a way of proving that the physical constants were indeed exquisitely 'fine-tuned', it would seem that the multiverse scenario would indeed be just about our only reasonable option, and an anthropic selection effect would then have to be invoked in order to explain why we observe the kind of universe we do. But your argument attempts to nip the whole problem in the bud from the get-go, as it were, by showing that the kind of thinking involved in the very idea that our universe is fine-tuned is not only 'misleading' and 'wrong', but even 'downright silly', being based on nothing more than 'bad logic'. One might be surprised to learn that so many eminent scientists – including the likes of Steven Weinberg, Stephen Hawking, Martin Rees, Roger Penrose, Andrei Linde, Alexander Vilenkin, Lee Smolin, Leonard Susskind, Richard Dawkins, Max Tegmark, John Gribbin, et al. – have all been guilty of such flagrant 'bad logic'. Could you explain what this charge amounts to?

JC: The business of anthropic reasoning comes under three heads, for me: Firstly, there is the 'fine-tuning' issue, which physicists resolve either by invoking a Designer who does the fine-tuning of the laws and constants, or by postulating that this one universe out of quintillions is the one which has the tuning 'just right'; it is assumed that the 'crystalline' properties of, especially, that carbon chemistry that makes physicists possible, has no flexibility whatsoever (or that it can only be moved one dimension at a time). There is no choice – it's *our* physicists or none!

Secondly, there is the 'Earth hasn't moved out of the habitable zone throughout its history' story, making control of this temperature etc. one of God's many miracles – choosing this one out of hundreds of millions of possible histories, nearly all of which failed to keep temperate! Apart from several feedback mechanisms, and that we had several Snowball earths, as well as continents of volcanoes and a few asteroid hits, can we claim that this Earth was the only one that 'made it'?

Thirdly, there is the ('Rare Earth'-type) argument from evolution: in order to get creatures that can describe what happened here, so can find it remarkable, we had to have eukaryotes/cellular life forms/echinoderms then chordates/vertebrates (or, presumably, equivalents, whatever that can mean), amphibians coming out from Devonian fishes ... Dinosaurs and the K-T meteorite had to be supplanted by mammals, and primates then apes had to do the goods. Any break or stop along the line, and we wouldn't have creatures who find the whole business so unlikely that they need to argue anthropically … Unless we agree that 'higher' life forms will arise, sooner or later, on almost any aqueous planet, so that on any planet with extelligence it must look as if the evolutionary history was both necessary and spectacularly unlikely!

Whatever happened, happened; agreed, if the sun had gone nova we wouldn't be here; and it's quite likely that only one in a quintillion planets comes to have physicists. But a hell of a lot of the others might have creatures that remark on their own unlikelihoods!

Basically, it's the old chestnut about how unlikely *you* are to have been born: that your parents met, that your grandparents met and mated, that *that very sperm* fertilized …; or that you live in a house which was not destroyed by the war … wow, you just can't exist!

Start with the idea that, however unlikely, you *do* exist! Then argue away from unlikelihoods into the common elements of existence. There must be plenty of flexibility about laws, about constants (not changing them one-dimensionally, perhaps; but if we change Planck's constant by ten percent and *then compensate* by changing the ratio of electron to proton …), about paths. There must surely be a vast phase space of possibilities, not just one particular universe whose unique solution allowed history to happen! And as soon as you allow that there are many paths, we can surely not be too surprised at existence, in almost any form! If you like, wonder at how long it took to get to physicists from fizzy clays, how long it took to get to physicists from australopithecines, why the Antikythera mechanism didn't bring the Greeks into modern physics; but then think: what happened, happened! And the alternate paths didn't (unless you think they did, in all dimensions and whenever there was a choice ... in which case, you have *more* possibilities, not less!). So the 'real' history sits among a plethora of possibilities, and is not in any sense unique. And to attempt to argue for its uniqueness by constraining the rules until it appears unique, then arguing that it had to be like that – either because God pruned all the other possibilities, or because all the other paths ran into impossibilities (such as extinction …) – is simply mad!

IS: This is a huge area so let me focus on so-called 'fine-tuning' arguments. This is about the 'fundamental constants' in the physical equations for universes – speed of light, Planck's constant, and so on. These are numbers, with no special pattern to them, and it is assumed that any choice of these numbers is in some sense just as likely as any other. The claim, widely publicised, is that our universe is virtually unique in its choice of constants: these are almost the only values that make life possible.

The argument involves the effect of changing the values a little bit. Make the gravitational constant smaller, and stars blow up, galaxies disappear. Make it larger, and everything collapses into a single gigantic black hole. If you change any one of those constants by more than a very tiny amount, it is said, then the resulting universe will be unable to support the organised complexity of life. Having lots of constants compounds this – it is like winning the lottery many times in a row. Since our universe is so improbably 'tuned for life', we then run into mystical anthropic territory: Basically, 'it must have been made specially for us'.

This claim is a wild exaggeration. One source of error is that the effect of each constant is considered in isolation, with everything else unchanged. But a change to one constant may compensate for a change to a different one – if you allow such changes. If not, you are in effect standing near Centrepoint in London, wandering a few yards along Oxford Street and Tottenham Court Road, and then claiming that there are no museums in London because you haven't found any in that limited locality.

In a recent paper in the *Journal of Cosmology and Astroparticle Physics*, Fred C. Adams[27] looked at what happens when you vary just three of the constants, those that are particularly significant for the formation of stars: the gravitational constant, the fine structure constant, and a constant that governs nuclear reaction rates. Crucially, he allowed *all three* to vary independently. He defines 'star' to mean a stable self-gravitating object that generates energy by nuclear reactions. His calculations reveal no sign of fine-tuning. Instead, stars exist for a huge range of constants: in fact, the probability of getting a universe that can make stars is about 25 percent. If you count more exotic objects as effectively being 'stars', such as black holes generating energy by quantum processes, the figure increases to around 50 percent. So, as far as stars go, our universe is not improbably finely tuned, battling odds of billions to one against. It just called 'heads', and the cosmic coin landed that way up.

This is just one flaw in the usual 'fine-tuning' claims. There are many others – including the unstated assumption that the only way to make a universe is to keep the standard equations but change the constants. In *The Collapse of Chaos* we use an analogy with cars. If you take, say, a Ford Mondeo and change the diameters of all the bolts by just a tiny amount (or indeed by a large one) then the car won't work. Either all the nuts fall off, or they don't fit on to the bolts at all. But this does not imply that the Ford Mondeo is the only possible design for a car, uniquely fine-tuned for nuts and bolts to exist. All it means is that when you change the size of the bolt, you must also change the *nuts* so that they still fit. There are tens of thousands of ways to design a working car.

---

[27] F. C. Adams, 'Stars in Other Universes: Stellar Structure with Different Fundamental Constants', *Journal of Cosmology and Astroparticle Physics*, 08, 2008: 010.

Another staple of fine-tuning, the 'triple-alpha' process in Red Giant stars that makes carbon, falls to bits because of an even simpler mistake. The claim of fine-tuning involves a remarkable coincidence of energy levels in various atomic nuclei, which allows the nuclear reaction that makes carbon to happen rapidly enough to make a lot of it. But the coincidence is not actually very remarkable, because stars have 'thermostats' which affect their temperature. Coal fires burn at exactly the right temperature to burn coal, because the nature of the chemical reaction affects the temperature. If the temperature is too low, the coal burns faster and the fire heats up. If the temperature is too high, the coal burns slower and the fire cools down. So it sits neatly in between, and the reaction works beautifully. There is nothing mysterious about this: it is merely a matter of negative feedback, which automatically stabilises the reaction and homes in on a temperature that works. It is the same with Red Giant stars.

A common metaphor in fine-tuning arguments is that our universe is 'balanced on a knife-edge'. This sounds dramatic, but it is misleading. To see why, take a steel ruler and a carving knife. First, try to balance the ruler on the edge of the knife. It will tilt, slide, and fall to the ground. This is the 'fine-tuning' metaphor made real. Now try to balance the ruler on your arm. It will obligingly tilt, wobble a little, and settle down to rest in perfect balance. The reason is feedback. Because your arm is rounded, gravity automatically pulls the ruler towards a suitable balance point. It doesn't have to 'aim for' some specific balance point – the correct angle emerges from the natural dynamics. Most natural systems are 'nonlinear' – like the arm, not the knife-edge.

C: Clearly, those who argue that the universe is 'fine-tuned for life' have things the wrong way around – as Victor Stenger has nicely put it: the universe is not fine-tuned for humanity; rather, humanity is fine-tuned for the universe.[28] However, it perhaps ought to be emphasized that the scientists I mentioned in my last question – all of whom seem to agree that the so-called 'fine-tuning coincidences' do indeed cry out for explanation – are in no way guilty of drawing such patently unwarranted teleological conclusions; nor, indeed, are the vast majority of scientists and philosophers who take fine-tuning and anthropic reasoning seriously.[29] Creationists and their ilk will of course always seize upon what is happening in science in order to furnish putative vindications of theological and teleological metaphysics – and, unfortunately, this of course sometimes includes 'believing' scientists.[30] But the fact that, for example, some such people spuriously claim that the Big Bang furnishes evidence for creation of course does nothing to invalidate modern cosmology.

[29] For sophisticated treatments of anthropic reasoning see, e.g., Nick Bostrom, *Anthropic Bias: Observation Selection Effects in Science and Philosophy* (London & New York: Routledge, 2002); G.F.R. Ellis, U. Kirchner & W.R. Stoeger, 'Multiverses and Physical Cosmology', *Monthly Notices of the Royal Astronomical Society* 347, 2004: 921-936; Milan Ćirković, 'The Thermodynamical Arrow of Time: Reinterpreting the Boltzmann-Schuetz Argument', *Foundations of Physics* 33, 2003: 467-490; Mark Walker & Milan Ćirković, 'Anthropic Reasoning, Naturalism and the Contemporary Design Argument', *International Studies in the Philosophy of Science* 20, 2006: 285-307; Milan Ćirković, 'Too Early? On the Apparent Conflict of Astrobiology and Cosmology', *Biology and Philosophy* 21, 2006: 369-379; and Milan Ćirković, 'Sailing the Archipelago', this volume.

IS: Yes, but my view is that not only is the 'fine-tuning' argument the wrong way round: basically, it's bogus. Many wildly different kinds of universe would be suitable for (wildly different) kinds of 'life', by which I mean systems as complex as living ones in our universe, with similar features (reproduction, autonomy, and so on). Stuart Kauffman employs that sort of concept of 'life' in his *Investigations*.[31] My point is that the so-called fine-tuning *doesn't* cry out for explanation. As coincidences go, they are no more rare than rolling a die and getting a 6. The 'explanation' required is not to explain why our universe is so terribly, terribly special. It is to realise that it's *not* special at all. Moreover, it's not the conclusions I'm objecting to: it's the hypotheses. The claim that, in effect, our universe is the only kind capable of supporting 'life' is simply wrong. Where that claim leads is another matter. I don't think it leads anywhere.

C: Your complaint about the practice of varying only one cosmological parameter at a time – thus assuming that they are all independent and failing to explore more than one or two axes of the whole phase space – is of course very well-taken, and is a point which others have also raised.[32] However, as Milan Ćirković argues in his contribution to the present volume,[33] this has far more has to do with the numerical intractability of *ab initio* variations of multiple parameters rather than any kind of insidious teleological or theological agenda on the part of the scientists doing the research. Moreover, the fact that such computational limitations exist is surely not a reason to give up exploring these things, but rather simply suggests that one must exercise extreme caution in assigning probabilities (if indeed it makes sense to assign probabilities to an infinite, non-normalisable parameter space at all, which also presents a very significant challenge for proponents of fine-tuning).[34] While, as you point out, several physicists and cosmologists have indeed begun to explore what happens when one varies several constants at a time,[35] and have indeed concluded that the probability of the existence of (e.g.) stellar structures may not be as low as first thought, such models are still based on the same low-entropy initial conditions of 'our' Big Bang, which have been shown, by Roger Penrose among others, to be stupendously improbable themselves (estimated by Penrose to be of the order of about one part in $10^{10^{123}}$ – a number which surely cries out for explanation).[36] Moreover, as Ćirković also argues, it is highly questionable whether such research invalidates anthropic reasoning per se, rather than simply helping to make the problems more tractable and well-defined by providing more useful data to work with.[37]

Chiba, 'The Minimum Mass of the First Stars and the Anthropic Principle', *Progress of Theoretical Physics* 97, 1997: 169-171; Anthony Aguirre, 'The Cold Big-Bang Cosmology as a Counter-example to Several Anthropic Arguments', *Physical Review* D64, 2001: 083508; R. Harnik, G. Kribs & G. Perez, 'A universe without weak interactions', *Physical Review* D74, 2006: 035006; and Milan Ćirković, op. cit.

IS: Agreed, it's difficult to do the sums correctly. So that justifies doing them *wrongly*? The universe is not obliged to behave in ways simple enough for humans to calculate. The difficulty of doing anything beyond 'perturbation' calculations, where a few parameters are changed by very small amounts, doesn't mean that the computable cases are the only ones available. It actually strengthens my point, because the claim that anything else cannot possibly support life falls to bits if you haven't got a clue how other possible universes behave. There is a huge difference between claiming that no other possibility works (which in effect is a claim of complete knowledge of the consequences of alternative laws of nature) and pointing out that since we don't know that, and cannot know that, then we cannot make that claim. What's at stake here is the logic of the argument. I'm not trying to prove that our universe is not special. I'm pointing out gaps in the logic of the claim that it is.

---

[36] Roger Penrose, *The Emperor's New Mind* (Oxford: Oxford University Press, 1999), 445.

[37] See Ćirković, 'Sailing the Archipelago', this volume.

If by 'invalidates anthropic reasoning *per se*' you mean 'shows that *any* kind of anthropic reasoning is silly' then of course nothing we've discussed does that. What I'm saying is that the 'classic' examples of anthropic reasoning are all flawed. Carbon in stars, fine-tuning – the logic is bad, the arguments are full of holes. I don't reject all anthropic reasoning. I just ask that it be done carefully and with imagination.

It's the Sherlock Holmes point – or, rather, what Holmes failed to mention. 'Once you have eliminated the impossible, then whatever remains, however improbable, must be true'. What Holmes failed to point out is that this line of thinking is hugely dangerous unless you are very, very careful that the things you claim to be impossible really *are* impossible. My view, and that of most mathematicians, I imagine, is that if what remains is wildly improbable, you probably made a mistake earlier on.

I agree with you on the problem of the application of probabilities: my use of probabilities of 25 percent rather than infinitesimal accepts the fine-tuning way of doing it (which is naïve but qualitatively defensible) to show that it doesn't lead to the claimed conclusions. 'Stars' can exist in a huge chunk of parameter space, not a tiny bit. End of story.

As for the idea of the supposed specialness of 'our' Big Bang, Jack and I argue in *Science of Discworld II: The Globe*[38] that Penrose's calculation is absurd. It assumes a purely thermodynamic universe (which is why 'entropy' comes into the story). Here all forces are short-range – acting only at the level of collisions of molecules – and repelling. The result is a long-term trend towards a uniform distribution of matter (disorder). But the real universe has many other forces, notably gravity. This is long-range and attracting – the exact opposite. The result is a long-term trend towards 'ordered', clumpy distributions of matter. If you use a thermodynamic model on a gravitic system, the results won't make much sense.

---

[38] Terry Pratchett, Ian Stewart & Jack Cohen, *The Science of Discworld II: The Globe*, op. cit., 194-5. A more extensive treatment can be found in Ian Stewart, 'The second law of gravitics and the fourth law of thermodynamics', in (ed.) N. H. Gregsen (ed.), *From Complexity to Life* (Oxford: Oxford University Press, 2003), 114-50.

I don't actually think the use of 'order' and 'disorder' when discussing entropy is very helpful, because those terms are highly ambiguous, but for the sake of simplicity let's say that a high-entropy state is disordered and a low-entropy state is ordered. Then thermodynamic effects turn order into disorder; gravitic ones do the reverse. So any natural 'final' state of a gravitic universe is highly ordered. If you now pretend it's a thermodynamic system, the initial state must have been *even more* ordered (because entropy increases over time). This leads to Penrose's minuscule estimate for the probability of the presumed initial state that would lead (by *thermodynamic* action) to the final one. However, that's not how it happens. Instead, an initially disordered state naturally clumps under gravity. 'Entropy' measured by the clumping decreases over time. It doesn't increase.

C: While the use of anthropic reasoning in astronomy and cosmology has a long history,[39] the term 'anthropic principle' itself was first introduced by Brandon Carter in the early seventies as a corrective to what he called 'exaggerated subservience to the "Copernican principle"' – that is, the inference from the idea that we are not *special* to the idea that we must therefore be *average* or even *representative*.[40] It was this kind of uncritical acceptance of what has popularly taken to be the chief lesson of the Copernican revolution which in part led many Enlightenment thinkers in the centuries following Copernicus to assume that not only the other planets, but even moons and comets, must be populated by rational beings very similar to ourselves.[41] In *What Does a Martian Look Like*, as already mentioned, you charge much of contemporary astrobiology with a similar kind of (for want of a better word) 'terracentrism', charging it with being 'by its nature too narrow-minded and too unimaginative to tackle the really big questions about aliens'.[42]

---

[39] See, e.g., J. D. Barrow and F. J. Tipler, *The Anthropic Cosmological Principle* (Oxford: Oxford University Press, 1986); Milan Ćirković, 'Ancient Origins of a

IS: That's a fair summary, and it raises a fascinating issue that I've not thought of before. Anthropic reasoning concludes that we are special; Copernican reasoning concludes that we are not special. The cosmological mainstream (or at

Longair (ed.), *Confrontation of Cosmological Theories with Observational Data* (Boston: Reidel, 1974), 291; cf. the discussion in 'Dark Matter: Probing the Arche-Fossil. Interview with Roberto Trotta' in COLLAPSE II: 83-169.

[41] On this see, for example, Frank Tipler, 'A Brief History of the Extraterrestrial Intelligence Concept', *Journal of the Royal Astronomical Society* Vol. 22, 1981: 133-145.

[42] *What Does a Martian Look Like?*, op. cit., 5.

least, many prominent members) tends to believe both of these.

Carter's point is the key. I think that it is probably correct to assume that we are not special – not in general terms. But does this imply that we are *representative*? I'd go with Carter: it does not. The reason, to use the central distinction of *What Does a Martian Look Like?,* is that we can be (and virtually by definition always are) special in *parochials* but not in *universals.*

Intelligence is a universal (we have argued, after a lot of debate, and we acknowledge that we may be wrong here – but let's take that as an example anyway). So by the Copernican view, our intelligence is nothing special. There will be lots of intelligent aliens out there.

However, our particular level of intelligence, our use of a brain as the seat of intelligence, what we do with our intelligence – many features will be parochial. Aliens won't do it the same way as us. Which implies that in these respects we *can't* be representative.

In short: to be representative *is* to be special! As soon as diverse histories can lead to the same universal result, each history will be special, and nothing can be representative. Jack and I hit this problem when writing *What Does a Martian Look Like?*: I kept asking Jack to stop saying 'we can't know what aliens look like', and he kept saying 'but it's true'. We compromised by talking of 'placeholders' – 'as long as you don't take this example literally, they might be like *this* ... but not in any of the details'.

C: Perhaps you could explain what you mean by 'universals' and 'parochials'. This distinction was introduced in *Collapse*,[43] developed in *Figments*,[44] and you put it to work in *What Does a Martian Look Like?* in order to hazard educated guesses regarding which kinds of biological features we might hypothetically expect to find exhibited by extraterrestrial life forms. Could you explain how one sets about trying to distinguish between the 'universal' and the 'parochial' in evolution, and what tentative conclusions you have reached regarding the possibilities of alien life?

JC: It is essentially a very simple idea, and argues the 'likelihoods' of events – innovations – in *our* evolutionary story. If an innovation happened just once, this tells us that it is possible, but not how likely it is to have happened – perhaps the invention of DNA was such an event. On the other hand, eyes evolved in many different clades, apparently independently (although there are some puzzling equivalencies in some of the biochemistries), making it appear likely that eyes will evolve. If we 'ran Earth again', or found another planet on which eukaryotes (or equivalents …) had evolved from prokaryote (bacterial/archaean) progenitors, we would expect to find eyes. But DNA? We would not be able to argue for DNA *in the same way* (but there might be chemical reasons to expect it – or not!). Similarly for photosynthesis: there are five extant methods of photosynthesis. Granted an oxygenated atmosphere, then flight would be expected: insects, birds, bats, pterosaurs, and some fishes all invented flight independently; we would expect flying life forms on a re-run Earth, or on another aqueous planet. I have suggested that we call such multiply-invented innovations 'universals', while those innovations – nearly all of them – that happened but once in our evolutionary story I call 'parochial'. Vertebrates are parochial – we won't find that pattern elsewhere (nor would it occur again on a re-run Earth). So are feathers; and hair (but not 'fur' – bumble bees have it for warmth, as do many plants – mammalian hair is a parochial instance of the universal 'fur').

---

[43] *The Collapse of Chaos*, op. cit., 404.

[44] *Figments of Reality*, op. cit., 109-134.

Now there is the question of whether our universal/parochials are transferable to other planets, and the answer is: We simply don't know. We don't know how different even the most earth-like aqueous planet will be. But we can certainly rely on the negative: We won't get vertebrates! But whether we'll get flight or photosynthesis … ?

IS: We started out with Jack's working definition: a feature is universal if it has evolved independently more than once, and parochial if not. That works fairly well for life on Earth, but if aliens exist that may be too small a sample. So I argued for a more 'mathematical' definition (or characterisation): if some feature or mode of behaviour offers evolutionary advantages for generic reasons, it's a universal. By 'generic' here I meant that the *reasons* should be valid in many diverse contexts. So having a sense of vision ought to be universal, because it helps you detect danger in almost any form.

On Earth, vision evolved many times, so in this case the two approaches to universality coincide. In a way, my definition is a theoretical one and Jack's is the experimental test. But when it comes to aliens, we can't yet do the experiments.

C: According to your book, many proponents of orthodox astrobiology – most of whom are astrophysicists rather than biologists – 'seem not to have realised that there has been a revolution in evolutionary thinking during the 1980s, just as radical as the Newton/Einstein paradigm shift in physics', one consequence of which being that they 'are ruling out various scenarios for alien life, even though those scenarios already occur on this planet'.[45] 'Our own planet', you suggest, 'is far weirder than anything permitted elsewhere by astrobiological orthodoxy'.[46] For those still not 'in the know' on all this, could you describe what this recent revolution in evolutionary thinking amounts to, and provide some examples of the (from the human point of view) weird and wonderful forms of life only recently discovered on our planet?

JC: The evolutionary paradigm is usually taken, by philosophers and physicists – but also by many biologists – to be that of the 1950s: all the organisms of a population have much the same genome (hey, that's why they belong to the same species …), but a few have mutations that usually make things worse but occasionally make things better (because if you fire bullets randomly at a car engine you'll mostly damage it, rarely improve it!). So most mutations are lost in the first generation ... or so they thought!

---

[45] *What Does a Martian Look Like?*, op. cit., 7.

[46] Ibid., 39.

Lewontin's group in the 1970s[47] (and hundreds of others since) discovered that wild animals and plants – and humans – are not like that at all: in a typical individual about 10 percent of the genes are heterozygous (different versions from Pa and Ma) and about a third of genes have different version(s) in the population (say, more than 1/1000 individuals – with rarer mutations, it comes up to about two-thirds or more!). So lots of old mutations are still about, recombining in different assortments in each of the progeny. That's much more like Darwin's picture, incidentally, which he got to by arguing from domestic species (mostly pigeons!). Each of the progeny is different in many genetic respects, and only because of 'genetic assimilation' and other developmental tricks can so many actually develop, the developmental programme is so diverse. Put this against the Malthusian background – so many progeny, so little room. Realise that 1/1000 survival is not unusual, 1/million or even 1/100 million is found in oysters and codfish; 1/8 in songbirds like starling (a female starling lays about sixteen eggs in her life, which 'on average' produce two parents in the next generation – only 'averages' ain't the way to calculate), 1/4 in hippos and rhinos, 1/3 in elephants. Most progeny fail to breed. And because they are all so genetically different from each other, this is mostly because of different programmes; but *because they are all so different* what is being selected is not particular genes, but particular – and very varied – combinations for the next generation. By any number of developmental tricks, these different versions can all develop, but they are not like Ford Model

---

[47] R. C. Lewontin, *The Genetic Basis of Evolutionary Change* (New York: Columbia University Press, 1974).

T's, some with bumps and a few with better headlamps etc; they are like handmade cars, all adjusted differently to give much the same results. Add to the puzzle that the parts that they are using are very various, perhaps from the last ten models (and a few from similar models …), and it is clear that the DNA genome ain't even half of the trick – the RNAi (which were thought to be products of 'junk' DNA) turn lots of genes on and off in different tissues, and there are perhaps thirty other tricks we know about (epigenetic tricks, for example, that carry information to the next generation by modifying DNA …) – as well as the hundreds we don't know about yet.

So the picture we should have of alien genetics is not at all the Lego model: has it got the right genes? So diverse is the developmental/genetic system *here* that we have to suppose that at least equivalent complexity would be needed to 'drive' an alien ecology, even just a bacterial-grade one. To get 'higher' organisms we must invent a whole new slew of *really* complicated/complex biology, that involves selection of *genetic variety of progeny*, not just selection of progeny!

We have, now, hundreds of 'anomalous' species on earth, that don't fit the new paradigm of genetics, let alone the 1950s one. From parthenogones (females only ...) in some rotifers, for 100 million years, to a whole slew of genes that have been 'shared' by 'primitive' (bacterial and archaean) genetics, to a variety of genes that have been lifted across from species to very different species by viruses, to cichlid fishes of Lake Victoria with morphologies that are very various, from nearly a metre long to 2cm (a female that is kept in a snail shell by a male, and fed there), we now know of life forms with an enormous variety of life strategies – but with a genetic variety that is only about that of human beings!

C: In both *Collapse* and *Figments* you draw upon the massive evidence for evolutionary convergence to take issue with Stephen Jay Gould's argument that, if one were to re-run evolution on Earth, nothing like human intelligence would evolve a second time around. Intelligence, you argue, is a universal. What, then, do you mean by 'intelligence' here, and what is the evidence of convergence that led you to the conclusion that it is a universal – that is, something one might expect to find on any planet with a comparable biological complexity to that of the Earth? Presumably, unlike Simon Conway Morris in his recent *Life's Solution: Inevitable Humans in a Lonely Universe*[48] – apart from strongly disagreeing with his 'lonely universe' conclusion – you do not suppose that this 'universality' or 'inevitability' of intelligence has any special 'metaphysical' (read: theological) implications!

IS: It's worth noting that Gould himself rather backtracked on his claim. It was a way of dramatising the remarkable diversity of life in the Burgess Shale. (Which may also have been exaggerated, according to more recent studies of the fossils.) We would agree with Gould that *humans* would not evolve the second time round. Not just like us. Too many accidents of history are embedded in our genes. However, that doesn't rule out similarly intelligent creatures evolving by a different route, and we rather think they could – and, given long enough, should.

---

[48] See note 30 above.

What do we mean by 'intelligent' here? I don't want to try for a philosophically waterproof definition (too hard). Informally, intelligence (as we experience it) has a number of striking features. The ability to manipulate mental models of the world, to ask 'what if?' questions, to let future prospects affect the present, and so on. As a universal, 'intelligence' ought to have similar features. You can construct your own list.

If we are right that intelligence is universal then it should evolve many times, either in a single run of this planet or in hypothetical multiple reruns. In effect, Jack's experimental test should work. So we would expect some kind of intelligent creature to turn up, some time. If intelligence is a parochial, limited to us and *our* evolutionary history, then Gould would be right, and intelligence would have lost its chance to evolve on Planet Earth.

JC: The answer to the question of whether intelligence is a parochial or a universal, in our evolutionary scheme, comes out as a resounding 'universal': from mantis shrimps to octopuses, geckoes to owls, dolphins to killer whales, creatures that 'think' have evolved many times - here. But can the same be argued for other planets? I like to think that it can; like Ian, I put it into a theoretical context: like vision, intelligence is a general way of dealing with the world, and will be 'chosen' frequently. So my prejudice is that we'll have (equivalents of …) mantis shrimps and killer whales, owls and octopuses on all those planets that have taken the steps towards the multicellular (or bzqwar … I don't know that multicellular is the *only* way 'upwards'!) – intelligence, in a variety of forms, will be rife, as it is here.

But extelligence? That is a quite different matter. There are steps towards extelligence: chimps, meerkats, wild dogs … so it could be claimed as a universal; but then these are all mammals, so should we count this as one single case (Mammalia), thus making it a parochial? Really, however, there is only one case: us. Only we have more information outside the brain (in other brains, initially …) than inside the individual brain – so that a Make-a-Human-Being kit requires pouring a whole lot of cultural stuff into each of us, as we grow up. How likely is that on another planet? Well, taking Ian's stance on universals, pretty damn likely, given time! It's clearly the best way (so far ...) of exploiting intelligence, transforming it into cultural capital that grows down the generations – becoming 'extelligence'.

Simon Conway Morris has an interesting take on this issue. Because he is Christian, he sees the 'highest' form of life on any planet (that's got far enough …) as being effectively, and morphologically, humanoid; essentially, he believes that the form of life 'made in the Image of God' is effectively the top of *any* evolutionary tree. Like Waddington, he believes that our morphology is just about 'right', and uses the (alien) convergences in evolutionary pattern to get there. Well, it may be so. If there actually *is* a real theology, that is to say there actually is a Someone who organized the whole matter, then one would perhaps expect to find that kind of contingency – if the Someone were smaller-minded than I would hope!

C: In *Figments* you introduced the ideas of 'privilege' and 'extelligence' by way of providing an evolutionary account of the origins of the peculiar nature of human intelligence and culture. These are remarkable ideas which one feels really ought to have achieved wider currency than they have so far. Could you briefly explain what you mean by these terms?

IS: I'll let Jack do 'privilege', because it was his idea long ago. 'Extelligence' came from a discussion between us both, but it was my word, so I'll tackle that.

The reason that humans have overrun the planet (and consider themselves Top Dog, or rather Top Species – although there are other contenders, depending on criteria) is *not* that we are intelligent. It helps, but it doesn't go far enough. Purely intelligent mortal creatures have to reinvent the wheel (literally) in each generation. Lessons derived by the exercise of intelligence have to be relearned – they can't be passed on.

But if some sort of cultural memory exists, the next generation can build on the lessons learned by the previous one. The mechanism can be as simple as mother dog teaching the pups where to find water, or as sophisticated as the Internet. But without it, 'civilisation' could never have happened, and as individuals we would be virtually powerless. We'd be back in the caves, battling the monsters, staving off starvation on a day-to-day basis.

Anything that can pass 'cultural capital' or 'know-how' down the generations we call 'extelligence'. It is that part of our intelligence *as a species* that does not reside in all (most) individuals. Until a few thousand years ago each bit of it resided in the brains of specific individuals – the copper-beaters knew all about making things from copper, and so on. It was passed on by word of mouth, often from parent to child.

Our ability to manipulate the planet to our own ends started to take off when we found ways to store this stuff *outside* human brains. We carved it on walls, wrote it in papyrus, whatever. Now the amount of 'extelligence' is limited only by the available space to store it, not by the capacity of one human brain. Its use is limited by our ability to access it, as well.

JC: In my 1977 book *Reproduction*[49] I invented the idea of 'privilege', as that which offspring receive from their parents, to give them a start in life. So yolk, milk, starch, etc., represent food that could have been used by the parent chicken, cow, wheat plant, etc., for its own purposes, but that has been donated to the offspring to help give them a start, to give them privilege. Laying eggs in the right place (e.g., on a paralysed spider, or on a mammalian corpse), counts as privilege – so does sending the child to a special school. So this is a very general concept, emphasizing that the break between generations is not very 'clean'. Equally, of course, teaching/learning is another instance of this passage across the generations, initially in the nest: cats teach their kittens to deal with prey. (This seems to be a solely mammalian trait – other nests, like those of some turtles, crocodilians or even cephalopods seem to have no passage of information – even birds don't seem to 'teach' their young.) From those small beginnings, however, arose languages like those of wild dogs (whose puppies learn the pack's special noises for 'hunt'), leopards, eagles; surprisingly, perhaps, chimps – our closest relatives – don't have much by way of language-learning, perhaps less than dogs; a few monkeys, especially vervets, have tens of 'words'.

---

[49] Jack Cohen, *Reproduction* (London: Butterworth, 1977).

Our trick has been to explode this initial trick into complex language, by which we pass a tremendous amount of information from maternal brain to infant brain, accumulating cultural capital across the generations. Priests, as temporary repositories of the cultural capital, made it much more stable, ubiquitous. Then writing, to produce a more permanent store … teachers, specialists in passage, then books, libraries, the Internet. Knowledge outside brains, for which Ian invented the happy word 'extelligence'.

C: In *What Does a Martian Look Like* you suggest that the question of whether extelligence is a universal or a parochial is 'the central question of xenoscience'.[50] What conclusions did you reach?

IS: Well, in brief, if it's *not* a universal it surely *ought* to be one! But it's not yet possible to make too strong a claim. With intelligence, we can argue that there is experimental confirmation of universality: it evolved many times – octopus, dolphin, monkey ... But right now we are the only extelligent species on the planet.

Finding aliens (even bacteria) would be fantastic. Complex aliens, at the level of a snail, would be amazing. The level of intelligence of a cat – awe-inspiring. But what we really mean by 'alien intelligence' is actually *alien extelligence*. That's the big one. It's the extelligent aliens who would be able to build those massive starships and travel across the Galaxy. The merely intelligent ones would reach dolphin level, and stay in their oceans or methane-pools or crystal forests or whatever, stuck on their home world.

---

[50] *What Does a Martian Look Like?*, op. cit., 277.

JC: I think there are too many unknowns. We don't know if we can transfer the ideas of universal/parochial to any other planet – though of course I'd like to think that we could! Then there's the whole question of whether extelligence derives naturally from intelligence (does it need a nest, for example? I played with this question in Harrison's *West of Eden* series, inventing an r-strategist extelligence [r-strategists have many offspring, not looked after …]; and we produced another in *Wheelers*). Too many intelligent creatures on this planet *haven't* developed extelligence (even k-strategists, who look after their few babies)! So I'm not optimistic. But there are hundreds of millions of planets out there. Who knows?

C: When first introducing the topic of 'alien science' in *Collapse*, you did so in the context of raising the question of whether the so-called 'laws of nature' discovered by science are genuinely objective features of reality itself, or only 'brain puns' which happen to appeal to the pattern-seeking human mind, by considering the question of the extent to which we might expect alien sciences to be congruent to our own. An idea which has often been forwarded in this connection is that while it is doubtless the case that much of our science is indeed distinctively 'human' or 'anthropomorphic', reflecting the peculiar nature of our species' physiological make-up and idiosyncratic modes of perceiving and conceiving the world, when it comes to *mathematics* or *mathematical natural science*, at least, we can be far more confident that we are indeed tracking genuinely objective patterns of nature itself – patterns which, therefore, we might expect also to have been discovered by any sufficiently advanced science. A century ago, for example, Max Planck characterised the history of the physical sciences in terms of a progressive unification brought about the liberation of the physical world-picture from 'anthropomorphous elements', ultimately resulting in the discovery of 'universal constants' which, he maintained, 'must necessarily retain their meaning for all times and for all environments, terrestrial and human or otherwise'. It is only if such constants retained the same significance for 'the inhabitants of Mars, and indeed all intelligent beings in our universe', he suggested, that it would be meaningful to say that, for example, 'the principle of the conservation energy was valid in nature, before any man was able to think about it, or that heavenly bodies will still move according to the laws of gravity when our earth, with all its inhabitants, has disintegrated'.[51]

This issue of how peculiarly 'human' our own science may be in relation to the phase space of possible sciences in general is a recurring theme of all your co-authored works. What, then, are some of your own conclusions on this issue? Are there any aspects of modern science and mathematics that one might reasonably expect to find represented in any possible science, even that of extraterrestrials with very different modes of perceptual access to the world to our own; or is human science, necessarily and inescapably, only ever going to be *our* science, irremediably marked by the peculiar environment, evolutionary development and modes of access to reality of the human organism and its instrumental extensions? Is mathematics, at least, able to gain traction upon what used to be called the 'primary qualities' of nature, and thus provide knowledge of a reality entirely uncorrelated with peculiarly human modes of access to it; or is mathematics, too, only 'our' mathematics?

---

[51] 'Max Planck, 'Die Einheit des physikalischen Weltbildes', *Physikalische Zeitschrift* 10, 1909: 62–75; translated as 'The Unity of the Physical World-Picture' in Stephen Toulmin (ed.), *Physical Reality: Philosophical Essays on Twentieth-Century Physics* (London: Harper and Row, 1970), 1-27; also translated as 'The Unity of the Physical Universe' in Max Planck, *A Survey of Physical Theory* (New York: Dover, 1993), 1-26.

IS: We could let our imaginations run riot and invent aliens with virtually any kind of theory of the workings of the universe, including none at all, but I don't think such speculations would be very useful. On the one hand, it's not a good idea to assume that an alien view of the universe *must* be similar to ours. On the other hand, mathematics and science developed from questions about the world around us, so we might expect aliens to have come to similar conclusions.

There are merits to both arguments, I think. You may have noticed the phrases I used – 'On the one hand/On the other hand' and 'view of'. These metaphors involve human physiology, and you can make a case that (say) our two-valued true/false logic may have been influenced by various dualities in our daily lives. Working from inside the human mind, as we all do, it may be difficult to determine how strongly (muscle-power ...) our world-view (here we go again ...) is influenced by this limitation.

But equally, the number system (1, 2, 3 ...) or the conservation of energy do seem rather basic, and we might reasonably expect aliens to have related concepts. I wouldn't want to place too much weight on that, though. I do think that if aliens have developed similar ways of thinking to us, so that they have some sort of 'alien maths', say, then it should be consistent with ours. A universe in which Fermat's Last Theorem is true on planet Earth but false on Zarathustra is a bit too wild for my taste.

However, it's not at all clear to me that what we think of as basic maths would necessarily be what an alien would think of as basic maths. I'm not worried about, say, base-10 versus base-12 numerals, or whatever: those are parochials, not universals. But would aliens have a concept of whole numbers – counting – at all? Imagine wispy creatures that float in the turbulent atmosphere of a gas giant like Jupiter, always growing whole, being ripped apart by the winds (this is how they breed ...). They might not have counting numbers because there's very little in their world to *count*. Few discrete structures exist: all is flux. 'One, two ... no, it's gone ...'. But their intuition for turbulent fluid flow (which for us is an almost intractable mathematical problem) would be amazingly advanced compared to ours. Some theoretician might introduce 1, 2, 3, ... as a topological invariant for systems of vortices. For these aliens, $2 + 2 = 4$ would be a major theorem. Even more speculatively, a creature made of gravitons (hypothetical particles that carry the force of gravity) would develop a very different physics from us.

If the two races came into peaceful contact, the synthesis of their 'mathematicses' and 'physicses' would be very powerful, and I'd expect some really extensive complicity to transform everything completely. But it would take a lot of effort, because it would all be cross-paradigm to start with.

Many scientists would simply assert that science is science and being human has nothing to do with it. I think this is too simplistic. The other extreme, the notion that science can be anything we all agree on, is worse – it exaggerates the human element, ignores the way scientists try to disprove their own theories, and is ultimately self-destructive. However, science isn't just about the answers you get, but about the questions you ask. Even today, different cultures often ask different questions and use science for different purposes. Aliens might ask *very* different questions. So while one part of me would be delighted if my chosen subject, mathematics, were the basis of reality, the more cynical part doubts that this could be the case.

Gregory Benford, a top-notch science fiction writer and an excellent physicist, once wrote an essay (in *Analog* magazine somewhere, I think) based on the distinction between two very different ways of looking at the world:

(1) Humanity is the context for the Universe;

(2) The Universe is the context for Humanity.

That is: do you (1) think of humans as what's important, and everything else as some kind of support or resource system for us to exploit? Or do you (2) see humans as one small, local consequence of whatever is going on out there is a gigantic universe, about which we know very little?

I've come to realise that almost all of the world-views with which I have serious disagreements adopt (1), and that almost all of my contrary stances are based on (2).

JC: I believe, as you say, that human science is 'necessarily and inescapably, only ever going to be *our* science, irremediably marked by the peculiar environment, evolutionary development and modes of access to reality of the human organism and its instrumental extensions' – yup, afraid so! Think, if we – Rutherford, I suppose – had started with the proton rather than the electron, we'd have a whole different zoo of particles, and different equations and constants, which would explain the natural world just as well. Or do you think that we would have converged on to electrons, and Planck's constant, because they are actually *there*? I have no such confidence; we had a good, workable system, electrons, protons, mesons; as soon as we went down into quarks I was completely persuaded that there are a million such systems, and that we had found another workable one – or invented one, it doesn't make much difference.

C: Finally, looking back on your many years of collaboration together, what would you each single out as the most important contributions which 'the collective entity Jack&Ian' has made to contemporary debates? Which of the ideas of Jack&Ian do you expect might stand the test of time?

JC: I'd like to think that the deep meaning of complicity will open up thinking in that area – people are still thinking that A affects B, then B affects A … when it is at least A' and B' by then … Extelligence is a wild card – it crept up on us from my idea of cultural capital, accumulating across the generations … The idea that simplicity is the problem, not complexity ... And mostly, the meta-idea that one can be serious – deadly serious – without being solemn!

IS: I have a real difficulty here because I have no idea how much influence any of those books has really had. So I hesitate to claim any credit.

For instance, it is very noticeable that conventional astrobiologists are finally beginning to appreciate just how different alien life might be. Focus is shifting, to some extent, from Earth-like worlds to more diverse settings. But I don't think that has happened because we wrote *What Does a Martian Look Like?* I think we just rode the wave a little bit ahead of the scientists who were doing serious research in that area instead of just writing a pop science book about it.

'Extelligence' is a nice concept. Right or wrong, I think it encapsulates an important point of view. I would also like to think that 'complicity' in our sense will turn out to be useful.

Most of all, I'd be delighted if more people took the attitude of the Zarathustrans' 'Institute for Simple Systems' – in which demolishing a wing of the library, because it has been superseded by greater *understanding*, is an event to be celebrated.

1. INTRODUCTION: MULTIVERSE AND ARCHIPELAGO

We live on a small island. We have not yet ventured much beyond our immediate locale on this small island; even our own inconspicuous location still holds great mysteries for us. It seems that we find ourselves near the mountain peak on our island, but even that is uncertain. We have only recently discovered that there are other islands besides our home scattered in a vast (possibly infinite) ocean. And the ocean is dead. It is not just devoid of fishes, algae or anything similar – it is empty of any *conceivable* form of life; it epitomizes the absence of life itself. But recently we have made our first attempt at mapping our surroundings and, in particular, sketching the outline of the ocean shores.

---

[1] It is a pleasure to thank Damian Veal for kind encouragement and very helpful comments on the subject matter of this essay. This work has been partially supported by the Ministry of Science and Technological Development of the Republic of Serbia through project ON146012. Useful discussions with Irena Diklić, Richard B. Cathcart, Anders Sandberg, Nick Bostrom, Petar Grujić, Tanja Berić, Robert J. Bradbury, Slobodan Popović, Max Tegmark, Branislav Šimpraga, Ivana Dragićević, Clément Vidal and Robin Hanson are also hereby acknowledged. This is also an opportunity to thank the *KoBSON* Consortium of Serbian libraries, which enabled at least partial overcoming of the gap in obtaining the scientific literature during the tragic 1990s. Aside from the sources cited, some of the biggest inspiration for this study came from various writings of Thomas Pynchon, Stephen Jay Gould, Howard P. Lovecraft, and Charles Stross, as well as the music of Nat King Cole, Nick Cave and the Bad Seeds, and Diana Krall.

In this, some of us bear similarities to the great adventurers of the European Age of Exploration in the fifteenth and sixteenth centuries; only in this case the explorers are not sea-captains and conquistadors, but theoretical physicists, cosmologists and philosophers.

Before I explain the central metaphor of the *Archipelago of Habitability*, I wish to emphasize how difficult and different from our modern experiences cartography once was.[2] Imagine the huge tasks facing the explorers of old – for instance, that of mapping a newly discovered South Seas archipelago with the rather crude geographical and navigational means at their disposal. No *Google Earth* or aerial reconnaissance surveys or photography. On the contrary, the explorers of old had to rely on quite uncertain and imprecise navigational aids – including often very vague time-keeping. It is hardly a wonder that their maps were usually very wrong in their details, and at best imprecise and fanciful. This is a point to keep in mind when we discuss this much vaster and more abstract Archipelago.

Five developments in the physical sciences which have taken place in the last ten to twenty years mark the intellectual convergence necessary for discussing the Archipelago:

(1) The emergence of the 'new standard' cosmological model of the flat universe dominated by dark energy (after 1998),[3] connected with the predominance of the inflationary paradigm; especially chaotic inflation seen today as

---

[2] Splendid recent histories of the subject can be found in J.N. Wilford, *The Mapmakers* (New York: Vintage, 2001) and R. E. Ehrenberg, *Mapping the World: An Illustrated History of Cartography* (Des Moines: National Geographic, 2005).

[3] E.g., S. Perlmutter et al., 'Measurements of Omega and Lambda from 42 High-Redshift Supernovae', *Astrophysical Journal* 517, 1999: 565-586.

the generic form of the process.[4]

(2) The astrobiological 'revolution' (1995-today), offering a new unified framework for the old set of questions about the place of life and intelligence in the cosmic context.[5]

(3) The rise of string theory as the best candidate for the 'Theory of Everything' and the realization that it implies a huge number of low-energy sectors (or vacua) forming a 'landscape'.[6]

All these developments have contributed something to the tremendous increase in work on various theories of the *multiverse* – a term promoted (if not truly invented) in popular culture by the great British novelist Michael Moorcock.[10] In general (though the particulars may vary), a multiverse is a set of large, causally connected cosmological domains – conventional universes. The multiplication – no pun intended – of multiverses has occurred over a wide spectrum of disciplines, from cosmology and mathematics to quantum information theory to philosophy: see Tegmark's review[11] and the popular books of Rees or Vilenkin[12] on the subject. In the rest of this paper, we shall use the anthropic landscape of string theory as the prototype physical realisation of the multiverse, while strongly emphasising that it serves just a placeholder and that no conclusion is crucially dependent on this choice.

The idea of the Archipelago of Habitability was introduced by Max Tegmark in his intriguing paper on the relationship between mathematical and physical worlds.[13]

Conceptually:

The Archipelago of Habitability: A set of regions in parameter space describing those parts of the multiverse which are hospitable to life and intelligent observers of any kind.

In the language of physics, the Archipelago is a subset of the anthropic landscape of either string theory or any other overarching 'Theory of Everything' with multiple low-energy solutions ('vacua'). Thus, the Archipelago is part of the abstract space defined by whatever physics determines the structure of the multiverse. It is both logically and physically contingent on the reality of the multiverse; but that is still not saying much, since, as Tegmark emphasizes,[14] simple variants of the multiverse are completely uncontroversial and legitimate consequences of our firmly established cosmological theories. Whether the multiverse is infinite – as in the currently popular cosmological theory of eternal inflation – or finite – as in some construals of the string theory landscape, reflects directly on the structure of the Archipelago as well.

What is an island?[15] It is a set of parameters describing habitable universes which are close in parameter space; whether we can specify the meaning of 'closeness' beyond simple intuition depends crucially on the structure of the multiverse itself. In other words, the multiverse imposes a natural or at least convenient metric upon the Archipelago. By definition, there is at least one island in the Archipelago – our home island. If the multiverse contains arbitrarily small variations in the constants of nature or cosmological parameters or even the mathematical shape of physical laws, than it is reasonable to conclude that the Archipelago is as dense as the remainder of the multiverse; for instance, it is clear that the change in the coupling constants of fundamental forces of 1 part in 10^{50} in comparison to those actually existing in our universe (not those actually measured, since we are unable to measure them to such precision yet!) – will not change anything in the habitable status of our universe. If such minuscule variations are actually realized within the multiverse, a universe otherwise described by identical laws and parameters to ours also belongs to our habitable region = our home island. It is easy to see that various constants and parameters of the multiverse play the role of geographical coordinates in maps of terrestrial archipelagos. Thus, if we start on a land point in, say, Sumatra, and continuously (or in sufficiently small steps) change either longitude or latitude along any chosen direction, we are bound to end up in the ocean. Similarly, if we start with a universe like ours and continuously change some parameter – say the strengths of forces, or the baryon-to-photon ratio, or the cosmological constant – we shall inevitably end up in a universe lacking prerequisites for life and observers. However, in the same manner as it is possible to start in Sumatra and, by a non-continuous increase in longitude, to end up in some other island – for example Borneo or New Guinea – it is possible that after a large interval of non-habitability, our parameter again enters an interval which (with appropriate changes in other parameters) enables the existence of life and observers. Thus, even if we did not know anything about possible different habitable universes

---

[14] M. Tegmark, 'Parallel Universes', op. cit.

[15] Cf. M. Houellebecq, *The Possibility of an Island,* trans. G. Bowd (New York: Vintage, 2007).

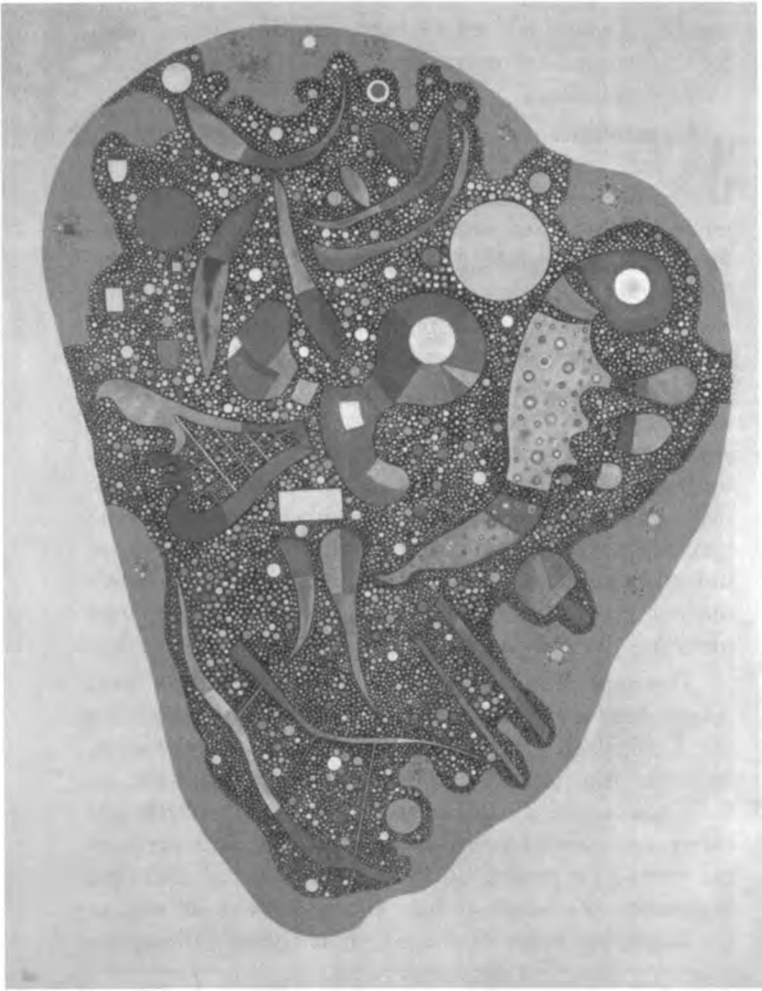

Figure 2. *Colourful Ensemble*, Wassily Kandinsky's 1938 canvas (Musée National d'Art Moderne, Centre Georges Pompidou, Paris), can be regarded as a symbolic representation of the multiverse: no colour is special as long as it is embedded in a wider ensemble.

(see §3), it would still be both rational and prudent to allow for the existence of other islands beyond our home island in the Archipelago.

Copernicanism is inscribed in the Archipelago picture right from the start – we are dealing with the widest conceivable ensemble in which our universe can be embedded, so as to avoid assigning it any special status. From the very beginning of the Copernican revolution, we have witnessed the loss of special status for ever-wider and more encompassing environments. First we concluded that there is nothing special about Earth, then about the Sun or the Solar System. In the 1920s, we finally realized that even our Galaxy, the Milky Way, is just one of billions of galaxies spanning the distance to our cosmological horizon. Now, in the twenty-first century, we should not be surprised to learn that, in spite of the apparent fine-tuning, there is nothing special about the whole of our cosmological domain – our universe – either.[16] Only in that manner will our universe's obvious property of being home to life and intelligent observers be adequately and naturalistically appreciated.

The exposition in the rest of this paper is as follows: After a brief survey of the role of astrobiology in defining the Archipelago (§2), I analyse recent discoveries of other habitable islands in some detail, with an emphasis on their philosophical significance rather than on technical issues and computational procedures (§3). This prepares the ground for putting the recent resurgence of anthropic arguments in cosmology into a new context, as well as for answering some of the common and/or fashionable

criticisms of anthropic reasoning (§4). Most of the latter are based upon the alleged teleology of anthropic reasoning, a widespread and quite robust meme which has infected large segments of both philosophical and scientific populations, but which is nevertheless misleading and wrong. Finally, some summarized points and prospects for further research are given in the concluding section (§5).

2. ASTROBIOLOGY AS MAPMAKING

We are lucky enough to live in an epoch of great progress in the nascent discipline of astrobiology, a discipline which deals with three canonical questions: How does life begin and develop? Does life exist elsewhere in the universe? And what is the future of life on Earth and in space? A host of important discoveries has been made during the last decade or so, the most important certainly being the discovery of a large number of extrasolar planets whose number increases on almost weekly basis; the existence of many 'extremophile' organisms possibly comprising Thomas Gold's 'deep hot biosphere';[17] the discovery of subsurface water on Mars and the huge ocean on Europa, and possibly also Ganymede and Callisto; the unequivocal discovery of amino-acids and other complex organic compounds in meteorites; the modelling of organic chemistry in the atmosphere of Saturn's moon Titan; the quantitative treatment of the Galactic habitable zone; the development of a new generation of panspermia theories, spurred by experimental verification that even terrestrial microorganisms can easily survive conditions of an asteroidal or a cometary impact; methodological progress in the Search for ExtraTerrestrial Intelligence (SETI) studies, etc. However, the epistemological and methodological basis of astrobiology and SETI presents us with a hornet's nest of issues which, with a few exceptions, have not been tackled in the literature so far.

---

[17] See T. Gold and F. Dyson, *The Deep Hot Biosphere: The Myth of Fossil Fuels* (New York: Springer, 2001).

One such issue is the role of astrobiology in mapping the Archipelago of Habitability, which, it is worth repeating, is a continuous part of the general parameter landscape – with the sea level defined on the basis of our understanding of habitability. Even more, habitability determines the altitude profile of an island in the Archipelago: how high will it be, will it have steep or shallow slopes, great plains or even depressions inside it, and so on. We all agree that our universe is hospitable to at least some forms of life and there is very strong empirical evidence that significant changes in values of some or all parameters will lead to an inhospitable universe (the subject matter of classical anthropic 'fine-tuning' arguments, to be considered in the next section). Asking about the sea shores of the Archipelago is tantamount to asking Schrödinger's famous question 'What is life?'.[18]

There are many ways of surveying the Archipelago, just as in terrestrial geography one can either do satellite imaging, or search for water, or observe in the infrared, or do mineral prospecting, and so on. It is impossible here to give more than a cartoonishly brief sketch of some of the directions currently being actively pursued (although not always, or even mainly, recognized as belonging to the astrobiological domain; but such is often the historical pathway of young interdisciplinary fields). Research dealing with the preconditions for life and observership as we know them in a physical, chemical or geological sense is a part of the mapping endeavour; most of the research currently done and published, *inter alia*, in novel journals like *Astrobiology* or *International Journal of Astrobiology*, as well as in the older ones like *The Origin of Life and Evolution of the Biosphere*, belongs to this category.

---

[18] E. Schrödinger, *What is Life?* (Cambridge: Cambridge University Press, 1944).

On a more general level, the task of astrobiology obviously depends on our ability to recognize life even in its strangest forms (i.e., those most removed from terrestrial experience). Contrary to the arbitrary assertions of some critics, the tradition of speculative thinking about alternative forms of life is as old as astrobiological thinking itself.[19] Speculations – now supplemented by computer simulations – concerning whether life can be based on silicon, fluor compounds, solid-state physics or even nuclear forces belong here and are likely to increase in number and quality in the future. The prevailing tendency even in the most conservative astrobiological circles has been to *increase* the robustness of life (e.g., in discoveries of various extremophiles), thus justifying a heightening of our expectations for the possibility of life elsewhere in the multiverse.

---

[19] For a classical example, see R. Shapiro and G. Feinberg, 'Possible Forms of Life in Environments Very Different from the Earth' in M. M. Hart and B. Zuckerman (eds) *Extraterrestrials: Where Are They?* (New York: Pergamon, 1982); and for a modern one, F.J Dyson, 'Looking for life in unlikely places: reasons why planets may not be the best places to look for life', *International Journal of Astrobiology* 2, 2003: 103-10. For a very early SF treatment of the theme, see J.-H. Rosny, 'Another World', in COLLAPSE III, 2007: 255-306.

A particular form of surveying is embodied in research on *artificial life* (Alife). From a rather eccentric game of computer scientists (albeit one with august ancestry, with von Neumann), it has become an important mainstream research discipline with wide-ranging influence and an increasing number of applications within fields such as evolutionary computation, cellular automata, genetic algorithms and even evolutionary art.[20] It is often stated that the goal of Alife is to *recreate* biological systems in a digital environment, but there are at least some distinguished researchers, such as ecologist and computer scientist Thomas Ray, who claim that such experiments are actually *creating* a new kind of life.[21] Clearly, if this strong A-life thesis turns out to be correct, this will have important epistemological implications for cosmology as well, since numerical experiments such as Ray's would make the sea shores of the Archipelago amenable to much more precise probing – something alike to the revolution of Gerardus Mercator and Abraham Ortelius in cartography in the 1560s.

Finally and most pertinently to our goal, we can ask, with Tegmark:[22] What are the minimal conditions for a physical environment containing intelligent observers? Tegmark lists three basic conditions, namely (1) complexity, (2) predictability, and (3) stability. (He imposes them on mathematical structures describing arbitrary physical laws, in accordance with his 'Platonist' position on the relationship between mathematical and physical worlds; but the usage of these criteria does not really hinge on this philosophical viewpoint.)[23] The first necessary condition is almost self-evident: even the most ardent physicalists are unlikely to deny that an excessively high level of complexity is the reason why, among other things, we have not yet managed to create living or intelligent beings in the laboratory. The other two criteria are meaningful if we consider the operation of measurement by which knowledge is received by observers, an operation which requires both that the results do not fluctuate too much in the past or the future, to preclude the use of inference from past experience, and that habitable conditions exist at least during measurements. Of course, these are necessary, but not sufficient criteria for habitability. The search for sufficient criteria, and thus for the outlines of the Archipelago, continues.

[22] M. Tegmark, 'Is the "Theory of Everything" Merely the Ultimate Ensemble Theory?', op. cit.

All this (and, arguably, much else) constitutes an 'extended mandate' of astrobiology – and one immediately answering all the conventional criticisms:[24] Almost by definition, it 'looks outward to the general, rather than inward to the particular'. It will, hopefully, provide a much more satisfactory answer to one of the perennial problems of science – Schrödinger's question – in the most general multiverse context.

---

[23] Even more precisely, Tegmark uses the term 'self-aware substructure' in order to pose the problem as mathematical, since on the Platonist viewpoint an observer is nothing else than a part of a wider mathematical structure. But the same general reasoning about the criteria applies if we (i) regard observers as physical systems only approximated by mathematical descriptions, and (ii) have a particular physical mechanism of introducing variations (like the spontaneous symmetry breaking in inflationary cosmologies).

[24] E.g. J. Cohen, and I. Stewart, *What Does a Martian Look Like? The Science of Extraterrestrial Life* (Hoboken, NJ: John Wiley & Sons, 2002).

3. VOYAGES OF DISCOVERY

Geography and cartography would be senseless without an appropriate metric; in the terrestrial case, the units of length (such as kilometers and nautical miles) combined with the angular coordinates (such as longitude and latitude), provide us with a hugely successful description of any explored piece of landmass or ocean. The extension of our analogy to the cartography of the Archipelago of Habitability emphasizes the analogous role of changing various parameters of physics (including the very form of low-energy physical laws). Let us forget, for the purposes of this section, the issue of the altitude of points on an island (i.e. the degree of habitability) and suppose that we are dealing with a single-contour map. Classical anthropic arguments from fine-tuning amassed significant empirical evidence that we cannot change the parameters that describe our universe *very much*, at least as long as we keep other parameters constant.[25] For example, the initial low entropy of our Big Bang seems excessively fine-tuned,[26] as does the amplitude of the primordial density perturbations seen as anisotropies in the cosmic microwave background.[27] This would mean that our island is a rather small one, since even small changes in any single coordinate (with other coordinates kept constant) would lead us quickly to the ocean shore. In such a situation, it seems natural that early anthropic thinkers concluded that our island is the only one in existence. They were wrong, but not because of some ulterior and heinous agenda, as it is sometimes implied by opponents of anthropic reasoning; it was perfectly reasonable for them to think so – we might compare their rationality to that of a hypothetical ancient philosopher of Easter Island, pondering the huge ocean surrounding his home.

---

[25] For compilation of the evidence up to mid-1980s see J.D. Barrow and F.J. Tipler, *The Anthropic Cosmological Principle* (NY: Oxford University Press, 1986). An updated review is C. J. Hogan, 'Why the Universe is Just So', *Reviews of Modern Physics* 72, 2000: 1149-61.

[26] R. Penrose, *The Emperor's New Mind* (Oxford: Oxford University Press, 1989); M. M. Ćirković, 'The Thermodynamical Arrow of Time: Reinterpreting the Boltzmann-Schuetz Argument', *Foundations of Physics* 33, 2003: 467-90.

But contemporary sailors of the Archipelago have been able to refute this prejudice. In his often cited and almost as often poorly understood study, Aguirre[28] finds a 'cold' Big Bang model – a counterfactual one with low entropy-per-baryon in comparison to our actual Big Bang – which is habitable even according to the very high standards posed by the *terrestrial* kind of life. This type of universe is also capable of producing structure, such as galaxies and stars, as well as the chemical building blocks of life; and in such an astrophysical environment, so drastically different from our own in other respects, there is sufficient time for chemical and biological evolution. Some opponents of anthropic reasoning hailed this result as a long-awaited refutation of the alleged 'anthropocentrism' of such reasoning.[29] Whereas what Aguirre does, in fact, is to discover another habitable region in the parameter space – another island of habitability!

---

[27] M. Tegmark and M. J. Rees, 'Why is the Cosmic Microwave Background Fluctuation Level 10^{-5}?', *Astrophysical Journal* 499, 1998: 526-32.

[28] A. Aguirre, 'The Cold Big-Bang Cosmology as a Counter-example to Several Anthropic Arguments', *Physical Review D* 64, 2001, 083508.

While this is a seminal result, it is a far cry from being a 'refutation' or 'disproof' of anthropic reasoning. In fact, supporters of anthropic reasoning have every reason to cheer on Aguirre's bold exploratory voyage: It actually demonstrates that such exploration is meaningful, and that the question of probabilities of observing various parameter values can, at least in principle, be answered quantitatively and operationally. The role of astrobiology sketched in §2 above finds some expression in the endnote of Aguirre's paper, which states:

> I have assumed that the number of independent measurements in a subuniverse is proportional to the number of suitable stars, neglected such effects as, for example, high metallicity leading to more planets upon which multiple civilizations might arise in a single solar system. I have also neglected factors like extinction-causing impacts, radioactivity-induced plate tectonics, etc., which are possibly but not clearly necessary for the evolution of observers.[30]

All these (and many other) factors clearly belong to the domain of astrobiological research. Thus, any elaboration of the classical anthropic arguments, no matter whether supportive or undermining, straightforwardly necessitates the use of astrobiological knowledge. And Aguirre shows that we need such knowledge from our universe (and our experience), even when dealing with other, disconnected parts of the Archipelago.

---

[29] Cohen and Stewart, *What Does a Martian Look Like?*, op.cit.; see also 'Alien Science: Interview with Jack Cohen and Ian Stewart', this volume; L. Smolin, 'Scientific alternatives to the anthropicprinciple' (2004), preprint at http://arXiv:hep-th/0407213.

[30] Aguirre, 'The Cold Big-Bang Cosmology', op. cit.: n. 18.

But Aguirre's is not the only island different from our home island discovered so far. In fact, the island discovered by Harnik, Kribs, and Perez[31] is both larger (in both senses discussed above) and more remote from our home universe: They investigated nothing less than a set of conceivable universes without weak interaction ('weakless' universes). Before engaging in the analysis, they explain the methodology:

> We do not engage in discussion of the likelihood of doing simultaneous tunings of parameters nor the outcome of statistical ensembles of parameters. These questions are left up to the ultraviolet completion, such as the string landscape, which is outside of the scope of effective field theory. Instead, we are interested in 'running the universe forward' from a time after inflation and baryogenesis through billions of years of evolution. We will exploit the knowledge of our Universe as far as possible, adjusting standard model and cosmological parameters so that the relevant micro- and macro-physical outcomes match as closely as possible. We emphasize that this is really a practical matter, not one of principle, since any significant relaxation of the 'follow our Universe' program would be faced with horrendously complicated calculations. Put another way, there is probably a wide range of habitable universes with parameters and structures that look nothing like our Universe. For us, it

---

[31] R. Harnik, G. Kribs, and G. Perez, 'A universe without weak interactions', *Physical Review D* 74, 2006, 035006.

> is enough to find one habitable weakless universe about which we can make the most concrete statements, hence matching our Universe as closely as possible.

This truly looks like a bold sailors' manifesto! The difficulties bound to be encountered by any stray explorer in the dangerous waters ('horrendously complicated calculations') are explained, and the independence of the basic approach to the form of the multiverse (i.e. string landscape or any other) explicated. This makes the results of the study still more impressive, since they find at least a single piece of rock above the water in the midst of the ocean – an apparently habitable universe missing so crucial an ingredient of our world as one of the four fundamental low-energy interactions. Whether this is just a rock protruding from the waters or a tip of much larger island is unclear at present; Harnik et al. honestly admit that much.

Why, then, do these authors repeatedly perceive themselves as refuting or undermining anthropic arguments? The reasons are at least twofold. First, most anthropic arguments in the literature (like the one on setting of the electroweak scale, criticized by Harnik et al.) are narrowly or even badly formulated. They are based on narrow-minded calculations of the effects of small (one order of magnitude or so) changes in a small number of parameters, and not on a true insight into the underlying physics, which could indicate the way in which multiple parameters could be varied – at least in principle – whilst retaining habitability. A clear parallel here is with the misguided 'rare Earth' arguments[32] in astrobiology of the form: 'if there were no

---

[32] Cf. P. D. Ward and D. Brownlee *Rare Earth: Why Complex Life Is Uncommon in the Universe* (New York: Springer, 2000).

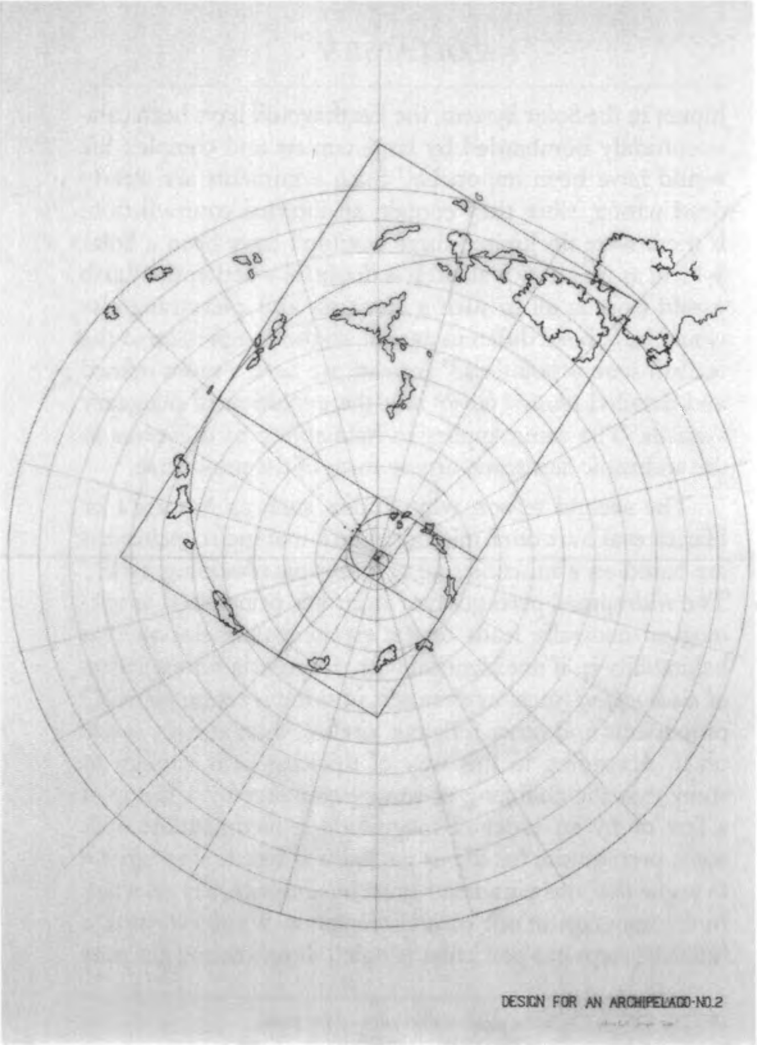

Figure 3. Charles Avery, *Untitled (Design for an Archipelago)* (2008), illustrating both the central metaphor and the possibility of 'deeper' mathematical regularities (here, the logarithmic spiral) underlying the seemingly random position of habitable regions. This is especially appropriate for Platonist multiverses such as Tegmark's, ultimately completely determined by overarching mathematical structures. (Image courtesy of the artist).

Jupiter in the Solar System, the Earth would have been catastrophically bombarded by large comets and complex life would have been impossible.' Such arguments are clearly dead wrong, since they contain an internal contradiction: If there were no Jupiter, there wouldn't have been a Solar System as we know it at all! It is doubtful whether the Earth would exist at all in such a scenario, and everything else would have been different as well, so the comparison to the realistic case is pointless.[33] Instead, we need a more refined and detailed *physical insight* into the evolution of planetary systems. The same applies to habitability of universes in the anthropic landscape or any form of the multiverse.

The second reason why studies such as Aguirre's or Harnik et al.'s are often misconstrued is that such conclusions are based on a misconstrual of anthropic reasoning itself.[34] The widespread perception of anthropic principle(s) as teleological naturally leads to the erroneous conclusion that habitability is, if not identical with the criteria for evolution of *homo sapiens* (such an extremist position is relegated to ID proponents and other religious circles), than at least *centred* on it. According to this way of thinking, it is enough to show that the changing of some parameter by a factor of a few or by an order of magnitude is incompatible with some prerequisite for life as we know it (read: *homo sapiens*) to argue that this parameter must be anthropically selected. In the language of our central metaphor, if you can walk a hundred steps in a particular (single!) direction and get your feet wet, that is enough to prove that you live on an island. This logic is anthropocentric and flawed; it has nothing to do with the real meaning of anthropic reasoning. It may well be true that we are indeed living on an island (after all, even Eurasia can be regarded as a rather large island!), but the justification for it is wrong. And yet, it is appealing for the same extrascientific reasons we shall return briefly to in the next section: viz., the rear-guard actions of both positivists and teleologists, leading to a widely accepted anthropocentric 'noble lie'.

---

[33] I thank Chris Chyba for pleasant discussion of this point.

[34] See, e.g., Cohen and Stewart, *What Does a Martian look Like?*, op. cit.; and Quentin Meillassoux, 'Potentiality and Virtuality', in R. Mackay (ed.) **Collapse** II: 55-81 (cf. Meillassoux's comment in **Collapse** IV: 441).

In a more general sense, studies such as that of Chavanis on white dwarf stars in an arbitrary number of dimensions,[35] or Adams on stellar evolution with unconventional parameters,[36] are part of the research helping us elucidate the Archipelago. We do not perceive any direct connection between us and white dwarfs at present, but the elegance and simplicity of the problem of such physical objects in D dimensions gives us a feel for the approaches and ways of thinking necessary to sketch out the cartographical task. Obviously, interest in this sort of research has increased significantly in the last couple of years – we might be on the verge of a true Age of Multiverse Exploration!

4. ANTHROPIC SELECTION AND DETRACTION

Steven Weinberg claimed to have predicted the existence of a small positive cosmological constant in the anthropic manner more than a decade before its actual observational discovery.[37] This theoretical success opened the way for dramatic expansion of anthropic arguments in cosmology. In the current cottage-industry of multiverse predictions in theoretical physics, a special role is reserved for the equation giving a probability that some observer anywhere in the multiverse measures a feature *X*:[38]

[36] F. C. Adams, 'Stars in other universes: stellar structure with different fundamental constants', *Journal of Cosmology and Astroparticle Physics* 08, 2008: 010.

$$p(X) = \frac{\sum \sigma_n (X) V_n \rho_n^{\text{obs}}}{\sum V_n \rho_n^{\text{obs}}}, \tag{1}$$

where the index *n* labels all possible vacuum states (all different low-energy '*physicses*' or different universes); in current versions of string theory there is a finite number of such states, although it is huge (10^{500} or so; see Susskind 2003), but in principle it could be infinite. The latter case could pose some interesting problems in the theory of probability,[39] but in general will not preclude the usage of Equation (1) with appropriate weightings, V_n is the spacetime volume belonging to the universe *n*, ρ_n^{obs} is the density of observers in the same universe, and

$$\sigma_n = \begin{cases} 1, \text{ if universe } n \text{ has property } X \\ 0, \text{ otherwise} \end{cases} \tag{2}$$

In principle, V_n is calculable from our understanding of cosmological physics, although in weird enough universes it might be impossible to calculate in practice (or at least in finite time available to human cosmologists!). It is also likely to be infinite in some or most of the universes, so some appropriate weighting procedure is certainly necessary. But, of course, the biggest uncertainty comes from the quantity ρ_n^{obs}, the density of intelligent observers. It is usually assumed to be proportional to the density of galaxies, the latter being the main features of the structure of our own universe. But this is at best uncertain, and at worst fantastically wrong for islands outside of our own home island. Obviously, more sophisticated astrobiology is needed here.

---

[38] See e.g., S.M. Carroll, 'Is Our Universe Natural?', *Nature* 440, 2006: 1132-36.

[39] Cf. J.D. Hamkins and B. Montero, 'Utilitarianism in Infinite Worlds', *Utilitas* 12, 2000: 91-96; Tegmark, 'The Mathematical Universe', op. cit.

How can the concept of the Archipelago of Habitability help us elucidate Equation (1)? Even very cursory thinking points the way toward what I shall dub 'altitude weighting': Obviously, even islands of identical shape on the map can have vastly different habitabilities – the universes in two groups could have a vastly different density of observers. We have thus far discussed only surface coordinates of islands in the Archipelago; but their essential property (which makes them islands) is their altitude profile. Very high points (analogues of the volcano peaks of the Hawaii islands) represent sets of parameters describing extremely bio-friendly universes, in contrast with bare rocks protruding from the waters, where lifeforms are possible but unlikely or very rare. The same pertains to intelligent observers: regions of high altitude will contain the predominant fraction of the entire set of observers in the multiverse. These regions correspond to high values of ρ_n^{obs} in such regions of the parameter space.

Thus, in order to make anthropic arguments cogent against the background of the Archipelago, we need to weight universes by their 'altitude', i.e. the measure of habitability. Clearly, this is a task for astrobiology in the widest sense: As discussed above, the very definition of the Archipelago is contingent upon resolving the issue of criteria for life to arise in a naturalistic manner. But in order to get the altitude profile, we need much more further effort – we need at least some hold on the emergence and dynamics of intelligent observers, traditionally the province of SETI studies (and the recreational discourse of SF books and movies). On the other hand, there is no discontinuity here: by studying already 'traditional' astrobiological themes like the Galactic Habitable Zone,[40] we expect to survey viable SETI targets and assess the density of extraterrestrial civilizations, even if some specific modifications are made when we consider intelligent observers rather than just complex lifeforms.[41] Obviously, much further research needs to be done in that direction. But the encouraging news is that several approaches have been developed recently which encapsulate elements of the future whole picture, notably the counting of observer-moments discussed by Bostrom in philosophical terms,[42] and the counting of the number of possible observations in a particular universe devised by Starkman and Trotta in the physical domain.[43]

[43] G. Starkman and R. Trotta, 'Why Anthropic Reasoning Cannot Predict Λ', *Physical Review Letters* 97, 2006: 201301.

There seems to be an epistemological similarity between the proposal of weighting by the astrobiological description ('altitude' in terms of my central metaphor) and Trotta's suggestion[44] that a 'fully Bayesian approach' could resolve the difficulties with anthropic arguments, especially the lack of universal weight criterion for ρ_n^{obs}.

In practice, this task is enormous; perhaps generations of astrobiologists will pass before we get close to quantitative precision. But the enormity of the task should not detract from the fact that it is a well-defined problem from the start. If anything, it should demonstrate how utterly wrongheaded is the classical criticism that the anthropic reasoning is a 'lazy man's approach to science'.[45]

In the remainder of this section, I shall explore some of the more conventional criticisms of anthropic reasoning and discuss how the metaphor of the Archipelago may help us refute or undermine them.[46]

Yepes (eds), *2nd International Conference on The Dark Side of the Universe, AIP Conference Proceedings* 878, 2006: 323-29 (preprint at http://arXiv:astro-ph/0610330).

[45] H. R. Pagels, 'A Cozy Cosmology', in J. Leslie (ed.), *Modern Cosmology & Philosophy* (Amherst: Prometheus Books, 1998), 180-86.

[46] I am skipping more bizarre anti-anthropic complaints that occasionally surface in the literature, an example being the charge that 'anthropic principle' is a misnomer (J. Mosterín, 'Anthropic Explanations in Cosmology,' in Hajek, Valdés & Westerstahl [eds], *Proceedings of the 12th International Congress of Logic, Methodology and Philosophy of Science* [Amsterdam: North-Holland Publishing], after many others). While it might be formally true, as Carter and others readily admitted, it hardly advances discussion of real issues involved. Being, in principle, sympathetic to a programme of excising misnomers from the scientific discourse, may I humbly ask that interested philosophers start with concepts such as 'Hubble's constant', 'planetary nebulae', 'forbidden spectral lines', or even 'quark colours' and 'flavours'?

4.1. BETRAYAL OF THE ENLIGHTENMENT?

There is a rather strange tendency in some scientific and philosophical circles to regard anthropic reasoning as a sort of 'betrayal' of the allegedly sacrosanct traditions of scientific explanation dating from the times of Galileo and Newton. Although this form of criticism has never been clearly and unambiguously formulated, it haunts many recent discussions.[47] Roughly, it alleges that we should rationally explore nature as seen from a completely neutral and immobile 'Archimedean' point – not as real, physical beings evolved through various processes of physical, chemical and biological evolution, but as disembodied abstract observers. Only the former viewpoint, suggest these researchers, yields true causal explanations and satisfies the overall goals of science. Anthropic reasoning does not conform to this model and, consequently, 'has no place in physics or cosmology'.[48] In my view, this is entirely wrong on several counts, including some purely epistemological ones, dealing with the nature of explanation of contingent facts, though I cannot enter this complex topic here.

Instead, I would like to point out that such a rear-guard positivist attitude is in itself bound to end either in contradiction or in mysticism. Are observers natural? It is somewhat surprising to see that the same critics of anthropic reasoning tend to believe in physicalist explanations of mental phenomena, including observership itself. This makes the criticism of anthropic reasoning somewhat close to hypocrisy: If observers are part of the nature to be studied, how can one justify ignoring their properties? Should not they be regarded as parts of the wholeness of reality that is to be rationally and empirically explained? Quite contrary to the detractors' assertions, the anthropic programme of elaboration of observation selection effects – of outlining the properties of the Archipelago of Habitability, in the terms of our metaphor – is the continuation of the Copernican revolutionary spirit in overcoming the apparent specialness not only of the Earth and of life on it, including humans, but of the very physical laws, associated mathematical structures, and our universe in general.

---

[47] See, e.g., L. Smolin *The Life of the Cosmos* (Oxford: Oxford University Press, 1997), 'Scientific alternatives to the anthropic principle', (2004), preprint at http://arXiv:hep-th/0407213, and *The Trouble with Physics* (New York: Houghton Mifflin, 2006); Pagels, 'A Cozy Cosmology', op. cit; J. Mosterín, 'The Anthropic Principle in Cosmology: A Critical Review', *Acta Institutionis Philosophiae et Aestheticae* 18, 2000: 111-39, 'Anthropic Explanations in Cosmology', op. cit.; and Quentin Meillassoux, 'Potentiality and Virtuality', op. cit.

[48] Pagels, 'A Cozy Cosmology', op. cit.

What is really betrayed here – and with good reason – are relics of the Cartesian dualism which underlay the mechanistic philosophy of classical physics for centuries, as well as positivist attitudes in the last century; that is, until modern science progressed sufficiently to tackle the most general questions of the origin of universe, life and intelligence. To approach problems dealing implicitly or explicitly with the properties of observers (e.g., problems in quantum physics or cosmology or astrobiology) in the same manner as, for instance, classical physicists studied the motion of a pendulum or the planet Uranus is not just epistemologically naïve – it is plain wrong.

4.2. HOW COZY IS OUR UNIVERSE?

A charge occasionally brought against anthropic reasoning (especially in older, pre-Weinberg literature) is that its proponents blithely assume that our universe is at the peak of habitability, i.e. 'the best of all worlds' in terms of life and intelligence, although it is clear that one could conceive a universe significantly friendlier for life than our own.[49] While such panglossianism might indeed have been true for the now discarded teleological construals of the anthropic principle(s), there is no reason to retain any such misperceptions any more.

On the contrary, it is clear from the idea of 'altitude weighting' sketched above how easily the Archipelago view can resolve our difficulties. There is no *a priori* reason for us to believe that we are at the top mountain peak of our own island, still less of the entire Archipelago. One may sympathize with Tegmark's view that the requirement that '[o]ur observations are the most generic ones that are consistent with our existence' is a useful prediction in the multiverse,[50] but its meaning depends on the qualification of 'our' type of observer (human? human-like? planetary? carbon-based? evolved?, etc.). We cannot say in advance whether our home-island is mostly flat or very rugged. Our real altitude and the height profile of our vicinity is a matter for rational and empirical investigation; we should conduct many numerical experiments and calculate how far in various directions we are from both the peak(s) and the shores of our home island. Suppose, for the sake of simplicity, that there is just a single peak, corresponding to the most habitable universe in our region. Determining our distance from the peak is then equivalent to answering the question of how much various parameters would need to be simultaneously changed in order for the number of predicted observers to be increased. Determining our distance from sea level is equivalent to answering the question of how much various parameters would need to be simultaneously changed in order for the universe to cease to be habitable. We may have different intuitions as to the answers to these questions, but the bottom line is that this is a problem to be answered by quantitative astrobiological modelling.

---

[49] Echoes of this position can be found in, e.g., J. Maynard-Smith and E. Szathmáry, 'On the likelihood of habitable worlds', *Nature* 384, 1996: 107.

[50] M. Tegmark, 'Is "The Theory of Everything" Merely the Ultimate Ensemble Theory?', op.cit.

4.3. IMPRECISELY DEFINED SHORES?

Klee laments the fact that anthropic arguments are numerically imprecise, often by an order of magnitude or more, and stretch the meanings of terms 'of the same order of magnitude' or 'of similar order of magnitude'.[51] He calls this 'mathematical sharp practice' and concludes that it is usually motivated by extrascientific, namely theistic, reasons. Apart from the old moral about taking up the sword and perishing by it,[52] this criticism sounds like a whiggish charge that Pedro Álvares Cabral or Fernando de Magallanes did not use precise maps; their errors in navigation were often an order of magnitude or more larger than what we in the GPS age know about the *correct* geography. Are their discoveries any the less appreciable for that undeniable fact? Do we mock them – or do we rather celebrate their achievements, while emphasizing the simple means they had at their disposal? Understanding that we are at the very beginning – an overstatement, if anything – of the exploration of the Archipelago of Habitability should lead us naturally to expect large errors in our positioning of its shores – how could it be otherwise?

4.4. THE PROBLEM OF SWARMING ADVANCED OBSERVERS

In a thought-provoking paper, Olum argues that 'a straightforward application of anthropic reasoning and reasonable assumptions about the capabilities of other civilizations predicts that we should be part of a large civilization spanning our galaxy.'[53] This has been quoted by Carroll[54] and others as an instance of anthropic reasoning giving unacceptable results even within a single universe. Starting from the assumption of an infinite universe (following from the inflationary paradigm), Olum conjectures that there are civilizations much larger than ours (consisting of about 10^{10} observers). Spatial extent and the amount of resources at the disposal of such large civilizations would lead, in principle, to much larger number of observers (for example, 10^{19} observers). Now, even if 90 percent of all existing civilizations are small ones similar to our own, anthropic reasoning suggests that the overwhelming probabilistic prediction is that we live in a large civilization. Since this prediction is spectacularly unsuccessful on empirical grounds, with the probability of such failure being about 10^{-8}, something seems clearly wrong here.

---

[53] K. Olum, 'Conflict between anthropic reasoning and observation', *Analysis* 64, 2004: 1-8.

[54] Carroll, 'Is our Universe Natural', op. cit.

There are several ways out of Olum's problem, as he himself points out. For instance, we may conceive of a future redefinition of the concept of 'observer' (e.g., in the 'hive-mind' scenarios popular in SF), which would skew the Bayesian factor and resolve the paradox. But even if we restrict ourselves to our universe, there are less strong medicines at our disposal. It can be shown that the knowledge of the particular present epoch, together with some rather uncontroversial astrophysical assumptions, is sufficient to undermine – or, more precisely, to *postpone* – the applicability of Olum's argument.[55] However, this way out may not be open when we generalize to the entire spacetime (understood in a sufficiently wide sense) of the Archipelago – in that case we should ask the question: 'Why we don't find ourselves in a universe where almost all observers belong to large civilizations?' Although this question has not been pursued thus far, one possible approach could be that such universes are strongly suppressed for some at present unclear reason (say, that the observer-moment count peaks strongly before a typical large civilization anywhere can develop). Obviously, this remains a problem for anthropic reasoning generalised to the multiverse in the spirit of Equation (1) above.

4.5. THE PROBLEM OF FREAK OBSERVERS

One of the recently discovered difficulties facing the application of anthropic reasoning to the multiverse is that of so-called freak observers, also called Boltzmann's brains.

---

[55] M. M. Ćirković, 'Too Early? On the Apparent Conflict of Astrobiology and Cosmology', *Biology and Philosophy* 21, 2006: 369-79.

Although prefigured by Price, Rees, Bostrom[56] and some other thinkers, it was explicitly posed in the 'disturbing' study of Dyson, Kleban, and Susskind[57] as a consequence of the new standard cosmology dominated by constant vacuum energy (positive cosmological constant). Such a cosmology leads asymptotically to a future-eternal de Sitter spacetime. This is equivalent (in the eschatological limit of future eternity) to a thermal state with a characteristic temperature $\sim 10^{-29}$ K. At first glance, such a low temperature coupled with the extreme dilution of matter at such late epochs is unlikely to yield anything interesting, but in fact like any thermal system, such a late vacuum will fluctuate at a nonzero rate per unit spacetime volume. And out of such fluctuations, across large eschatological time spans, complicated systems, e.g. intelligent observers, can arise, again at a nonzero rate. Since de Sitter spacetime is eternal, such 'freak observers' will be infinite in number (in fact, their production rate will exponentially increase with time) and will thus completely overwhelm 'normal' observers, like us, who emerged through physical, chemical, and biological evolution. Why, then, are *we* not freak observers?

Several recent publications show that the threat has been taken seriously. In particular, Page[58] argues that the simplest answer to the puzzle is that the future is finite and that our universe will vanish before Boltzmann's brains start to dominate the total observers' census. On a more optimistic note (at least from the point of view of non-freak observers), Carlip shows that the time variation of fundamental constants can lead to a small measure of freak observers,[59] and Vilenkin demonstrates that the same effect is achieved by the bubble nucleation in de Sitter vacuum under some fairly reasonable assumptions.[60]

[58] D. N. Page, 'The Lifetime of the Universe', *Journal of the Korean Physical Society* 49, 2006: 711-14 (preprint at http://arXiv:hep-th/0510003).

From the present point of view, the problem of freak observers is easily generalized to a multiverse, since de Sitter spacetime is usually regarded as the source of an inflationary self-reproducing fractal. A rather uncontroversial aspect of anthropic reasoning is that we need to suppress the measure of freak observers in the entire Archipelago (and, clearly, Page's recipe will not work for a multitude of universes) in order to explain our evolution and our ordered observations. Although this problem will require further work, the good news is that there are ways out, such as those indicated in Carlip's and Vilenkin's studies.

5. PROSPECTS FOR AN AGE OF EXPLORATION?

In this essay, I have argued that the bridge between cosmology and particle physics on one side and astrobiology (and certain other 'mundane' disciplines, like artificial life, evolutionary theory, and so on) on the other, can be achieved through an exploration of cosmological parameter space. The Archipelago of Habitability – the set of habitable domains in the multiverse – seems to be a useful metaphor which directs our efforts towards an elucidation of the relationship between astrobiology and cosmology in a wider perspective. It offers directions for tight interdisciplinary collaboration between scientists interested in the properties of life, and those interested in the grand-scale structure of physical reality. It also offers great opportunities for philosophers – notably, the opportunity to generalize classical anthropic reasoning to the entire Archipelago, where all teleological and other unnecessary baggage is explicitly discarded. The relationship between the Archipelago and other multiverses containing intelligent observers considered in both philosophical[61] and scientific literature remains to be elaborated.

---

[60] A. Vilenkin, 'Freak observers and the measure of the multiverse', *Journal of High Energy Physics* 01, 2007: 092.

I have also attempted to argue that we may expect a true Age of Exploration of this Archipelago. Is this taking a metaphor too far? Not necessarily, even beyond Borges' idealistic statement – following Chesterton – that a really good metaphor cannot be taken too far; considering how dramatically the informatic revolution has changed our thinking about 'simulated' vs. 'real' worlds, it would be premature to claim that theoretical research on other habitable universes is any more intrinsically speculative than the very concepts of 'computer virus' or 'genetic algorithm' or even 'quantum computer' were a quarter of century ago. At the dawn of the new millennium, not only studies on the observable consequences of the existence of other universes,[62] but also intriguing arguments on simulating

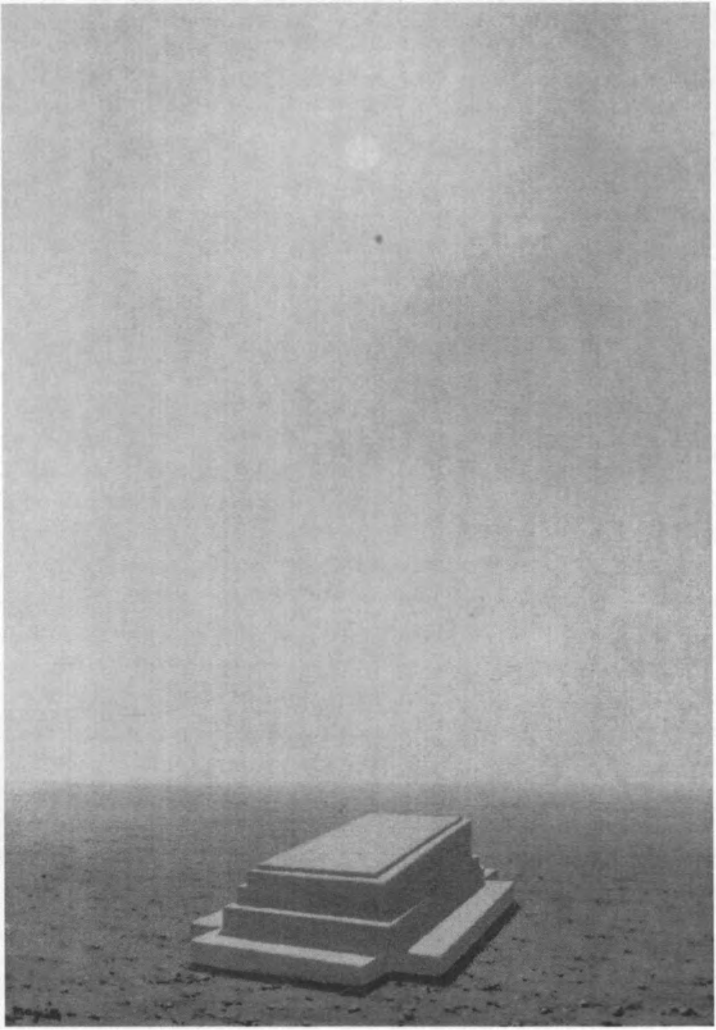

Figure 4. René Magritte's *The Beyond* (1938). The juxtaposition of an artifact and an apparently inhospitable planetary surface (remarkably prescient of our contemporary photographic images of the Martian surface) poses the age-old problem of the distinction between 'natural' and 'artificial' in a general context.

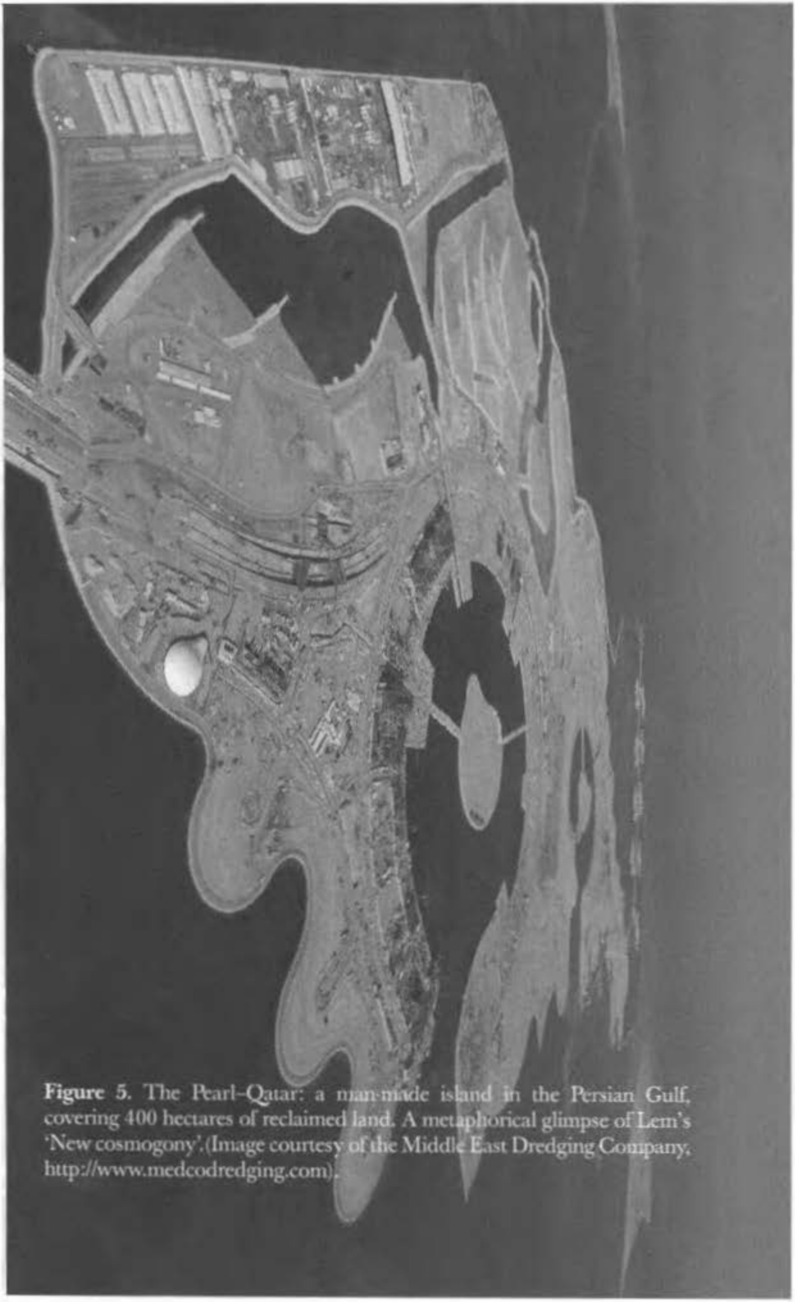

Figure 5. The Pearl–Qatar: a man-made island in the Persian Gulf, covering 400 hectares of reclaimed land. A metaphorical glimpse of Lem's 'New cosmogony'.(Image courtesy of the Middle East Dredging Company, http://www.medcodredging.com).

entire universes,[63] are threads of the same dynamic research activity – threads tightly entangled and intertwined, like the 'natural' and the 'artificial' in Magritte's painting. Further elucidation of this latter, perennial dichotomy could be an unexpected and welcome philosophical benefit.

Ultimately, I have used the concept of the observer here in a purely passive sense, in accordance with the only valid interpretation of anthropic reasoning as observational selection. But what about the vast future times for intentional action accorded to us (and other intelligent observers in the multiverse) by physical eschatology? Could the rules be changed, at least in principle and in the fullness of time, and parts of the landscape modified by intentional influence, like the build-up of artificial islands in today's world (figure 5)? Fortunately, at least two visionary pioneers strode, with giant steps, in that direction; we should keep silent in the huge shadows of Olaf Stapledon[64] and Stanislaw Lem.[65]

Where Are They?
Why I Hope the Search for Extraterrestrial Life Finds Nothing[1]

Nick Bostrom

When water was discovered on Mars, people got very excited. Where there is water, there may be life. Scientists are planning new missions to study the planet up close. NASA's next Mars rover is scheduled to arrive in 2010. In the decade following, a Mars Sample Return mission might be launched, which would use robotic systems to collect samples of Martian rocks, soils, and atmosphere, and return them to Earth. We could then analyze the sample to see if it contains any traces of life, whether extinct or still active. Such a discovery would be of tremendous scientific significance. What could be more fascinating than discovering life that had evolved entirely independently of life here on Earth? Many people would also find it heartening to learn that we are not entirely alone in this vast cold cosmos.

---

[1] First published in *MIT Technology Review*, May/June 2008: 72-7. Reprinted with permission.

But I hope that our Mars probes will discover nothing. It would be good news if we find Mars to be completely sterile. Dead rocks and lifeless sands would lift my spirit.

Conversely, if we discovered traces of some simple extinct life form – some bacteria, some algae – it would be bad news. If we found fossils of something more advanced, perhaps something looking like the remnants of a trilobite or even the skeleton of a small mammal, it would be *very* bad news. The more complex the life we found, the more depressing the news of its existence would be. Scientifically interesting, certainly, but a bad omen for the future of the human race.

How do I arrive at this conclusion? I begin by reflecting on a well-known fact. UFO-spotters, Raelian cultists, and self-certified alien abductees notwithstanding, humans have, to date, seen no sign of any extraterrestrial intelligent civilization. We have not received any visitors from space, nor have our radio telescopes detected any signals transmitted by any extraterrestrial civilization. The Search for Extra-Terrestrial Intelligent Life (SETI) has been going for nearly fifty years, employing increasingly powerful telescopes and data mining techniques, and has so far consistently corroborated the null hypothesis. As best we have been able to determine, the night sky is empty and silent – the question 'Where are they?' thus being at least as pertinent today as it was when Enrico Fermi first posed it during a lunch discussion with some of his physicist colleagues back in 1950.

Here is another fact: There are on the order of 100 billion stars in our galaxy alone, and the observable universe contains on the order of 100 billion galaxies.

In the last couple of decades, we have learnt that many of these stars have planets circling around them. By now, several hundred exoplanets we have discovered. Most of these are gigantic, but this is due to a selection effect: It is very difficult to detect smaller exoplanets with current observation methods. (In most cases, the planets cannot be directly observed. Their existence is inferred from their gravitational influence on their parent sun, which wobbles slightly when pulled towards a large orbiting planet; or alternatively by a slight fluctuation in their sun's perceived luminosity which occurs when it is partially eclipsed by the exoplanet.) We have every reason to believe that the observable universe contains vast numbers of solar systems, including many that have planets that are Earth-like at least in the sense of having a mass and temperature similar to those of our own orb. We also know that many of these solar systems are much older than ours.

From these two facts it follows that there exists a 'Great Filter'.[2] The Great Filter can be thought of as a probability barrier. It consists of one or more highly improbable evolutionary transitions or steps whose occurrence is required in order for an Earth-like planet to produce an intelligent civilization of a type that would be visible to us with our current observation technology. You start with billions and billions of potential germination points for life, and you end up with a sum total of zero extraterrestrial civilizations that we can observe. The Great Filter must therefore be powerful enough – which is to say, the critical steps must be improbable enough – that even with many billions of rolls of the dice, one ends up with nothing: no aliens, no spacecraft, no signals, at least none that we can detect in our neck of the woods.

---

[2] I borrow this term from Robin Hanson's 'The Great Filter – Are We Almost Past It?' (http://hanson.gmu.edu/greatfilter.html), a paper which presents an argument similar to the one expounded here.

Now, an important question for us is, just where might this Great Filter be located? There are two basic possibilities: It might be behind us, somewhere in our distant past. Or it might be ahead of us, somewhere in the millennia or decades to come. Let us ponder these possibilities in turn.

Consider first the possibility that the filter is in our past. This would mean that there is some extremely improbable step in the sequence of events whereby an Earth-like planet gives rise to an intelligent life form comparable in its technological sophistication to our contemporary human civilization. Some people seem to take it for granted that evolution of intelligent life on this planet was straightforward – lengthy, yes, complex, sure, yet ultimately inevitable or nearly so. Carl Sagan appears to have held this view; he once wrote that 'the origin of life must be a highly probable circumstance; as soon as conditions permit, up it pops!'[3] But this view might well be completely mistaken. There is at any rate hardly any evidence to support it. Evolutionary biology, at the moment, does not enable us to calculate from first principles how probable or improbable the evolution of intelligent life on Earth was. Moreover, if we look back at the history of life on this planet, we can identify a number of evolutionary transitions each one of which is a plausible candidate Great Filter.

---

[3] C. Sagan, 'The abundance of life-bearing planets', *Bioastronomy News* 7(4): 1–4.

For example, perhaps it is very, very improbable that even simple self-replicators should emerge on any given Earth-like planet. Attempts to create life in the laboratory by mixing water and gases believed to have existed in the early atmosphere on Earth have failed to get much beyond the synthesis of a few simple amino acids. No instance of abiogenesis has ever been observed.

The oldest confirmed microfossils date from approximately 3,500 million years ago, and there is tentative evidence that life might have existed a few hundred million years prior to that date, but no evidence of life before 3,800 million years ago. Life might well have arisen considerably earlier than that without leaving any traces. There are very few preserved rock formations this old and such as have survived have undergone major remoulding over the eons. Nevertheless, there is a period lasting several hundreds of millions of years between the formation of Earth and the first known life. The evidence is thus consistent with the hypothesis that the emergence of life required an extremely improbable set of coincidences, and that it took hundreds of millions of years of trial-and-error, of molecules and surface structures randomly interacting, before something capable of self-replication happened to appear by a stroke of astronomical luck. For aught we know, this first critical step could be a Great Filter.

Since we cannot rerun the history of life multiple times to obtain rigorous statistics, it is difficult to determine conclusively the 'difficulty' of any given evolutionary development. There are, however, some criteria that we can use to identify evolutionary transitions that are at least good candidates for being a Great Filter, i.e. that are both extremely improbable and practically necessary for the eventual emergence of intelligent technological civilization. One criterion is that the transition should have occurred only once. Flight, sight, photosynthesis, and limbs have all evolved several times here on Earth, and are thus ruled out. Another indication that an evolutionary step was very improbable is that it took a very long time for it to occur even after its prerequisites were in place. A long delay suggests that vastly many random recombinations had to be tried before one was found that worked. Perhaps several improbable mutations had to occur all at once in order to leap from one local fitness peak to another: the mutations might individually be deleterious and only fitness-enhancing when they occur together. (The evolution of *Homo sapiens* from one of our recent hominid ancestors, such as *Homo erectus*, happened rather quickly on geological timescales, so this step would be a relatively weak candidate for a Great Filter.)

The original emergence of life appears to meet these two criteria. As far as we know, it might have occurred only once and it might have taken hundreds of millions of years for it to happen even after the planet had cooled down sufficiently to enable a wide range of organic molecules to be stable. Later evolutionary history offers additional candidates for the Great Filter. For example, it took some 1.8 billion years for prokaryotes (the most basic type of single-cell organism) to evolve into eukaryotes (a more complex kind of cell with a membrane-enclosed nucleus). 1.8 billion years is a long time, and as far as we know eukaryotes evolved only once, making this transition an excellent possible Great Filter. Other strong candidates include the rise of multi-cellular organisms and sexual reproduction.

So one possibility is that the Great Filter is behind us. This would explain the absence of observable aliens. Why? Because if the rise of intelligent life on any one planet is sufficiently improbable, then it follows that we are most likely the only such civilization in our galaxy or even in the entire observable universe. (The observable universe contains approximately 10^{22} stars. The universe might well extend infinitely far beyond the part that is observable by us, and may contain infinitely many stars. If so, then it is virtually certain that there exists an infinite number of intelligent extraterrestrial species, no matter how improbable their evolution on any given planet. However, cosmological theory implies that, due to the expansion of the universe, any life outside the observable universe is and will forever remain causally disconnected from us: it can never visit us, communicate with us, or be seen by us or our descendants.)

The other possibility is that the Great Filter is after us, in our future. This would mean that there is some great improbability that prevents almost all technological civilizations at our current human stage of development from progressing to the point where they engage in large-scale space-colonization and make their presence known to other technological civilizations. For example, it might be that any sufficiently technologically advanced civilization discovers some technology – perhaps some very powerful weapons technology – that causes its extinction.

I will return to this scenario shortly, but first I shall say a few words about another theoretical possibility: that the extraterrestrials are out there, in abundance but hidden from our view. I think this is unlikely, because if extraterrestrials do exist in any numbers, it's reasonable to think at least one species would have already expanded throughout the galaxy, or beyond. Yet we have met no one.

Various schemes have been proposed for how an intelligent species might colonize space. They might send out 'manned' space ships, which would establish colonies and 'terraform' new planets, beginning with worlds in their own solar system before moving on to more distant destinations. But much more likely, in my view, would be colonization by means of so-called 'von Neumann probes', named after the Hungarian-born prodigy John von Neumann, who included among his many mathematical and scientific achievements the development of the concept of a universal constructor. A von Neumann probe would be an unmanned self-replicating spacecraft, controlled by artificial intelligence, capable of interstellar travel. A probe would land on a planet (or a moon or asteroid), where it would mine raw materials to create multiple replicas of itself, perhaps using advanced forms of nanotechnology. These replicas would then be launched in various directions, thus setting in motion a multiplying colonization wave.[4] Our galaxy is about 100,000 light years across. If a probe were capable of travelling at one-tenth of the speed of light, every planet in the galaxy could thus be colonized within a couple of million years (allowing some time for the bootstrapping process that needs to take place between a probe's landing on a resource site, setting up the necessary infrastructure, and producing daughter probes). If travel speed were limited to 1 percent of light speed, colonization might take twenty million years instead. The exact numbers do not matter much because they are at any rate very short compared to the astronomical time scales involved in the evolution of intelligent life from scratch (billions of years).

---

[4] This scenario was developed by Frank Tipler in 1981.

If building a von Neumann probe seems like a very difficult thing to do – well, surely it is, but we are not talking about a proposal for something that NASA or the European Space Agency should get to work on today. Rather, we are considering what would be accomplished with some future very advanced technology. We ourselves might build von Neumann probes in decades, centuries, or millennia – intervals that are mere blips compared to the lifespan of a planet. Considering that space travel was science fiction a mere half century ago, we should, I think, be extremely reluctant to proclaim something forever technologically infeasible unless it conflicts with some hard physical constraint. Our early space probes are already out there: Voyager 1, for example, is now beyond our solar system.

Even if an advanced technological civilization could spread throughout the galaxy in a relatively short period of time (and thereafter spread to neighboring galaxies), one might still wonder whether it would opt to do so. Perhaps it would rather choose to stay at home and live in harmony with nature. However, there are a number of considerations that make this a less plausible explanation of the great silence. First, we observe that life here on Earth manifests a very strong tendency to spread wherever it can. On our planet, life has spread to every nook and cranny that can sustain it: East, West, North, and South; land, water, and air; desert, tropic, and arctic ice; underground rocks, hydrothermal vents, and radioactive waste dumps; there are even living beings inside the bodies of other living beings. This empirical finding is of course entirely consonant with what one would expect on the basis of elementary evolutionary theory. Second, if we consider our own species in particular, we also find that it has spread to every part of the planet, and we have even established a presence in space, at vast expense, with the international space station. Third, there is an obvious reason for an advanced civilization that has the technology to go into space relatively cheaply to do so: namely, that's where most of the resources are. Land, minerals, energy, negentropy, matter: all abundant out there yet limited on any one home planet. These resources could be used to support a growing population and to construct giant temples or supercomputers or whatever structures a civilization values. Fourth, even if some advanced civilization were non-expansionary to begin with, it might change its mind after a hundred years or fifty thousand years – a delay too short to matter. Fifth, even if some advanced civilization chose to remain non-expansionist forever, it would still not make any difference if there were at least one other civilization out there that at some point opted to launch a colonization process: that expansionary civilization would then be the one whose probes, colonies, or descendants would fill the galaxy. It takes but one match to start a fire; only one expansionist civilization to launch the colonization of the universe.

For all these reasons it seems unlikely that the galaxy is teeming with intelligent life and that the reason we haven't seen any of them is that they all confine themselves to their home planets. Now, it is possible to concoct scenarios in which the universe is swarming with advanced civilizations every one of which chooses to keep itself well hidden from our view. Maybe there is a secret society of advanced civilizations that know about us but have decided not to contact us until we're mature enough to be admitted into their club. Perhaps they're observing us, like animals in a zoo. I don't see how we can conclusively rule out this possibility. But I will set it aside for the remainder of this essay in order to concentrate on what to me appears to be more plausible answers to Fermi's question.

A disconcerting hypothesis is that the Great Filter consists in some destructive tendency common to virtually all sufficiently advanced technological civilizations. Throughout history, great civilizations on Earth have imploded – the Roman Empire, the Mayan civilization that once flourished in Central America, and many others. However, the kind of societal collapse that merely delays the eventual emergence of a space-colonizing civilization by a few hundred or a few thousand years would not help explain why no such civilization has visited us from another planet. A thousand years may seem a long time to an individual, but in this context it's a sneeze. There are planets that are billions of years older than Earth. Any intelligent species on those planets would have had ample time to recover from repeated social or ecological collapses. Even if they failed a thousand times before they succeeded, they could still have arrived here hundreds of millions of years ago.

To constitute an effective Great Filter, we hypothesize a terminal global cataclysm: an existential catastrophe. An existential risk is one where an adverse outcome would annihilate Earth-originating intelligent life or permanently and drastically curtail its potential for future development. We can identify a number of potential existential risks: nuclear war fought with stockpiles much greater than those that exist today (maybe resulting from future arms races); a genetically engineered superbug; environmental disaster; asteroid impact; wars or terrorist acts committed with powerful future weapons, perhaps based on advanced forms of nanotechnology; superintelligent general artificial intelligence with destructive goals; high-energy physics experiments; a permanent global Brave-New-World-like totalitarian regime protected from revolution by new surveillance and mind control technologies. These are just some of the existential risks that have been discussed in the literature, and considering that many of these have been conceptualized only in recent decades. It is plausible to assume that there are further existential risks that we have not yet thought of.

The study of existential risks is an extremely important albeit rather neglected field of inquiry. But here we must limit ourselves to making just one point. In order for some existential risk to constitute a plausible Great Filter, it is not sufficient that we judge it to have a significant subjective probability of destroying humanity. Rather, it must be of a kind that could with some plausibility be postulated to destroy virtually all sufficiently advanced civilizations. For instance, stochastic natural disasters such as asteroid hits and super-volcanic eruptions are unlikely Great Filter candidates, because even if they destroyed a significant number of civilizations we would expect some civilizations to get lucky and escape disaster; and some of these civilizations could then go on to colonize the universe. Perhaps the most likely type of existential risks that could constitute a Great Filter are those that arise from technological discovery. It is not far-fetched to suppose that there might be some possible technology which is such that (a) virtually all sufficiently advanced civilizations eventually discover it and (b) its discovery leads almost universally to existential disaster.

So where is the Great Filter? Behind us, or not behind us?

If the Great Filter is ahead of us, we have still to confront it. If it is true that almost all intelligent species go extinct before they master the technology for space colonization, then we must expect that our own species, too, will go extinct before reaching technological maturity, since we have no reason to think that we will be any luckier than most other species at our stage of development. If the Great Filter is ahead of us, we must relinquish all hope of ever colonizing the galaxy; and we must fear that our adventure will end soon, or at any rate, prematurely. Therefore, we had better hope that the Great Filter is behind us.

What has all this got to do with finding life on Mars? Consider the implications of discovering that life had evolved independently on Mars (or some other planet in our solar system). That discovery would suggest that the emergence of life is not a very improbable event. If it happened independently twice here in our own back yard, it must surely have happened millions times across the galaxy. This would mean that the Great Filter is less likely to occur in the early life of planets and is therefore more likely still to come.

If we discovered some very simple life forms on Mars, in its soil or under the ice at the polar caps, it would show that the Great Filter must exist somewhere after that period in evolution. This would be disturbing, but we might still hope that the Great Filter was located in our past. If we discovered a more advanced life form, such as some kind of multi-cellular organism, that would eliminate a much larger stretch of potential locations where the Great Filter could be. The effect would be to shift the probability more strongly to the hypothesis that the Great Filter is ahead of us, not behind us. And if we discovered the fossils of some very complex life form, such as of some vertebrate-like creature, we would have to conclude that the probability is very great that the bulk of the Great Filter is ahead of us. Such a discovery would be a crushing blow. It would be by far the worst news ever printed on a newspaper cover.

Yet most people reading about the discovery would be thrilled. They would not understand the implications. If the Great Filter is not behind us, it is ahead of us.

So this is why I'm hoping that our space probes will discover dead rocks and lifeless sands on Mars, on Jupiter's moon Europa, and everywhere else our astronomers look. It would keep alive the hope for a great future for humanity.

Now, it might be thought an amazing coincidence if Earth were the only planet in the galaxy on which intelligent life evolved. If it happened here – the one planet we have studied closely – surely one would expect it to have happened on a lot of other planets in the galaxy also, which we have not yet had the chance to examine? This objection, however, rests on a fallacy: It overlooks what is known as an 'observation selection effect'. Whether intelligent life is common or rare, every observer is guaranteed to find themselves originating from a place where intelligent life did, indeed, arise. Since only the successes give rise to observers who can wonder about their existence, it would be a mistake to regard our planet as a randomly-selected sample from all planets. (It would be closer to the mark to regard our planet as though it were a random sample from the subset of planets that did engender intelligent life: this being a crude formulation of one of the sane elements extractable from the motley ore of ideas referred to as the 'anthropic principle'.)

Since this point confuses many, it is worth expounding it slightly. Consider two different hypotheses. One says that the evolution of intelligent life is fairly easy and happens on a significant fraction of all suitable planets. The other hypothesis says that the evolution of intelligent life is extremely difficult and happens perhaps only on one out of a million billion planets. To evaluate their plausibility in light of your evidence, you must ask yourself, 'What do these hypotheses predict that I should observe?' If you think about it, it is clear that both hypotheses predict that you should observe that your civilization originated in places where intelligent life evolved. All observers will observe precisely that, whether the evolution of intelligent life happened on a large or a small fraction of all planets. An observation selection effect guarantees that whatever planet we call 'ours' was a success story. And as long as the total number of planets in the universe is large enough to compensate for the low probability of any given one of them giving rise to intelligent life, it is not a surprise that a few success stories exist.

If – as I hope is the case – we are the only intelligent species that has ever evolved in our galaxy, and perhaps in the entire observable universe, it does not follow that our survival is not in danger. Nothing in the above reasoning precludes the Great Filter from being located both behind us *and* ahead of us. It might both be extremely improbable that intelligent life should arise on any given planet, and very improbable that intelligent life, once evolved, should succeed in becoming advanced enough to colonize space.

But we would have some grounds for hope that all or most of the Great Filter is in our past if Mars is indeed found to be barren. In that case, we may have a significant chance of one day growing into something almost unimaginably greater than we are today.

In this scenario, the entire history of humankind to date is a mere instant compared to the eons of history that lie still before us. All the triumphs and tribulations of the millions of peoples that have walked the Earth since the ancient civilization of Mesopotamia would be like mere birth pangs in the delivery of a kind of life that hasn't really begun yet. For surely it would be the height of naiveté to think that with the transformative technologies already in sight – genetics, nanotechnology and so on – and with thousands of millennia still ahead of us to perfect and apply these technologies and others that we haven't yet conceived of, human nature and the human condition will remain unchanged for all future times. Instead, if we survive and prosper, we will presumably develop into some kind of posthuman existence.

So this is why I conclude that the silence of the night sky is golden, and why, in the search for extraterrestrial life, no news is good news. It promises a potentially great future for humanity.

None of this means that we ought to cancel our plans to have a closer look at Mars. If the red planet ever harboured life, we might as well find out about it. It might be bad news, but it would tell us something about our place in the universe, our future technological prospects, the existential risks confronting us, and the possibilities for human transformation: issues of considerable importance.

It is impossible to know in advance what insights might be gleaned by applying the kind of careful and systematic study to such big questions that we apply every day to smaller and less consequential technological and scientific problems. There may be surprising arguments and ideas out there merely waiting to be discovered. Some of these might even turn out to have practical ramifications of such importance as to change our whole scheme of priorities. Perhaps the greatest benefit from the SETI program will result if it prompts thinking about these larger matters.

Theoretically, smart ambitious scholars could start thinking without waiting for such prompts. Expensive instruments, however, have a way of lending scientific status and respectability to a field of inquiry. Academics are keen to put as much distance as possible between themselves and the kooks and cranks that flock to these big questions. If large telescopes, NASA satellites, and complicated mathematical data analysis are involved, it becomes harder for outside observers to mistake the work for the ramblings of UFO-nuts and other crackpots. There may be no signals from space, yet those with their antennas tuned to more anthropomorphic wavelengths are sure to pick up a buzz of social signaling in people's attitudes towards the search for extraterrestrial beings. Such social background noise might in fact be one of the main obstacles to intellectual progress on many big-picture topics.

The Phoenix of Nature: Kant and the Big Bounce

Martin Schönfeld

For Fred Beiser, Mike Friedman, and Paul Eisenberg.[1]

There is a profound concept, the Phoenix of Nature, which deserves another look. Recent theoretical progressions are structuring information in startling ways. In light of this emerging information gestalt, a clarification of the Phoenix seems timely. The point is to advance towards a future integration of Kant.

The Phoenix of Nature appears in Kant's second book, Universal History of Nature and Theory of the Sky. It emerges only once, in part two, chapter seven (Academy Edition 1:321), but it can be understood as the idea that holds the book together. Universal History of Nature was published anonymously in 1755. Most printed copies were committed to the flames, supposedly accidentally, but probably intentionally. Its key idea was provocative. Kant's authorship contributed to his academic marginalisation until 1770.

---

1. Frederick C. Beiser (Syracuse) first pointed me towards the 'phoenix of nature' as a lacuna in Kant interpretation. Michael Friedman (Stanford) helped me to understand the scientific and heuristic relevance of Kant's thought. Paul Eisenberg (Indiana) patiently discussed with me my misgivings about Schopenhauer's criticism of Kantian philosophy. When I thought the Copernican turn precluded identification of Nature's deep structure, in Schopenhauer's or any other way, Paul Eisenberg encouraged me to look for a new reading of the Copernican turn, to integrate Kant's critical legacy with Kant's metaphysical and cosmological heirs. I thank them for inspiration.

The Phoenix is not part of conventional interpretations of Kant. It would be sensible for this situation to change, not least because this would allow mainstream scholarship to step out of its self-imposed isolation. Other research approaches, by workers in other disciplines, recognize the Phoenix and its implications. But a bridging of the disciplines, however timely, comes at a price. Philosophy will need to abandon its self-complacent, self-serving scepticism, deal at last with the patterns of outward reality, and become once more what it had been in Kant's enlightened day: *Weltweisheit* or world wisdom.

1. Conventional Neglect: Omitting the Phoenix

Historians of philosophy know that Kant wrote for nearly sixty years, from 1745 to 1802, but most of the scholarly attention is focused on what Lewis White Beck called the 'astonishing decade', the 1780s, which saw the publication of major works – the *Critiques*, the *Groundwork*, and *What is Enlightenment*, to name just a few.[2] The texts prior to the first *Critique*, the pre-critical writings, from 1746 to 1768, are by and large ignored. The critical works are available and taught in college. The early texts are not even read by most Kant experts. This is not because the early texts are juvenilia; they aren't: Kant wrote his first book, *Living Forces*, when he was in his twenties, the second, *Universal History*, in his thirties, and the third, *One Possible Proof-Ground for a Demonstration of Divine Dasein*, when pushing forty.

---

[2] 'I know of no way to describe the 1780s except to say that they were the astonishing decade.' L W Beck, *Early German Philosophy: Kant and his Predecessors* (Cambridge, Mass.: Harvard, 1969), 433.

The critical work has generated a mountain of commentary and analysis, while studies on the early texts are few and far between. Conventionally, we think of the critical Kant as belonging to a small handful of great thinkers, but we think of the early Kant as a flawed figure with an inconsequential body of work. The difference in reception between the two halves of the Kantian oeuvre could hardly be any starker.

The book on the Phoenix, *Universal History of Nature*, is neither well-known nor in print.[3] A literature search of the Phoenix will come up empty, at least as long as one scans bibliographies of Kant scholars. *Kant-Studien* has existed for a century, but its first article on that book appeared only a few years ago (2003). The article's title is just the book title ('Kants "Allgemeine Naturgeschichte und Theorie des Himmels" (1755)'), revealing how basic the scholarship has remained.[4] The paper falls in clear sections: on views before Kant, on the book, part I, part II, and on views after Kant.[5]

---

[3] There is an online translation, *Universal Natural History and Theory of the Heavens*, by Ian Johnston at Vancouver Island University, at http://records.viu.ca/~johnstoi/kant/kant2e.htm. The website, dated September 2008, and accessed October 2008, refers to a print edition by Richer Resources Publications (Arlington, VA), which, however, is not listed in the catalogue of the press. An earlier translation, also called *Universal Natural History and Theory of the Heavens*, by Stanley Jaki, was published by Scottish Academic Press (Edinburgh, 1981), and is out of print. The first translation, by William Hastie, titled *Kant's cosmogony, as in his essay on the retardation of the rotation of the earth and his natural history and theory of the heavens*, appeared in 1900; it was reprinted by Greenwood (New York, 1968), and University of Michigan Press (Ann Arbor, MI, 1969); both editions are no longer available. The Cambridge Edition of the Works of Immanuel Kant, ed. Paul Guyer and Allan Wood, has slated *Universal History of Nature* to appear in the volume *Natural Science*, ed. Eric Watkins, but this volume is nearly ten years overdue, and no fixed publication date has been set. In English, Kant's second book is not available in print.

[4] To my knowledge, there is no publication in *Kant-Studien* on Kant's first book, *Living Forces*, 1747, to date either.

[5] S. Lalla, 'Kants "Allgemeine Naturgeschichte und Theorie des Himmels" (1755),' *Kant-Studien* 94, 2003: 426-53.

The Phoenix isn't mentioned; neither is part III. After twenty-seven pages, the author concludes in the even-handed way that has become typical of conventional philosophy: Kant's approach was promising but also weird; his ideas were interesting but problematic; today it'd be tough to make scientific sense of them; their content is unverifiable, and this is probably a good thing.[6] Conclusions of this sort show two things: the scholarly consensus in first-rate philosophy journals – and the isolation of philosophy from scientific disciplines.

The differences between the early texts and the critical work come down to a contrast in perspectives. This contrast hinges on the so-called Copernican Turn. According to *Critique of Pure Reason* (B xvi) we tend to assume that concepts conform to objects, but doing so hasn't led to progress in metaphysics; so we might as well turn it upside down and assume the opposite, that *objects conform to concepts*, and see whether this would lead to progress. A corollary of the Copernican Turn is that any thing we take as an object is already an object conforming to concepts, which means an object seen is an object changed. When looking at things as they are in themselves we organize impressions into concept-conforming representations; it is these representations that we look at. Things in themselves are inaccessible. We are cognitive versions of King Midas: whatever we touch doesn't turn into gold but into appearance. Perception alters the perceived. And here's the rub: The early texts are precisely inquiries into things as they are in themselves. The Copernican Turn seems to rule such inquiry out and thus invalidate the early texts.

---

[6] Lalla, op. cit., 453: 'Rein retrospektiv hatte Kant einen vielversprechenden Ansatz geliefert, die Anfänge der eigenen Naturgeschichte explanativ einzuholen, um sich so ein solides Fundament für die Bestimmung aller sich aus dieser Urphase ergebenden Prozesse zu geben. Laplaces Glaube an die Vollständigkeit und die vollständige Verfügbarkeit aller dafür notwendigen Faktoren ist angesichts einer Quantenphysik nur noch schwer nachvollziehbar. Ob die Hypothese einer zeitlosen Determination des Gegebenen astronomisch sinnvoll ist (unabhängig davon, ob es anthropologisch wünschenswert ist), steht also heute, wie damals, buchstäblich in den Sternen.'

2. CHALLENGING THE COPERNICAN TURN: THE CONCEPTUAL ROUTE TO THE PHOENIX

But first appearances can be deceptive. That the Copernican Turn is an obstacle for grasping things as they are in themselves doesn't mean the obstacle is insurmountable. Yet that there may be a way around an invalidation of the early inquiries doesn't mean that the Copernican Turn was a failure either. It wasn't. It was a stunning success. The *Critique* changed discourse to such an extent that its year of publication divides what led up to it, Early Modern Thought, and what played out afterwards, the Age of Modernity. Kant's proposal settled the debate between rationalists and empiricists. Over the question of the roots of knowledge, rationalists stress the internal activity of the mind and appeal to mathematics as a case in point. Empiricists stress the external passivity of the mind and appeal to pretty much everything else. Kant integrated both views in a bigger picture: the mind is passively absorbing data and actively shaping appearances. The mind is passive and active. Cognition is an interactive process. Interactivity is the Midas Touch of perception, and since we perceive only what is absorbed-plus-shaped, the unshaped things in themselves elude our grasp. The conclusion of their indeterminacy is an effective weapon for social freedom. The critical work delivered the *coup de grace* to religious dogma. The elusiveness of the thing in itself means that transcendent truth is obscure and cannot be enforced. The critical insight was a milestone along the way toward more enlightened, secular, and open societies.

But freedom, in excess, is indulgence; there can be too much of a good thing. Ultimate religious truths are not ultimate natural patterns. Conceptually they are distinct. While the critical release from religious dogma is a lasting legacy, the critical suspension of metaphysical inquiry is not. Contrary to what one might expect, the Copernican Turn doesn't entail total inaccessibility of things as they are in themselves. There is a way to get to them, indirectly, through the environmental backdoor, so to speak.

Consider what things in themselves are: mind-independent material taken up in the cognitive process. While following the Copernican Turn we know *something* is mind-independent. Something is out there.

'Out there' are environmental structures that are mind-independent parts of reality. For a subject to *prevail* in such structures requires that the subject's representations match the real thing. If they fail to match up, the subject would be cognitively dysfunctional. It would bump into things, not procreate, be eaten, and soon die.[7] But a subject happily surviving in the mind-independent environment is different: it shapes absorbed sense data into appearances; it makes objects conform to concepts – but does so in such a way that the structure of its representation is an isomorphic echo of the structure of its environment. Conceptual form mirrors environmental form. For elementary evolutionary reasons, rational cognition makes objects conform to concepts that have worked out. Thus objects conform to concepts that fit. Things as they are in themselves are inaccessible and yet isomorphic mirrors of cognized appearances, at least in the case of surviving subjects. Accordingly the critical path leads to ultimate natural patterns after all. In this light, the Copernican Turn doesn't invalidate the results of Kant's early pursuits; it suspends them awaiting confirmation. For the concept at issue, the Phoenix, confirmation seems to have arrived.

---

[7] D Hoffman, in 'The Interface Theory of Perception,' forthcoming in *Object Categorization: Computer and Human Vision Perspectives*, ed. S. Dickinson et alia (Cambridge University Press), argues that, on evolutionary grounds, it is *not* the case that our senses have been shaped to the end of estimating true properties of the world, but instead that 'perceptions constitute a *species-specific user interface* that guides behaviour in a niche' (3). This approach seems to run counter to my isomorphism thesis, but I think it is compatible with my suggestion. Isomorphism does not mean identity. Our visual perception of a cave is distinct from its auditory perception by a bat. It seems hard to imagine what it is like to be like a bat, and what sonic picture of the cave a bat might represent to its mind. Clearly the sonic cave-representation is as much a species-specific user interface as a visual image of the cave by humans. However,

---

isomorphism means mapping by a rule. And while a sonic map differs from the visual map, both are related such that component information in either not only translates to the appropriate node in the respective other map, but also translates to the cave as it exists independent of any perceiver. As both maps work, humans walking in a cave are capable of avoiding stalagmites looming in the flashlight, just as it is possible for a bat flying there to swerve around the same stalagmites echoing its cries. In this way, the Copernican Turn fits to a cognitive realism. Things as they are in themselves emerge as isomorphic mirrors of cognized appearances, as mentioned. It should further be noted that this use of 'thing in itself' differs from the usage in Schopenhauer, for instance, who takes 'thing in itself' as referring to a universal quintessence, and not the individuated structure of nature. L. W. Beck, in the glossary to the third edition of *Critique of Practical Reason* (New York: Kessinger, 2004), xxv, adds a clarification that '*Ding an sich* is an expression Kant employs only once in the second *Critique*, his usual locution being *Ding an sich selbst*. According to Gerold Prauss (*Kant und das Problem der Dinge an sich* [Bonn, 1974]), the latter locution is adverbial rather than adjectival, and elliptical for "thing regarded as it is in itself". The distinction [...] suggests that there are two *kinds* of things, viz., appearances and things in themselves, whereas the second suggests that there is one kind of thing in two contexts (as it appears, and as it is regarded in itself)'. The isomorphism thesis I wish to submit concerns the 'latter' kind; thus suggesting a 'two-aspect' interpretation. The price my thesis pays is that its acceptance does interpretive violence to Kant such that a problem left unresolved according to the textual evidence would find an arguable resolution upon further thought.

3. A UNIVERSAL SINGLE RULE: THE PHOENIX

The Phoenix of Nature is the idea that all environmental structures are subject to the rule of rise and fall. Everything oscillates, from simplicity to complexity to simplicity, along a line of quasi-reincarnations. No matter how long winter lasts, there'll be another spring. Such is life. Such is nature. In fact, such are all natures. In the beginning of the chapter on the Phoenix, Kant notes:

> The Universe, with its immeasurable greatness, endless diversity, and beauty, which shines up at all angles, puts us in a state of silent wonder. And whenever the idea of all this perfection fires up the power of imagination, the understanding falls into a state of delight, as soon as one considers how so much splendour and grandeur flows from a single universal rule, in eternal and right tact.(1:306.16-23)[8]

Nietzsche praised the Pre-Socratic depth of *Universal History of Nature.*[9] Like Anaxagoras or Heraclitus, Kant suspects *ek-pyrosis*, the eternal recurrence of *world burn*. Thus rise follows fall follows rise. For Nietzsche, the shape of quintessence, Kant's Phoenix, is a 'kind of swinging', a 'sort of vibration,' which, slowed down, would look like a dancing mathematical figure or a moving formal frame.[10] The largest formal frame – the largest environment – is the Universe. In German, 'universe' is the *All*. This isn't a static background against which nature's dance plays out. The *All*, the background, itself is dance. It is a chain steadily swinging from trough to peak to trough, or from a prone state to an evolved state to a prone state. Some cosmologists call the Phoenix 'the Big Bounce'. Here's Kant's take on the Phoenix:

---

[8] Kant, *Werke* (Academy Edition), 1:306.16-23: 'Das Weltgebäude setzt durch seine unermeßliche Größe und durch die unendliche Mannigfaltigkeit und Schönheit, welche aus ihm von allen Seiten hervorleuchtet, in ein stilles Erstaunen. Wenn die Vorstellung aller dieser Vollkommenheit nun die Einbildungskraft rührt, so nimmt der Verstand andererseits eine andere Art der Entzückung ein, wenn er betrachtet, wie so viel Pracht, so viel Größe aus einer einzigen allgemeinen Regel mit einer ewigen und richtigen Ordnung abfließt.'

[9] Nietzsche, *Philosophie im tragischen Zeitalter der Griechen* (*Philosophy in the Tragic Age of the Greeks*), § 17, in *Sämtliche Werke: Kritische Studienausgabe*, ed. G Colli, M Montinari (Munich/Berlin: DTV/De Gruyter 1980), 1:865.

> The Phoenix of Nature burns himself up only to return from his ashes, come back to life, and be young again. If we now follow the Phoenix through all infinity of time and space, and if we see how Nature, even in the aspect of decay and obsolescence, is not depleted of raw emergence; if we see how, at the other edge of creation and in the realm of unformed, raw matter, Nature proceeds with steady steps toward expansion of the plan of Divine unfolding and fills all time and all space with its miracles – if one sees all this, then the mind, pondering such vistas, will sink into deep wonder. (1:321.13-22)[11]

Between remarks on universal rule and the Phoenix, Kant details the relation of emergence and entropy:

---

[10] Nietzsche, *Werke*, 1:866.2-4: 'eine bewegte mathematische Figur [...] eine Art der Schwingung'.

[11] Kant, *Werke* (Academy Edition), 1:321.13-26: 'Wenn wir diesen Phönix der Natur, der sich nur darum verbrennt, um aus seiner Asche wiederum verjüngt aufzuleben, durch alle Unendlichkeit der Zeiten und Räume hindurch folgen; wenn man sieht, wie sie sogar in der Gegend, da sie verfällt und veraltet, an neuen Auftritten unerschöpft und auf der anderen Grenze der Schöpfung in dem Raum der ungebildeten rohen Materie mit stetigen Schritten zur Ausdehnung des Plans der göttlichen Offenbarung fortschreitet, um die Ewigkeit sowohl, als alle Räume mit ihren Wundern zu füllen: so versenkt sich der Geist, der alles dieses überdenkt, in ein tiefes Erstaunen'. For the translation above, note that I read *sie* ('she,' 1:321.16) as denoting nature.

It appears that the end, fated to the worlds as to all matters natural, is subject to some law. Recognizing this law will lend the theory a new touch, a touch of rightness. By this law, the end touches those worlds closest to the cosmic centre first, just as conception and organization had first started next to this centre. From there, doom and destruction radiate outward step by step in ever farther reaches from the centre. Through general dissipation of motion, the whole universe, having completed its period, will eventually be buried in uniform chaos. Yet Nature on the other side, at the opposite edge of the evolved cosmos, is busy steadily spawning worlds from the raw stuff of scattered elements. Nature on one side decays at centre. Nature on another side is young and fertile in new creations. So the evolved cosmos is placed in between, bounded by limits on either side – the ruins of destroyed nature, and a chaos of a still unformed nature. And if we imagine that (as would be likely) the time-span of a world matured to perfection outlasts that of a world forming up, then regardless of all the damage wreaked constantly by transience, the Universe's circumference will nonetheless and on the whole expand. (1:319.19-1:320.2)[12]

---

[12] Kant, *Werke* (Academy Edition), 1:319.19-1:320.2: 'Es scheint, daß dieses den Welten, so wie allen Naturdingen verhängte Ende einem gewissen Gesetze unterworfen sei, dessen Erwägung der Theorie einen neuen Zug der Anständigkeit giebt. Nach demselben hebt es bei den Weltkörpern an, die sich dem Mittelpunkte des Weltalls am nächsten befinden, so wie die Erzeugung und Bildung neben diesem Centro zuerst angefangen: von da breitet sich das Verderben und die Zerstörung nach und nach in die weiteren Entfernungen aus, um alle Welt, welche ihre Periode zurück gelegt hat, durch einen allmählichen Verfall der Bewegungen zuletzt in einem einzigen Chaos zu begraben. Andererseits ist die Natur auf der entgegengesetzten Grenze der ausgebildeten Welt unablässig beschäftigt, aus dem rohen Zeuge der zerstreueten Elemente Welten zu bilden, und indem sie an der einen Seite neben dem Mittelpunkte veraltet, so ist sie auf der andern jung und an neuen Zeugungen fruchtbar. Die ausgebildete Welt befindet sich diesemnach zwischen den Ruinen der zerstörten und zwischen dem Chaos der ungebildeten Natur mitten inne beschränkt, und wenn man, wie es wahrscheinlich ist, sich vorstellt, daß eine schon zur Vollkommenheit gediehene Welt eine längere Zeit dauren könne, als sie

4. ULTIMATE NATURAL PATTERN: THE BIG BOUNCE

Kant stares into the abyss, and the abyss stares back. Such a reflected stare can easily turn monstrous. And still he marvels, with a smile.[13] What he is doing in *Universal History of Nature* is to map out the history of histories. Nature's history is universal in space; it concerns everything that coexists. It is also universal in time, concerning everything that ever was and ever will be. Kant looks for structure and finds it. He claims to see the ultimate natural pattern. Is this madness? Conventional philosophers, whose trade is to shrink Big Questions down to harmless nuggets, would of course nod, emphatically. But they would be wrong. Kant's gaze is clear-sighted. His speculation in *Universal History of Nature* is coherent and systematic. His contentions agree with the facts as we know them and have emerged as anticipations of what we are meeting now at the boundaries of knowledge. The Phoenix of Nature, swinging to entropy and back, has returned to academic discourse as the Big Bounce.

Since the Big Bounce is not yet as familiar as the Big Bang, one might as well start with the latter, 13.7 billion years ago, when nature flared outward from a prone singularity. The Big Bang is at the heart of the research consensus known as the Standard Model. The Big Bang is the rational inference from the red-shift of galaxies far

---

bedurft hat, gebildet zu werden: so wird ungeachtet aller der Verheerungen, die die Vergänglichkeit unaufhörlich anrichtet, der Umfang des *Universi* dennoch überhaupt zunehmen.'

[13] F. Nietzsche, *Jenseits von Gut und Böse*, § 146, *Werke*, 5:98: 'Wer mit Ungeheuern kämpft, mag zusehn, dass er nicht dabei zum Ungeheuer wird. Und wenn du lange in einen Abgrund blickst, blickt der Abgrund auch in dich hinein.' ('He who fights with monsters should look to it that he himself does not become a monster. And when you gaze long into an abyss the abyss also gazes at you.' F. Nietzsche, *Beyond Good and Evil*, trans. R.J. Hollingdale (London: Penguin, 1990).

outside the Milky Way, a red-shift first measured nearly a century ago. Distant light reaches us in elongated wavelengths without exception. Chased through a prism, such light unfurls into lopsided rainbows: skinny in the blue, fat in the red. The one explanation that has held up (and hardened through other confirmed predictions) is that light red-shifts as its sources recede from us and each other. Like dough rising, nature expands outward. Like raisins in the dough, nebulae pull away from one another. Like a coil being stretched, wavelengths of their reddening light lengthen to an observer. So much is clear: a chorus of data tells us that nature expands like a wavefront of a primordial, bygone bang.

A recent addition to the Standard Model is the Big Rip. It is the rational inference from the acceleration of cosmic expansion measured a decade ago.[14] Galaxies are pulling away from one another, and from us, faster than they used to. The travelling wavefront is gaining velocity. Nature's expansion is speeding up. Yet any given acceleration, of any frame within another, eventually hits the tolerance limit of the framework of acceleration. When the limit is hit, the dynamic geometry will reorder itself, which is a polite way of saying that things will fly apart.[15]

Big Rip points to Big Crunch.[16] When things rip, the fabric that holds them will tatter and unravel. While one tends to think of a dimensional fabric as what holds things together, it may be more exact to think of it as what holds them apart. Untethered from their place, nothing will hold the displaced at bay. Ripped, the fabric and its places will buckle, crumple, and fold. It'll crunch.

The Big Crunch would stop at a singularity. This is the Universe squeezed together as tight as it gets; parameters shoot off to infinity or nearly so. It is the null point. It is a prone state harbouring the Big Bang and contains all the conditions for yet another cosmic inflation. So the cycle starts all over again. Ergo the Big Bounce.[17] As Big Bounce, the Phoenix returns and suggests the ultimate natural pattern.

5. PERSPECTIVAL CONVERGENCE ON ABSOLUTES

Conventional philosophers are so in love with questions that they are at a loss what to make of answers. Thus scholarly lacunae perpetuate themselves, and inconvenient truths such as the Kantian cosmogony are best ignored. But one can play the scepticist game only for so long. In the end, information prevails. Remember how the *Critique* ends: anybody, so Kant says, can do research any way they like. But research that leads somewhere is not only systematic but also on a track that is equidistant from two extremes: the Hume extreme, denying everything, and the Wolff extreme, affirming everything. By themselves, doubt and dogma are sterile. It's only what's in between that is fertile. Between them unfolds the critical path. If we follow it, odds are that we'll answer the Big Questions that have troubled reason for so long.[18] Thus the critical path leads to ultimate patterns. While absolutes are nowadays outside the philosopher's comfort zone, they are the bread and butter of cosmology. Absolutes are the limits of reality, edges so extreme that they are invariably the same. The Phoenix wave of the cosmos, the Big Bounce, is such an absolute, and so are its geometro-dynamic parts: the trough that is the Big Bang; the peak that triggers the Big Rip; the fall-to-trough that is the Big Crunch; and the rise-to-peak that follows the Big Bang.

The Big Bounce makes news because it is the convergent outcome of two distinct research programs. Theoretical physics involves two major rival approaches to the ultimate limit. One is string theory, and another is loop quantum gravity theory. String theoreticians have insisted on the possibility of a Big Bounce for years already.[19] This insistence didn't raise many eyebrows since string theory is full of strange claims. But in 2008, researchers who work for the competition, loop quantum cosmology, and who proceed from quite different assumptions, have arrived at just the same conclusion once more.[20]

---

[18] *Critique of Pure Reason*, conclusion, A 856/B 886; in *Werke*, 3:552. Compare Kemp Smith's translation: 'As regards those who adopt a *scientific* method, they have the choice of proceeding either *dogmatically* or *skeptically*; but in any case they are under obligation to proceed *systematically*. I may cite the celebrated Wolff as a representative of the former mode of procedure, and David Hume as a representative of the latter, and may then, conformably with my present purpose, leave all others unnamed. The *critical* path alone is still open. If the reader has had the courtesy and patience to accompany me along this path, he may now judge for himself whether, if he cares to lend his aid in making this path into a high-road, it may not be possible to achieve before the end of the present century what many centuries have not been able to accomplish; namely to secure for human reason complete satisfaction in regard to that with which it has all along so eagerly occupied itself, though hitherto in vain.' See Kant, *Critique of Pure Reason* (New York: St Martin's press, 1965), 668-9.

Inquiries that are on to something exhibit certain traits. One sign is that investigators find themselves suddenly very busy. Activity teems, publications abound, and bibliographies grow longer and longer. Another sign is that inquiries that come from different theoretical locations, use different tools, and approach a question from different angles suddenly find themselves converging on the same answer. When inquiries draw close to an absolute, a relative convergence fuses the perspectives into one view.

So it appears the cosmos is indeed how Kant describes it: *a place in between* and bounded by limits on either side (1:319.32-33). Looking backwards, we see the Big Bang as a bottleneck from a past universe. Looking forwards, we see cosmic acceleration as the first harbinger of future ruin and another Big Bang.

Thus philosophers who wish to break with the conventionality of their field can no longer afford to ignore

[20] The cover title of the October 2008 issue of *Scientific American* has the headline: 'Forget the Big Bang: Now it's the Big Bounce – quantum gravity theory predicts the universe will never die.' See also M Bojowald, 'Follow the bouncing universe,' *Scientific American* 299.4, 2008: 44-51; cf. online version 'Big Bang or Big Bounce?' and M Bojowald, 'Loop quantum cosmology,' *Living Reviews in Relativity* 11.4, July 2008, lrr-2008-4.

Kant's second, burned book, and its core idea, the Phoenix of Nature. For a decade now, string theorists have pointed out the genius of the early Kant, and a handbook on cosmology issued in 1998 from these quarters characterises the cosmogony of *Universal History* as 'the essence of modern models'.[21] After the corroboration from loop quantum gravity, sceptical loopholes would seem to have closed. Now we may wonder what this conceptual triumph means. Determining this, I suspect, defines philosophy's task in this century. Let the scientists figure out the answers to the Great Questions, and let the philosophers add the answers up, rationally, synthetically, and thereby fill the void of monotheistic bankruptcy by crafting a new world wisdom.

On Creation in the Total Extent of its Infinity in Both Space and Time[1]

Immanuel Kant
Translated by Martin Schönfeld

The Universe, with its immeasurable greatness, endless (1.306) diversity, and beauty, which shines up at all angles, puts us in a state of silent wonder. And whenever the idea of all this perfection fires up the power of imagination, the understanding falls into a state of delight, as soon as one considers how so much splendour and grandeur flows from a single universal rule, in eternal and right tact. The Sun, with its powerful attraction at the centre of all orbital rings, forces the inhabited planets of its system to cruise eternal rounds. The planetary world system, as we have seen, is completely made up of the basic stuff of all world-matter. Originally, this matter was spread out. The fixed stars, which the eye finds in the hollow deep of the sky – an abundance that seems to suggest a kind of wastefulness – are all suns and system-centres similar to our own.

---

[1] Chapter Seven of Kant's *Allgemeine Naturgeschichte und Theorie Des Himmels oder Versuch von der Verfassung und dem mechanischen Ursprunge des ganzen Weltgebäudes, nach Newtonischen Grundsätzen abgehandelt* [*Universal History of Nature and Theory of the Heavens or An Essay on the Constitution and the Mechanical Origin of the Entire Structure of the Universe Based on Newtonian Principles*] (1755). Page numbers in the margin refer to the Akademie edition of Kant's Work

The method of analogy suggests that these far-flung systems were formed in the same way as the one in which we live. The method of analogy further suggests that these systems, too, evolved from the smallest particles of basic matter. These particles used to fill the infinite sweep of Divine Presence, which we call empty space.[2]

1.307) If it appears now that all worlds and world-structures share a pattern of emergence; that among the elements the force of attraction is unlimited and universal, and the force of repulsion is just as efficacious and general; and that at infinity the large and the small are both small – if this is all true, should then not all world-structures organize as one network and systematically interact as well? A systematic interplay, to wit, that would be equal to that of the celestial bodies in our solar neighborhood? And if this is so, would the world-structures then not have to link up just like Saturn, Jupiter, and Earth do, all of which are systems of their own, and yet connect into even larger system?[3]

---

2. The 'infinite sweep of Divine Presence' (*diesen unendlichen Umfang der göttlichen Gegenwart*) raises a question as to how to read the text. Kant often uses words such as 'God,' 'Divine,' and 'revelation' (*Gott*, *göttlich*, *Offenbarung*), making the text sound like an exercise in rational theology. Yet the actual claims made by Kant suggest that such a conventional reading is misleading. Here, God and Nature merge; Nature is creative; and 'God' appears to denote a kind of 'universal world spirit' or 'Proteus of Nature'; see also the 1754 essay *Aging Earth* (2:211.29 and 2:212.15). While Kant hesitates to come out as a pagan ('free-thinker') or pantheist ('Spinozist'), we should note that such views were not tolerated in Germany until the Jacobi-Mendelssohn controversy in 1783. *Universal History of Nature* was written in the context of censorship. In 1725, Christian Gabriel Fischer (1686-1751), professor of natural philosophy, espoused pagan-pantheist perspectives; he was fired from the Albertina, banned from Königsberg, and exiled from Prussia.

3. Earlier in the book (Part I), Kant considers the Milky Way and other galaxies. He reasons that an analogy obtains between the evolution and structure of the Milky Way and other galaxies. He infers that the Milky Way is a star cluster rotating around a central axis; centrifugal forces flatten the poles, make the equator bulge, and compress the cluster into a disk (1:249-252). William Herschel confirmed Kant's conception in 1811. In 1750, five years before Kant published *Universal*

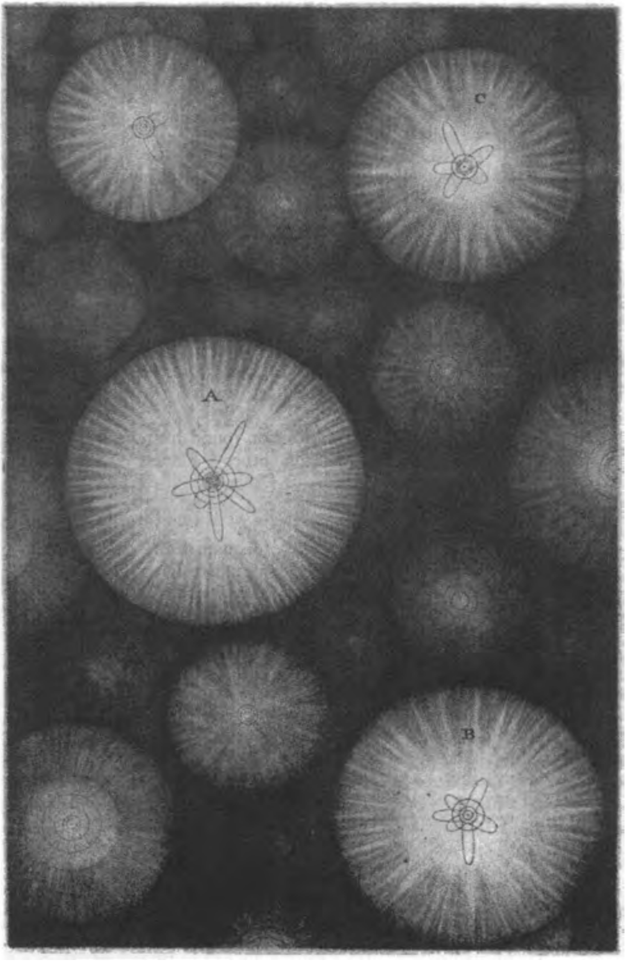

Plate XVII in Thomas Wright's *An Original Theory or New Hypothesis of the Universe* (1750): 'A kind of perspective View of the visible creation, wherein A represents the Sun, B, that supposed round Syrius, and C, the region about Rigel. The rest is a promiscuous Disposition of all the Variety of other Systems within our finite Vision, as they are supposed to be posited behind one another, in the infinite Space, and round every visible Star. That round every Star then we may justly conjecture a similar system of Bodies, governed by the same Laws and Principles with this our solar one, though to us at the Earth for very good Reasons invisible.'

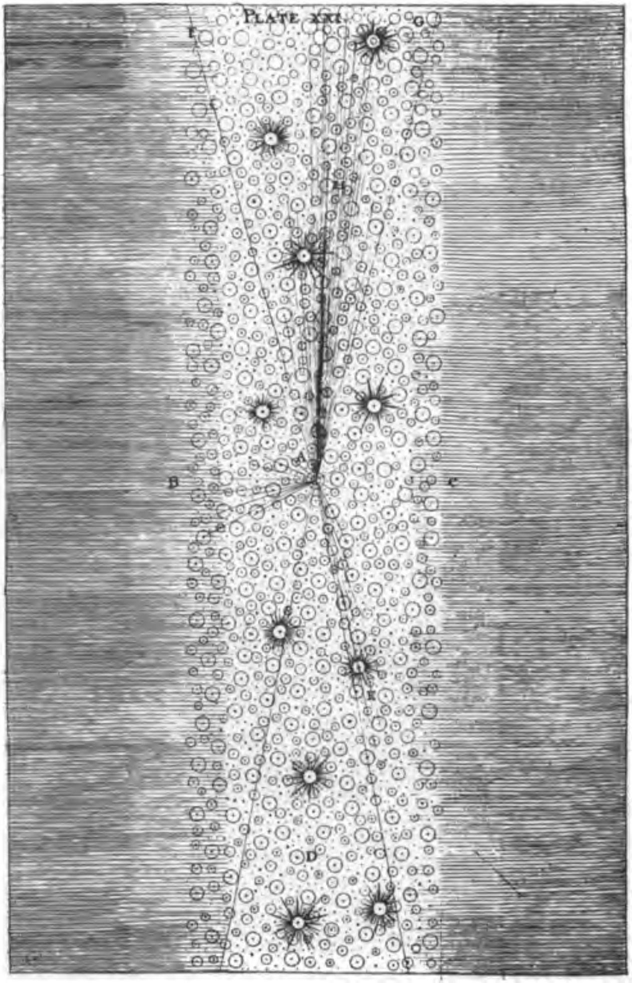

Plate XXIII in Wright (1750): The phenomena of the Milky Way – 'a vast infinite gulph, or Medium, every Way extended like a plane, and inclosed between two Surfaces [...] all the Stars scatttered promiscuously [...] as to fill up the whole Medium with a kind of regular Irregularity of Objects.'

Suppose you take a given point within the boundless space in which all the suns of the Milky Way formed. Suppose further that at that very point Nature's evolution from chaos arose by an unknown cause. Then the greatest concentration of mass will have accreted there. So a body of huge attractive force will have condensed. This will have given the galactic centre-point the power to draw all other emergent star systems into a vast enveloping sphere, and to make them sink toward itself as their gravity-well. Thereby the point will have forged a system around itself, analogous to the system created by the Sun in its own small sphere, and made from the same elementary basic matter that had moulded the planets. Observation makes this conjecture virtually certain. The star cluster emerges as a system because it serves as a frame of reference for a collectively shared plan, just as the planets, clustering around the Sun, are the frame of our solar system. The Milky Way is the zodiac, as it were, of these higher world-structures. These structures hardly deviate from the zodiac-zone; their light always illuminates the ribbon of the Milky Way. Similarly, the planetary zodiac glints in discrete spots through the sunshine illuminating these spheres, even though these spheres are just a few sparse points. In the higher world-structure, each sun creates with orbiting planets a system of its own. That suns everywhere form systems, is a circumstance that does not prevent such suns from being elements of an even larger system – just like the fact that Jupiter or Saturn serve as centres to their lunar companions does not prevent such planets from being integrated into the tight

---

History, Thomas Wright suggested the idea of a disk-like Milky Way, but, as various commentators have pointed out, the credit should go to Kant: Wright only states the notion while Kant explains it.

organization of a larger system. Is it not possible to see in this precise agreement of organization – Milky Way here, solar system there – the same cause, and the same type of causation?

So: if the stars are organized as a system whose circumference is informed by the gravitational sphere of its central mass, then will it not be likely that even more star systems
1.308)– more Milky Ways, as it were – evolved in the boundless field of space? Earlier we were amazed to see celestial figures arise as such star systems – such Milky Ways, if I may express myself thus – that cohere by a communally shared design.[4] Such star systems show themselves in elliptic guises, because they are angled at various degrees against the eye. Infinite distances from the eye weaken their light to a gleam. Their diameter is, so to speak, infinities and infinities larger than that of our solar system. And yet, these star systems have surely evolved in the same way and unfolded from the same causes; furthermore, the

---

[4] The idea that the fuzzy blobs faintly visible on a dark and clear night could be star clusters originated with Thomas Wright, who called them 'knots of stars'. Kant read a review of Wright's *Original Theory and Hypothesis of the Universe* (1750) in *Freie Urteile und Nachrichten zum Aufnehmen der Wissenschaften und Historie überhaupt* (1751). Just as Kant extrapolates from our solar system to the Milky Way, so he extrapolates from the latter to other galaxies. Calling them 'foggy stars' (*neblichte Sterne*, 1:254-1:255), he argues they are not just knots, but rather *systems* of stars. In 1761, Johann Lambert suggested a similar view in *Cosmologische Briefe*. In the 1780s, Charles Messier prepared a catalogue listing 103 nebulae. In 1802, William Herschel published a catalogue of 2,500 nebulae; in the 1830s, his son, John Herschel, added 1,300 more. In 1864, William Huggins discovered through spectrographic analysis that nebulae differ from stars and speculated they are of some luminous fluid. At the end of the nineteenth century, most astronomers assumed nebulae were proto-stars *inside* the Milky Way. Kant's idea, that they are Milky Ways in their own right, was marginalised. In the 1920s, Heber Curtis revived Kant's idea, calling such nebulae 'island universes'. In 1924, Edwin Hubble examined M 31 (the Andromeda nebula), determined its location to be outside the Milky Way, and verified Kant's idea. See M. Schönfeld, *Philosophy of the Young Kant* (Oxford: Oxford University Press, 2000), 116 and 272.

Nebula NGC346 (Credit: NASA,ESA,Hubble Heritage Team [STScI/AURA]).

same dynamic engine that had structured them continually maintains them.

Now, if we see these star systems, in turn, as links in the great chain of Nature as a whole, then we will have just as much reason as before to think of these links as being concatenated in reciprocal networks.[5] By the law of primordial evolution that governs all Nature, we should think of these connections as already weaving another system. That even greater system would be ruled by the gravitational pull of a central body inside its regular frame, with an even larger attractive force than all the others considered thus far.[6] The force of attraction is the cause of the systematic organization among the stars of the Milky Way. This force is active even in the distances of these world structures. In fact, its power is such that it would actually knock them out of their systematic places and bury the world in inexorably looming chaos, if it were not for the steady radiation of centrifugal forces serving as counterweights. In their interplay, attractive and centrifugal forces yield the relation that grounds systematic organization. Attraction connects substances through mutual dependencies. Now, surely, this force must be a property of matter, and it must reach as far as co-presence, which is a property of space. Speaking more precisely, attraction must be the very relation that unites the parts of Nature in one space. Hence attraction stretches through the whole sweep of space towards the depth of infinity. Light reaches us from these distant systems, but

---

[5] 'Star systems' (*Sternensystemata*), here, are galactic systems; see Kant's previous paragraph.

[6] This is the first conjecture in history about the possibility of a Local Group in the Virgo Cluster.

I

Plate XXXII in Wright (1750): A sectional view of 'the endless Immensity [...] an unlimited Plenum of creations not unlike the known Universe'.

light is merely an impressed motion. Should then not attraction reach that far, too? Attraction is the primordial source of motion; it is more ancient than motion, and it 1.309) does not need external causes. Also, attraction cannot be stopped by any obstacle, since it acts without resistance in the inner reaches of matter, even when Nature is fully at rest. Considering this, I ask: Will attraction not have set star systems in motion as well? And will attraction then not be the cause of all the systematic connection and the permanence of Nature's links, which protects them from dissolution here, just as in the smaller frames?

But then, what is going to be the ultimate end of these systematic arrangements? Where will creation ever stop? Note that creation, since it is proportional to the might of Infinite Being, cannot have boundaries at all. Enclosing the realm of revelation within a sphere of the radius of the Milky Way does not bring us one step closer to the infinity of God's creative power than putting this realm into a ball the size of an inch. All that is finite, involves limits, and can be measured, is equally far away from infinity. Is it not incoherent to conceive of a divinity as acting with an infinite small part of its creative potential? Or to take the infinite power of divinity as a force inert and sealed up, forever wanting for some way of showing itself adequately? This power, after all, is the cornucopia of the true boundlessness of natures and worlds. So, is it not far more decent – or, to say it again, with more precision: is it not *necessary* – to take creation as it would have to be such as to testify to that very

---

7. Kant's first question appears to refer to the Christian concept of a coming eternal afterlife (*künftige Folge der Ewigkeit* 1:309.34). The infinity of 'varieties and change' (*von Mannigfaltigkeiten und Veränderungen* 1:309.35) comes into play in that an eternal afterlife counts as real eternity only if it is an actually infinite time span. The essence

power that cannot be measured by any yardstick? Thus the cosmic field of the revelation of the Divine traits must possess the infinity of these traits themselves.

Eternity would not be big enough to contain the traits (1.310) of a Supreme Being unless infinity is also expressed as a spatial field. Complexity, form, beauty, and perfection are certainly relations of elementary fields and substances that constitute the stuff of the cosmic system. This is evident in the eternal designs crafted by Divine Wisdom. It is also appropriate to this wisdom that such designs unfold by implanted universal laws along unconstrained courses. So, with sound reason, we can say that organisation and design of the world will occur along a time flow, step by step, as the

---

* [*Kant's footnote*] The concept of the world's infinite extension has opponents among the experts of metaphysics; a recent example is *Magister* Weitenkampf. Now since these gentlemen cannot grant this idea because of the alleged incoherence of the notion of a set without numerical limits, I just want to ask this: When eternal afterlife comes, will not its future flow contain a genuine infinity of varieties and change?[7] And is not this infinite set fully present once and for all in the Divine Understanding? (1:310) Now, if it were possible that God realised in a successive series the notion of infinity that presents itself to His understanding, why should not the same concept be able to denote another infinity, in a *connected network* that is spatial? And if this were so, would it not thereby make the circumference of the world without borders? While one seeks for an answer to this question, let me use this opportunity to solve a problem related to an explanation of the nature of numbers; a question deserving of clarification. A power guided by supreme wisdom reveals itself in creation: does the set of actually created revelations constitute a fraction compared to the set of what this power *could* have created?

---

of time is flow, visible in varieties and change. Without change there is no time; and without time, there is no eternity – if eternity were *outside* time, it would be a stasis and thus nothing. Christians distinguish between creator and creation, conceiving the former as active and infinite, the latter as passive and finite. Echoing the views of Martin Knutzen (1713-51), Johann Weitenkampf (1726-58) argued against a possibly infinite extension of nature. Knutzen, a Christian, held the chair of metaphysics and logic in Königsberg when Kant attended college. As a teacher, Knutzen promoted Weitenkampf and Friedrich Buck (1722-86), but made Kant drop out in 1748 over his *True Estimation of Living Forces* (w. 1744-47, p. 1749). Weitenkampf and Buck were candidates for Knutzen's succession in 1751; Buck gained the chair of metaphysics and logic in 1756.

unfolding of a stock of created Nature-stuff. The sole direct effect crafted by Divine Presence is pure matter, whose properties and powers ground all change. Hence Divine Presence must at one point be so rich and complete that the development of its compositions in the flow of eternity can radiate along a plan that has everything that can be; that does not accept any measure; and that, in short, is infinite.

So: since, now, creation must be spatially infinite, too – or, at least, has been actually infinite over matter already from the start, and is bound to be infinite as regards form via an evolutionary process – then it follows that cosmic space will teem with an infinite number of worlds. Now, earlier we said that systematic connection informs all specific parts. Does this mean that systematic connection will also inform the Whole? Will the Universe, the All of Nature, be structured as a unified system, by the bond of attraction and repulsion? Yes indeed, I say. For imagine 1.311) there were only isolated world systems, without a shared link to a whole, and that these systems made up an actually infinite set. Imagine, further, a precise equilibrium among all the attractive forces of all these disparate parts from all sides; an equilibrium that would protect such a system from the ruin threatened by such mutual inward attraction. Clearly, this scenario requires such a perfectly exact determination of dynamically balanced distances that the tiniest shift would pull the Universe into doom, surrendering it to collapse. While such a pull may take eons, it will inexorably lead to this end. A cosmic organization that does not sustain itself without a miracle lacks the property of permanence that is a trait of Divine choice. To such choice it would be far more appropriate if the whole creation were made into a single system.

PLATE. XXXI.

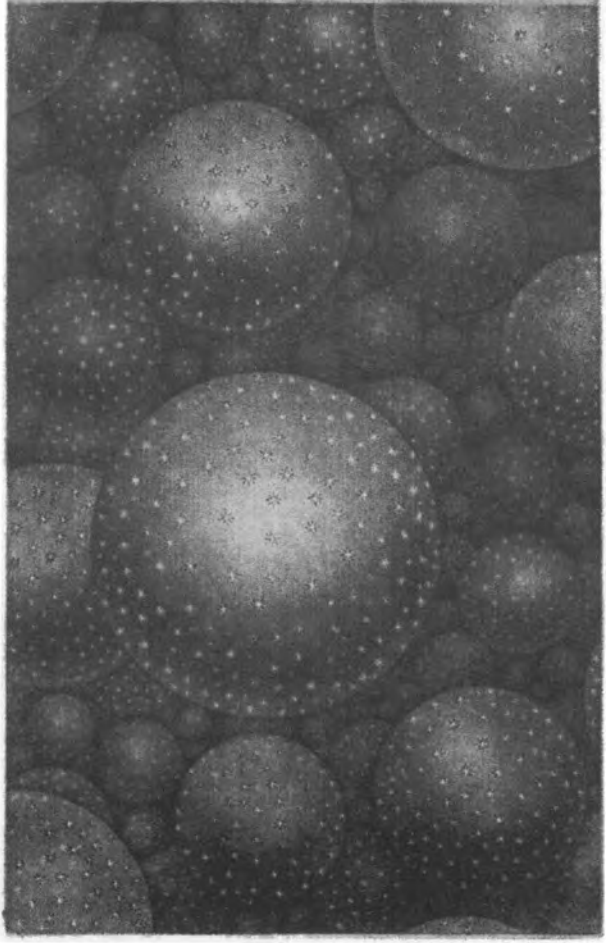

Plate XXXI in Wright (1750): '[A]s the visible creation is supposed to be full of siderial Systems and planetary Worlds, so on, in like similar Manner, the endless Immensity is an unlimited Plenum of creations not unlike the known Universe; a partial view of Immensity, or without much Impropriety perhaps, a finite view of Infinity.'

Galaxy NGC1672 (Credit: NASA,ESA,Hubble Heritage Team [STScI/AURA]-ESA/Hubble)

In this system, all the worlds and world structures that fill up the whole spatial infinity form a network around a common centre. A scattered swarm of world systems would collapse with undiminished momentum into doom and destruction no matter how far apart they were from one another, unless systematic motions create a relational order towards one universal centre. Such a cosmic mid-point would be the attractive centre of the Universe and the column that holds up Nature.

Nature's universal centre and gravity-well is the same in Nature's evolved and raw states. At this centre mass would surely concentrate towards the greatest attraction. Its gravitational field would hold all worlds and structures which have been produced over time and will be produced unto eternity. One can probably assume that Nature started to form around this universal centre and gravity-well. There the systems would also cluster with maximum density. The farther they were placed from the centre, the thinner their dispersion would be, until they lost themselves in the infinity of space. We can identify this rule by analogy with our solar system. Indeed, its makeup serves to illustrate a further dynamic feature: over vast distances the pull of the primary body at the centre fuses with the attractive forces of orbiting sub-systems so that the systematic attraction radiates essentially from one mass against even farther systems. This will help us to comprehend the whole of (1.312 Nature, in the whole infinity of its sweep, as one single system.

Now let us see how Nature's universal system evolves in lawful mechanical ways from a material striving towards complexity. In the infinite spatial dispersion of the elementary, primordial matter, there must be a place with the highest density of basic material. There evolution happens first. This process yields the mass that is the column sustaining the Universe. Granted, infinite space does not really have a centre point. But if one considers a given relationship based on real degrees of primordial mass density, one can arguably speak of a centre-point within infinity – it would simply be the place of peak material density. Outside this centre, density rarefies according to distance. The formation of a mass with maximum attraction defines the centre as the gravity-well into which all other elementary matter will sink, even when such matter is simultaneously weaving its own specific networks. So it will not matter how far the evolution of Nature reaches – this centre of the infinite sphere of creation unifies the entire cosmos into a system.

Now here is something vital that demands applause and deserves full attention. It is this: As a consequence of Nature's organization according to the described system, creation, or rather, Nature's evolution, begins at this centre-point, spreads out step by step in steady progression, towards all farther reaches, and fills infinite space with worlds and subordinate systems along the flow of eternity. Let us savour this vision for a moment with quiet pleasure. I find nothing that elevates the human spirit to nobler reverence than the part of the theory that concerns creation's successive completion. This part opens to the spirit a vista into the boundless field of omnipotence. As soon as one grants that matter, or the stuff of world formation, is not homogenously scattered in the whole spatial infinity of Divine
1.313) Presence, but is instead spread out according to a law, which

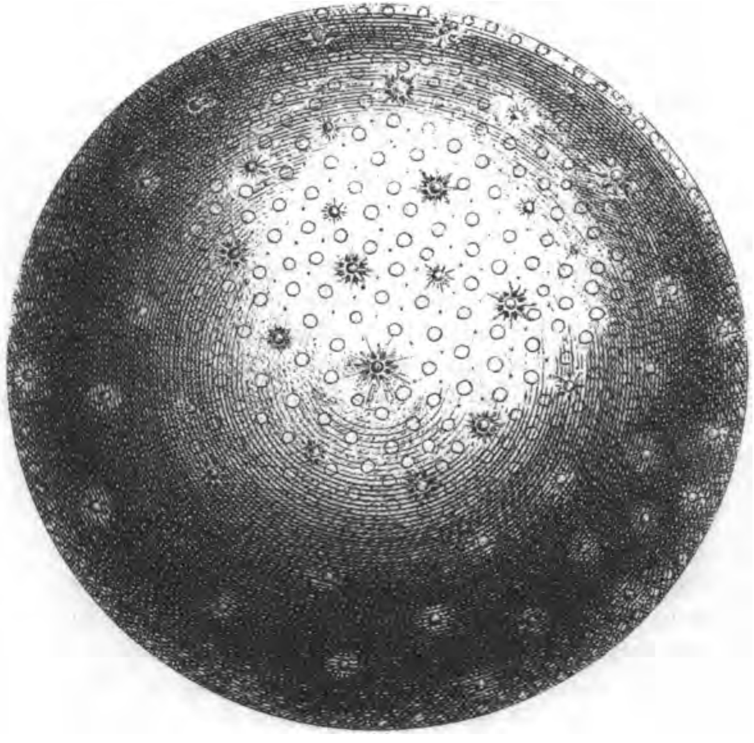

Plate XXIV in Wright (1750): ‘A representation of the convexity, if I may call it so, of the intire creation, as a universal Coalition of all the Stars consphered round one general Center, and as all governed by the same Law.’

is perhaps a law concerning particle density, then Nature's first stirring will have tied the start of evolution to this centre-point. After this start, and as the next evolutionary step, the space beyond the centre shapes worlds and world-orders into a systematic structure around this centre. This happens gradually and over time. The span of a given time is proportional to the size of the work to be completed. In any finite time-period it is possible to structure only a finite sphere around this centre-point. The infinite remainder, meanwhile, will quarrel with confusion and chaos. The farther areas in such infinity are from the sphere of evolved Nature, the further they will be from a state of full evolution. Seen from our perspective in the Universe, it would seem as if we looked at wholly completed creation and, so to speak, at an infinite array of systematically connected world-orders. And yet, from what has been said, it follows that we must be quite close to the centre-point of Nature; at any rate so close that Nature has already evolved from chaos here and attained its appropriate perfection. But if we could step outside this evolved sphere, we would see chaos. The random scattering of elements is inversely proportional to the proximity to the centre-point. The closer the scattering is, the more it will have already partially emerged from the raw state and be on its way toward full evolution. But the farther the scattering is, the more it will lose itself with each outward step into utter dispersion. If we could travel outside this sphere, we would see how the spatial infinity of Divine Presence and its store-house of possible natural forms are buried in a night of silence, a night filled with matter that serves as building material for future generations of worlds. Impulses set this matter into motion.

A faint stirring will be the onset of the very motions that are going to make these boundless desert-spaces come alive. Many millions of years and centuries will perhaps go by before our home-sphere of evolved Nature will expand to thrive in these spaces with that kind of completion that is its feature now. And perhaps a time span of similar length will have to pass before Nature takes such a great step (1.314) into chaos. But how long it will take does not matter, for the sphere of evolved Nature is incessantly busy with its expansion. Creation is not the work of an instant. Creation starts with the production of an infinity of substances and matters. It then continues with producing ever higher levels of fertility throughout eternity. Millions of years, no; whole mountain ranges of millions of centuries will pass, during which always new worlds and world-orders come into existence and reach maturity, one by one, in remote reaches far from Nature's centre. Whatever systematic organization the parts have with respect to one another, all of them attain a universal relation to the cosmic mid-point that had become the primordial and creative centre through the gravitation of its extraordinary mass. The infinity of future time-flows will make all spaces of God's presence wholly come alive. Step by step, this infinity will turn these spaces into the regularity that is appropriate to the fittingness of Divine design. If we could, with bold imagination, sum up the whole eternity, as it were, in a single notion, then we would also be able to see the whole spatial infinity filled with world-orders and thus see creation complete. But in the flow of eternity futures are always infinite and pasts always limited. So the sphere of evolved Nature can only be an infinitely small part of the essence that carries the

Young stars in the extended arms of the Southern Pinwheel Galaxy M83 (Credit: NASA/JPL-Caltech/VLA/MPIA) seed of future worlds, and that seeks to evolve from chaos over shorter or longer periods. Creation is never done. Creation has a beginning but not an end. creation is constantly in the process of generating new dawns of Nature, new things, and new worlds. The work that it completes is proportional to the time the work takes. Creation needs an eternity to animate the whole boundless reach of infinite spaces with worlds without number and end. One can say of it what the greatest of the German poets writes about it:(1.315)

Infinity! Who can fathom you?
For you worlds are days, and humans are instants;
Perhaps the thousandth sun is now turning,
And a thousand more are still in store.
Like a clock, animated by a weight,
A sun hurries on, moved by divine force:
Its spring winds down, and another strikes,
You, though, stay the same and count them not.
von Haller[8]

It is no small delight to sweep one's power of imagination beyond the boundary of completed creation and outward into the arena of chaos, and to see how Nature is first half-raw, outside the sphere of the unfolded world, and then loses itself into the distance, along all degrees and gradations of imperfection into utter unformed space. Some might say such audacity deserves rebuke. Is it blameworthy to feign a hypothesis and to praise it as a model of rational delight? Is it perhaps all too arbitrary to contend that Nature is created only in its infinitely small part; that infinite spaces are still fighting with chaos; and that in the far future these spaces will contain entire armies of worlds and world-orders, in all their order and beauty? I am not so committed to the consequences of my theory, that I would not see how this speculation – a successive expansion of creation through infinite spaces filled with creative material – is vulnerable to the reproach of indemonstrability. Granted, this map of infinity contains a model that seems destined to be hidden forever from human understanding. And yet, I expect from those readers who know how to estimate degrees of probability, that they do not reject out of hand and as sheer lunacy such a map. I expect this, especially if one considers the method of analogy. For analogies must always and everywhere guide us as soon as the understanding lacks the thread of incontrovertible proof.

---

[8] Albrecht von Haller (1708-1777), *Unvollkommene Ode über die Ewigkeit* (1743; alternative title *Unvollkommnes Gedicht über die Ewigkeit*), stanza 4; cf. 1:315. Compare also the nice translation by Ian Johnston at http://records.viu.ca/~johnstoi/kant/kant2e.htm

Now, one can support the analogy through acceptable reasons as well, and the reader, whose approval I hope to gain, may perhaps add even more important ideas. We need to keep in mind that creation has the trait of I.316) permanence only through a balance between the universal striving of attraction permeating all parts of nature, and an equally universal counter-striving. With centrifugal forces, this counter-striving sufficiently repels the inclination of attraction towards collapse and chaos. Together these strivings constitute Nature's universal systematic order. This compels us to assume a cosmic centre that holds all parts of the Universe in a relation of connectivity, and it is this that turns Nature into a system. Add to this the notion of the evolution of astrophysical bodies from dispersed elementary matter, as was explicated in the previous chapters. Since we do not tie this notion to any specific system here but instead apply it to Nature at large, we assume a primordial chaos of elementary matter dispersed in space. Such chaos, in natural fashion, must generate a centre of the entire creation. The whole of Nature is a sphere of active mass that coheres in this centre. In this way, a universal relation obtains that integrates all worlds into a single framework. But in infinite space it is hardly possible to conceive of a type of scattering of primordial matter that leads to a true centre point and gravity-well of Nature as a whole, unless Nature enacts lawfully, increasing entropy from this point outward toward its farthest reaches. Such a law will also posit a difference in time needed by a system in the various regions of infinite space to bring its unfolding to fruition and maturity. This interval would be the shorter the closer the area of an evolving world-order is to the creative centre. At the centre it takes less time to create the systematic unfolding than in the distance, for material elements are more densely concentrated in the former. Since they are more thinly dispersed in the distance, they will accrete later into organization.[9]

---

[9] Kant's idea is that things closest to the stellar or galactic centre would form first and those farthest away, last. This is an aspect of his famous Nebular Hypothesis, verified by G. Kuiper and K. v. Weizsäcker in 1949. According to this hypothesis, put forward elsewhere in *Universal History*, a condensing cloud ripples with tides and forms a gravity-well to concentrate matter until it lights up. The flow of matter to this well – the future Sun – deflects laterally through internal collisions. The laterally-deflected matter revolves around the proto-Sun. The revolving matter coheres into orbital bands. Thus the solar system grows from a cloud. Orbital bands become lumpy; bigger lumps absorb smaller ones; the matter clusters condense into planets. Planets form sooner the closer they are to the centre. The farther one travels from the Sun, the deeper one looks into its past: beyond Neptune wait the old lumpy orbital bands – the Kuiper Belt. Even farther out, beyond the orbital bands, one arrives at the oldest shrouds of the rippling cloud – the Ort Cloud.

ebula NGC346 (Credit: NASA,ESA,Hubble Heritage Team(STScI/AURA)

If one considers now the whole hypothesis developed here, and considers it in its full scope, over both what I have said, and what I shall still lay out, one will not think that the boldness of its implications is inexcusable. 1.317) Every world-order that matures to perfection has a growing and inexorable tendency toward its own doom. This may be counted among the reasons that warrant that the Universe is more fertile in the production of worlds in other areas, to compensate for its deterioration elsewhere. The full range of known Nature may be as small as an atom compared to what is hidden from view above or below our sights, but it still confirms this fertility of Nature. This fertility is boundless, for it is the exertion of Divine Power itself. Countless animals and plants are daily destroyed and fall prey to transience. And yet, no less are created by unexhausted fertile powers of Nature elsewhere to repopulate the emptiness. Large stretches of inhabited land emerge from the seas in an auspicious epoch and are again buried by them, but elsewhere Nature fills the gaps, makes other lands from the watery depths, and blankets the new lands with more fertile riches. In the same way, worlds and world-orders fall apart and are swallowed up by abyssal eternities, and yet creation is constantly busy crafting new evolutions in other celestial regions, compensating loss with gain.

One should not be surprised to see that God's works are transient even on their largest scale. Everything finite, everything with a beginning and an end, contains the mark of limited nature – it has to perish; it has to end. The span of a world-order is so long-lasting in virtue of the magnificence of its designs that it approaches eternity when seen from our perspective. Perhaps thousands, perhaps millions of centuries go by without the destruction of world-orders. And yet a vanity within all finite natures is constantly busy at work to destroy them. Eternity may have all sorts of eons, but in the end all eons lead through steady decline at last to the moment of downfall. *Newton*, that great admirer of God's traits in the perfection of His works, connected deep insight into Nature's grandeur with great reverence for the revelation of Divine Omnipotence. In virtue of the natural trend of the mechanics of motions towards decline, he (1.318) found it necessary to announce in advance Nature's decay. If, as a central consequence of frailty, a systematic organization gets over eons of time even the tiniest conceivable step closer to the state of dissolution, then there must come a moment in the infinite run of eternity when gradual loss will have exhausted all motion.

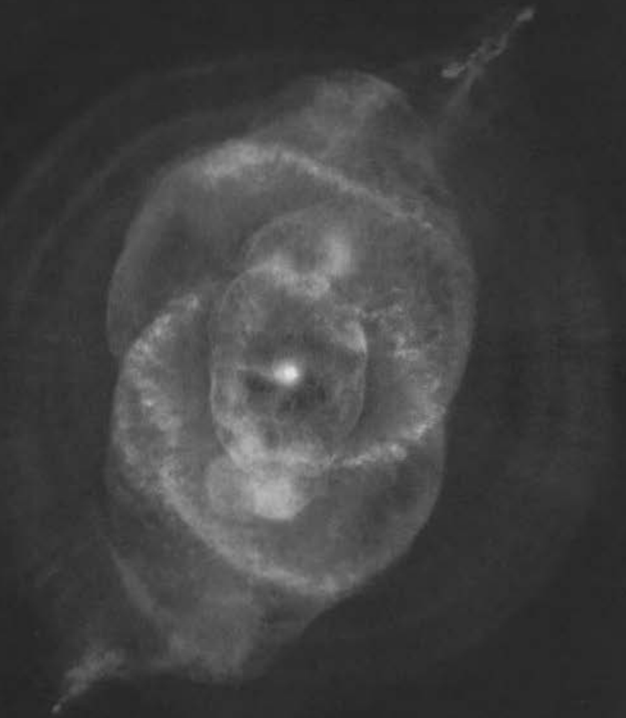
We must not regret the downfall of a world system as a true loss for Nature. Nature demonstrates its wealth in a kind of wastefulness. While some of its parts pay tribute to transience, Nature maintains its entire scope of perfection through countless new creations. How many flowers and insects are destroyed by a single cold day! But even though they are magnificent works of art and proofs of Divine Omnipotence, how little are they missed! Abundance replaces this loss elsewhere. Humans, the apparent masterpiece of creation, are not exempt from this law either. Nature shows itself just as rich, just as unexhausted in creating the greatest of creatures as in creating the least of them. Nature shows that even their doom is a necessary shadow in the abundance of her suns, since their creation costs her nothing. Destructive consequences of contagion, earthquakes, and floods wipe whole nations off the map, but it never seems that this is to Nature's detriment. In the same way, whole worlds and systems leave the stage after having played their role. The infinity of creation is so large that a world or a Milky Way of worlds appears by comparison just as small a flower or an insect compared to the Earth. And while Nature decorates eternity with its mutable creations, God keeps busy forming the the basic stuff that develops into even grander worlds.

> Who sees with equal eye, as God of all,
> A hero perish, or a sparrow fall,
> Atoms or systems into ruin hurl'd,
> And now a bubble burst, and now a world
> Alexander Pope[10]

1.319) So let our sight get used to these terrifying upheavals. They are the common paths of providence. Let us see them with a kind eye. And indeed, nothing fits better than this sight to the wealth of Nature. For if a system of worlds, in the long course of its duration, exhausts all the diversity that its organization can contain, and becomes a redundant link in the chain of beings, then nothing will be more appropriate than for it to play the final role in the drama of the unfolding transformations of the Universe. Paying its dues to mortality is the final role of any finite thing. As we have suggested, Nature shows already in the small parts of its whole notion the very rule of its way that eternal Fate prescribes to everything. And I say it again: Size is no obstacle to doom. For everything that is large becomes

---

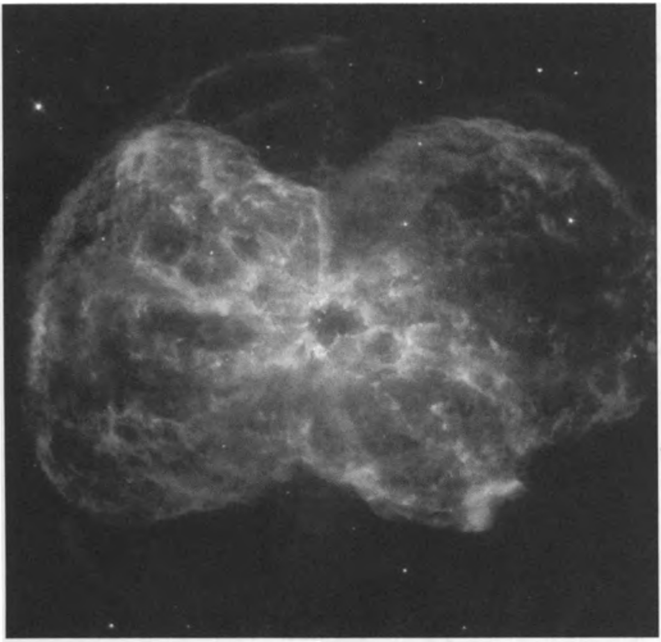
[10] Alexander Pope (1688-1744), *Essay on Man* (1733-34), Epistle 1, lines 87-90. Kant cites a very literal translation by B. H. Brocke (1740); cf. 1:318



Composite image of NGC 6543 or Cat's Eye Nebula. (Credit: [X-ray] NASA/CXC/SAO; [Optical] NASA/STScI).

small, and becomes, as it were, a point if compared to the infinity that creation represents in unlimited space and in the flow of eternity.

It appears that the end, fated to worlds as to all matters natural, is subject to some law. Recognizing this law will lend the theory a new touch, a touch of rightness. By this law, the end touches those worlds closest to the cosmic centre first, just as conception and organization had first started right next to this centre. From there, doom and destruction gradually radiate outward into ever farther reaches from



Solar Nebula (credit NASA,ESA, K.Noll[STScl]).

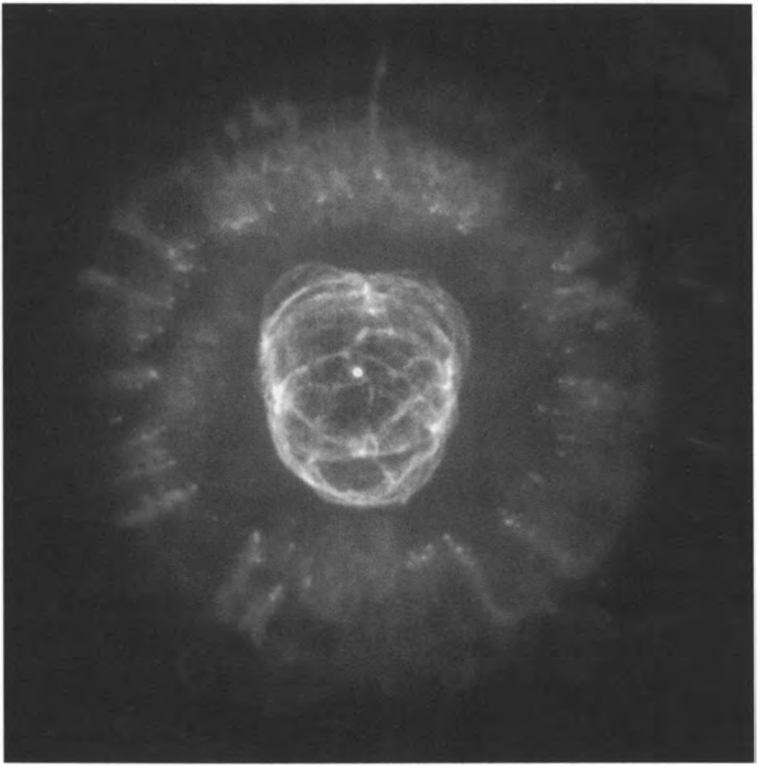
the centre. By general dissipation of motion, the whole Universe, having completed its period, will eventually be buried in uniform chaos. And yet, at the opposite limit of the evolved sphere, Nature is steadily busy spawning worlds from the raw stuff of scattered elements. That is to say, at the one limit Nature rots at the centre, and at the other limit Nature is young and fertile in new creations. Thus the unfolded world is placed in between, constrained by either boundary: The ruins of nature already destroyed; and the chaos of nature yet unformed. And if we imagine, as would be likely, that the length of time of a thriving mature world outlasts that of a young world forming, then regardless of all the damage done by transience, the Universe's circumference will nonetheless and on the whole expand. (1.320)

Now if we want to leave room, finally, for an idea that is just as plausible as it is appropriate to Divine works, then the satisfaction given by such an account of Nature's mutations will soar to the highest degree of delight. Nature is capable of hoisting itself out of chaos into regular order and elegant systematicity. Yet a diminution of motions sinks Nature into new chaos. Is it impossible to believe that Nature might be equally capable of reconstituting itself just as easily from this new chaos as from the old, and of renewing its former structure? The standstill of the machine brought the springs to rest that impelled the stuff of dissipated matter towards motion and order. But could these springs not be wound up once more by the rarefied field of forces? And could they not once again be curbed by the very same general rules toward harmony, whereby original evolution had come about? One won't have to tarry long with misgivings, as soon as one considers the following: A terminal weakening of orbital motions within the world system will make

planets and comets without exception crash into the Sun. The Sun, in turn, will absorb an immeasurable energy increase through the admixture of so many big lumps. This energy increase will be especially great since distant spheres of the solar system consist of the lightest and most combustible materials of nature, by the theory previously laid out. Through new nourishment and the most volatile matter, the fire will flare up into greatest violence. It will doubtless not only dissolve everything into its smallest elements but also radiate and dissipate them into the very same distant spaces that such matters had occupied before the first evolution of Nature. This radiation and dissipation will happen through a force of expansion proportional to the heat, and with a velocity not weakened by any resistance in the dimensional medium. The near-total dissolution of its matter then dampens the violence of the central conflagration. By next linking attractive and repulsive forces, the old productions and systematically related motions will be repeated with no lessening of regularity. In this way Nature will organize a new world system.[11] When a particular
1.321) planetary system decays in this way; when it reorganizes itself by essential forces out of such disorder; when it even repeats this process more than once – eventually an era is bound to come, when even the great system of stars will decay in its motions and sink into chaos. There is little doubt that the concentration of such a boundless lot of fiery charges (which these burning suns are) will dissolve in nameless glow, dissipate in the old realm of its evolutionary

---

[11] This may well be the first conjecture in history about generations of stars. According to current knowledge, the first and long extinct generation consisted of blue hydrogen stars; in their nuclear furnace, the heavier elements of the periodic table formed that make up the more recent populations of stars. The younger a star is (such as the Sun), the higher will be its metal content.



Eskimo Nebula (Credit: NASA, Andrew Fruchter and the ERO Team [Sylvia Baggett (STScI), Richard Hook (ST-ECF), Zoltan Levay (STScI)]). A photograph of a dying star. 'Ten thousand years ago this halo of gas and dust was part of the central star. The aging star then expelled its outer layers into space in successive bursts, forming what astronomers call a planetary nebula. All ordinary stars like the Sun will eventually meet a similar fate.' (Carl Sagan, *The Varieties of Scientific Experience*, London and New York: Penguin, 2006, 267.)

sphere, and accordingly supply the materials to new evolutions by the same mechanical laws. In this way the emptiness can come alive again with worlds and systems. The **Phoenix of Nature** burns itself up only to return from its ashes, come back to life, and be young again.[12] If we now follow the Phoenix through all infinity of time and space, and if we see how Nature, even in the aspect of decay and obsolescence, still has the power for new creations; if we see how, at the other edge of creation and in the realm of unformed, raw matter, Nature proceeds with steady steps toward the expansion of the plan of Divine unfolding, and fills all time and all space with its miracles – if we see all this, then the mind, pondering such vistas, will sink into deep wonder. Yet the mind is discontent with this grandiose object whose transience can never appease the soul, and wishes to get to know that very being up close whose understanding and grandeur are the light source shining through the whole nature as from a centre. With what kind of reverence shouldn't the soul regard its own being, considering that it is supposed to survive all these transformations? It can tell itself what the philosopher-poet says about eternity:

---

[12] My emphasis: On the 'Phoenix of Nature' see my own contribution to this volume.

When next a second Nothingness will bury this world,
When from the All nothing will stay but the place,
When still other skies, bright with other stars,
Will have completed their course:
Then you will be as young as now, just as far from death,
And be as eternally future-bound as you are today.
von Haller[13]

O how happy will reason be, when, among the tumults (1.322) of the elements and the ruins of nature, it is set on a steady height that lets it see the wreckage caused by the frailty of things in the world as if it were a current rushing by its feet. A happy blessedness, which reason may not even dare to wish for, is taught by the Revelation as what we can hope for with conviction. When the shackles that bind us to the vanity of creatures fall off in the very instant that is tuned to the transformation of our essence, the immortal ghost, freed from the dependence of finite things, will find the pleasure of true luck-spiritedness in the community with infinite being. Nature as a whole has a universal and harmonious relation to the well-falling of divinity. Nature is capable of filling a rational creature, which finds itself joined to the arch-source of all perfection, with nothing but steadfast contentment. Seen from this central perspective, Nature will display pure safety, pure integrity, on all sides. Its mutable scenes fail to unsettle the happy poise of a ghost once raised to such height. In foretasting this state with sweet hope, a mind which is still embodied, can already train its mouth in singing these songs of praise that once will sound in all eternities.

---

[13] Albrecht v. Haller (1708-1777), 'Unvollkommene Ode über die Ewigkeit' (first printing 1743).

> When, once in time, the frame of the world flees back into its own nothingness
> And the work of your hands does not differentiate by day and night anymore:
> Then my moved character, firmed by you, should try,
> To draw to your throne in honour and respect of all your power
> My mouth, filled with thanks, should through all eternities
> Prepare unending praise to you and your majesty;
> And yet no praise would be perfect – for o Sir! So tall are you,
> That eternity won't suffice to give praise fit to your dignities.
>
> Joseph Addison[14]

---

[14] Joseph Addison (1672-1719), 'Some Pieces of Divine Poetry', stanzas 12 and 13, *Spectator* 453 (9 Aug 1712); Kant cites a rather free translation by Louise v. Gottsched, b. Kulmus ('die Gottschedin', 1713-62). The poem above is a literal re-translation from Gottsched's paraphrase. Compare Addison's original: 'When Nature fails, and day and night / Divide thy works no more, / My ever grateful heart, O Lord, / Thy mercy shall adore. / Through all Eternity to Thee / A joyful song I'll raise; / For, oh! Eternity's too short / To utter all Thy praise.'

Prospects for Post-Copernican Dogmatism: The Antinomies of Transcendental Naturalism

Iain Hamilton Grant

> For it is not because there is thinking that there is being, but rather because there is being that there is thinking.
> Schelling[1]

> [T]he fundamental error of dogmatism [...][is to] search outside the I in order to discover the ultimate ground of all that is in and for the I.
> Fichte[2]

What is the dogmatism against which transcendental philosophy launched its Copernican revolution? Since Kant's invention of the thing-in-itself, we are apt to think dogmatism in terms of an access problem,[3] and therefore to conclude that any philosophy is dogmatic that, through insufficient attention to its own conditioning, denies that there is an access problem. Yet characterising dogmatism as access-positivism does little to define it positively, providing only a formal regression to inhibit speculative or rational egress beyond reflection, as the Fichte citation above makes sun-clear. Nevertheless, the Fichtean egress-prohibition has latterly been posited as a positive criterion of 'philosophically effective' transcendental arguments:

---

[1] F. W. J. Schelling, *Sämmtliche Werke*, ed. K F. A. Schelling, 14 vols (Stuttgart und Augsburg: Cotta, 1856-61), vol. XIII, 161 n., trans. B. Matthews, *The Grounding of Positive Philosophy* (New York: SUNY, 2007), 203 n.

[2] J. G. Fichte (1971) *J. G. Fichtes sämmtliche Werke*, ed. I. H. Fichte, 8 vols (Berlin: Walter de Gruyter, 1971), vol. IV, 174, trs. D. Breazeale and G. Zöller, *The System of Ethics* (Cambridge: Cambridge University Press, 2005), 165.

[3] For an excellent recent account of the access problem, see Chapter One of Quentin Meillassoux's *After Finitude* (London: Continuum, 2008).

> The transcendental argument must not invalidly infer objective and/or unrestricted conclusions from purely subjective and/or merely parochial premises.[4]

Again, following Fichte, this criterion is expressly designed to counter any claim to a 'transcendental naturalism', which comes close, as Bell claims, to an oxymoron.[5] It follows from the above criterion that the only valid transcendental argument is one that demonstrates and asserts the parochial subjectivism of its premises. What is striking is that the double assertion of subjectivity and parochialism is asserted against the rest of being or nature. We must ask, however, whether the Bell-Fichte subjective parochialism thesis does in fact exhaustively define transcendentalism, so that to reject the one is to dismiss the viability of the other, and thus to assert that there can be no other basis for transcendental philosophy. If this is so, in so far as transcendentalism's parochialism constitutes its putative value, it also constitutes grounds for its rejection. If not, we cannot conclude a transcendental naturalism to be oxymoronic.[6]

---

[4] D. Bell, 'Transcendental Arguments and Non-Naturalistic Anti-Realism', in R. Stern (ed.) *Transcendental Arguments. Problems and Prospects* (Oxford: Oxford University Press, 1999),189-210, at 192.

[5] Ibid., 194.

[6] The prospect of a naturalistically grounded transcendental philosophy is precisely

Consider, for example, Schelling's claim above: It is a transcendental argument in that it stipulates what conditions the possibility of thinking without reducing these conditions to any given or particular domain of objects. Hence Kant's having noted, with regard to Schelling's *System of Transcendental Idealism*, that 'transcendental idealism is realism in an absolute sense'.[7] In accordance with this absolute realism, Schelling's thesis stems from his ontological naturalism:[8] Being is the necessary condition of thinking and not vice versa.

The point to note is that neither claim is inherently inconsistent, that both are transcendental, and accordingly, that transcendental positions are themselves open to counterpositions. Given this, in what follows, we shall argue that transcendental philosophy is itself a dogmatism,[9] and

---

what Kant sought by way of the 'ether proofs' in the *Opus postumum*, trans. by E. Förster, (Cambridge: Cambridge University Press, 1993), 62-99. Transcendental philosophy is then defined as the 'system of *ideas*, which are problematic (not assertoric) in themselves [...] but must nevertheless be thought as possible forces affecting the rational subject' (ibid., 250), necessitating a *dynamica generalis* (ibid., 224) to ground *both* the system of objects *and* the system of ideas.

[7] *Opus postumum*, op. cit., 255.

[8] 'Anything whose conditions simply cannot be given in nature, must be absolutely impossible' (Schelling, *Werke* III, 571). Although it could be argued that the 'positive philosophy' of the *Grounding* is incompatible with the 'negative philosophical' theses of the *System of Transcendental Idealism*, this would be to disguise the extent to which Schelling's naturalism is precisely the kind of 'absolute realism' with which Kant identifies 'transcendental idealism'.

[9] As indeed Fichte claims in the 'Review of *Anesidemus*': 'the [Dogmatic] system holds open the possibility that we might someday be able to go beyond the boundary of the human mind, whereas the Critical system proves that such progress is absolutely impossible, and it shows that the thought of a thing possessing existence and specific properties in itself and apart from any faculty of representation is a piece of whimsy, a pipe dream, a nonthought. And to this extent the Humean system is sceptical and the Critical system is dogmatic – and indeed negatively so' (*W* I, 16; Eng trans. by D. Breazeale in *Fichte: Early Philosophical Writings*, Ithaca: Cornell University Press, 1988, 70-1).

shall do so on the basis of the applicability of three criteria specified by transcendental philosophers for the identification of dogmatism. These criteria are:

C.1 *Logical*: the susceptibility of dogmatic systems to internally consistent but antinomic counter-systems.[10]

C.2 *Metaphysical*: the attempt to provide a ground or cause of beings external to the I, or to satisfy the Principle of Sufficient Reason;[11] and

C.3 *Ontological*: the thesis that beings are things or objects.[12]

---

[10] '[Reason, in] its dogmatic employment [...] lands us in dogmatic assertions to which other assertions, equally specious, can always be opposed' (Kant, *Critique of Pure Reason*, trans. N. Kemp Smith, London: Macmillan, 1958, B22-3; hereafter CPR). '[I]n the dogmatic procedure of reason [...] unavoidable contradictions of reason with itself have long since undermined the authority of every metaphysical system yet propounded' (CPR: A10/B23-4). In 'the dispute between the idealist and the dogmatist [...] reason gives us no principle of choice [... and n]either of these two systems can directly refute its opposite' (Fichte, *Werke* I, 429-432; trans. by P. Heath and J. Lachs, *The Science of Knowledge*, Cambridge: Cambridge University Press, 1982, 12-14).

[11] While metaphysics, 'as science [...] has to deal [...] only with itself and the problems which arise entirely from within itself, and which are imposed upon it by its own nature, not by the nature of things which are distinct from it' (CPR: B23), 'dogmati[sm] claim[s] acquaintance with the constitution of the object fuller than that of the counter-assertion' (CPR: A388). See also Fichte, *Werke* IV, 174; *System of Ethics*, trans. and ed. by Daniel Breazeale and Günter Zöller (Cambridge: Cambridge University Press, 2005), 165: '[T]he fundamental error of dogmatism [...][is to] search outside the I in order to discover the ultimate ground of all that is in and for the I'. Wayne Martin confirms this diagnosis in his *Idealism and Objectivity: Understanding Fichte's Jena Project* (Stanford: Stanford University Press, 1997), 37: 'dogmatists are not identified simply as those who assert that things-in-themselves exist; rather they are those who assert that things in themselves constitute the ground of experience'.

[12] '[*D*]*ogmatic* enquiry concern[s] things (objects), [whereas] a *critical* enquiry concern[s] the limits of my possible knowledge' (CPR: A758/B786). Dogmatism thus 'requires an insight into the nature of the object such that we can maintain the opposite of what the proposition has alleged in regard to this object [...] claiming acquaintance with the constitution of the object fuller than that of the counter-assertion' (CPR: A388). 'Any philosophy is [...] dogmatic, when it equates or opposes any thing to the self as such;

Since (3) can itself be construed as satisfying (2), it may be subsumed under it. Our purpose in stating it separately is threefold. Firstly, to highlight the crucial role played by 'things' not only in the determination of the nature of dogmatism, as above, but also in the development of transcendental philosophy's *ontology*, for which the concept 'thing-in-itself' asserts only the most elementary determination of existents; but transcendental philosophy is itself dogmatic when it concludes that *therefore they exist at all*, and that this is how being is, as when, for instance, it asserts that 'concepts of relation presuppose things which are absolutely [*schlechthin*] given, and without these are impossible'.[13] That is, the condition of possibility of objects of intuition – even of their distinction – is simply 'things absolutely given'. At this point, transcendental philosophy, whose 'supreme concept [...] is the division into the possible and the impossible', can avoid dogmatic ontological commitment only at the cost of antithesis:

> Thus the object of a concept to which no assignable intuition whatsoever corresponds is = nothing. That is, it is a concept without an object (*ens rationis*), like noumena, which cannot be reckoned among the possibilities, although they must not for that reason be declared to be also impossible.[14]

Although the 'things absolutely given' on which the objects of intuition depend are neither possible nor

---

and this it does in appealing to the supposedly higher concept of a thing (*ens*), which is thus quite arbitrarily set up as the absolutely highest conception. In the critical system, a thing is what is posited in the self; in the dogmatic, it is that wherein the self is itself posited' (Fichte, *Werke* I, 119-120; *Science of Knowledge*, 117).

[14] CPR: A290/B346-7.

impossible, and therefore not susceptible of a transcendental investigation, their existence cannot be denied: The very essence of the dialectic, or the unavoidable errors entailed by reason's own nature, we might say. Yet as Kant's naturalistic inquiries continue (the analysis of fundamental forces in the *Metaphysical Foundations*, for example; that work's assuaging of Kant's doubts concerning chemistry as a science, and its possible applicability to emergent neuroscience; or more explicitly, the 'ether proofs' of the *Transition from Metaphysics to Physics*),[15] this possible-impossible determination *that there are things* becomes increasingly open to dispute: Perhaps things are not 'absolutely given', but instead forces assume ontological and explanatory priority over things. At issue here is the susceptibility of parochial (in Bell's sense) transcendentalisms to naturalistically driven ontological change. By criterion (1), then, the revealed contestability of a thing-based ontology demonstrates the transcendental philosophy's propensity for dogmatism.

The second reason for the initial separation of condition (3) from (2) is to accommodate a recent argument made by Wayne Martin concerning Fichte's identification of dogmatists not 'simply as those who assert that things-in-themselves *exist*' but rather as 'those who assert that things-in-themselves *constitute the ground of experience*'; or, in other words, that 'the I is a thing'.[16] Such arguments – properly parochial, in Bell's sense – highlight the implicit assertion that an argument is transcendental if and only if it avoids dogmatic assertion and *therefore* susceptibility to counter-assertion ('things-in-themselves do/do not exist'). Such transcendentalisms therefore tend to propose a metaphysics without ontology. The third and final reason for the initial distinction is therefore to raise the question as to whether this is possible. For dogmatisms, by contrast, argue that *any consistent metaphysics is an ontology, and any consistent ontology is a metaphysics.*

---

[15] See Kant, *Aus Soemmering, Über das Organ der Seele*, *Ak.* XII, 33-7, trans. by Anulf Zweig as 'From Soemmmering's *On the organ of the soul*' in Immanuel Kant, *Anthropology, History and Education*, ed. by Gunter Zöller and Robert Louden (Cambridge: Cambridge University Press, 2007), 219-226; and Alexander Ruerger, 'Brain water, the ether, and the art of constructing systems', *Kant-Studien* 86, 1995: 26-40. The *Transition between Metaphysics and Physics* was the working title by which what became Kant's *Opus postumum* was contemporarily known (cf. Schelling, *Werke* VI, 8).

Consider a metaphysical problem such as causality. When Kant examines self-organisation in the third *Critique*, he makes precisely the claim that its ubiquity in experience cannot warrant any assertion or denial of its existence in nature. Yet this 'problematic' address to natural causality nevertheless finds that it is 'necessary for reason to think' that 'matter can receive more and other forms than it can get through mechanism'.[17] Rational necessity avoids ontological commitment if and only if it does not entail that the theses concerning matter and causation so necessitated are *not* theses concerning matter and causation at all, but only reason; or, in other words, if the thesis, although rationally necessary, is contradictory. If the rational necessity so identified is not to be contradictory, then they are indissociably ontological theses. In other words, a resolutely problematic metaphysics must either satisfy the principle of sufficient reason, or break the law of non-contradiction. Neither, for the same reason, can ontology be separated from metaphysics unless the latter does not concern being at all. If it does not, it can only concern not-being, and is then not metaphysics, but meontology. If it does, then the distinction is untenable. Or ontology is not concerned with being, but with the reason-of-being, its *logos*. Such an account must either again face the problems encountered by Kant's 'rational necessity', or the reason-of-being must become the sole focus of ontological enquiry. This is why many of the immediate post-Kantians understood the transcendental undertaking as a 'critique of natural cognition'[18] or of the 'natural antithetic';[19] that is, an inquiry into the nature of reason itself.

[16] Martin, *Idealism and Objectivity*, op. cit., 36-7.

[17] I. Kant, *Kants gesammelte Schriften* (Henceforth *Ak.*), ed. Königlich Preussischen Akademie der Wissenschaften (Berlin: Georg Riemer, later Walter de Gruyter, 1900-), vol. V, 411; trans. W.S. Pluhar, *Critique of Judgment* (Indianapolis: Hackett, 1987).

It is precisely this that Schelling's thesis about being denies. For it asserts not only that being is the necessary *condition* of thinking, but also that being is *first* necessary *in order that there be* thinking; being is the cause and ground of thinking, so that the Sufficient Reason for thinking is indistinguishable from ontology. Schelling's is, on this reading, a transcendental dogmatism, specifying conditions of possibility by satisfying criteria (1) and (2) above. As to the non-separable criterion (3), Schelling will indeed deny, following from the force-ontologies developed by early experiments in electromagnetism, that 'things' can provide an adequate ontological basis for either the natural sciences or for speculative naturalism. If this is taken to mean that any ontological thesis resting on forces rather than things is for that reason non-dogmatic, then the difference between transcendental and dogmatic naturalisms rests on contingent differences in the ontologies of the natural sciences.

[18] Schelling, *Werke* XI, 526.

[19] CPR: A407/B434.

The dilemma initially facing a transcendental naturalism is accordingly that it must either assert determination by contingent entities of whatever nature (things, forces) or assert parochialism and admit that even in those of its theses that putatively address nature, no such address takes place insofar as the 'nature' in question is *phenomenal only*. The problem with this perhaps over-familiar claim, for those of us steeped in Kantian lore, is that there is an implicit assertion that nature as it is in itself is separable from nature *kat' anthropon*, as Kant says – nature as it appears *for us*. For this asserts in turn that phenomenal nature *is not nature*, which therefore transcendental philosophy *does not and cannot address*. This is exactly the problem that Kant encounters when he attempts the transition, firstly, from the dogmatic naturalism of his pre-critical to the properly critical works; and secondly, from metaphysics to physics in his final accounts of transcendental philosophy. If the Copernican revolution does not resolve this problem, then the problems Kant encountered remain ours: How, if at all, is a nondogmatic account of the relation of reason to nature possible?

1. EVERY CONSISTENT DOGMATISM IS A NATURALISM

> How then is the Critical system different from what was previously described as the Humean one? The difference consists entirely in this: the Humean system holds open the possibility that we might someday be able to go beyond the boundary of the human mind, whereas the Critical system proves that such progress is absolutely impossible, and it shows that the thought of a thing possessing existence and specific properties *in itself* and apart from any faculty of representation is a piece of whimsy, a pipe dream, a nonthought. And to this extent the Humean system is sceptical and the Critical system is dogmatic.[20]

> If thetic be the name for any body of dogmatic doctrines, antithetic may be taken as meaning not dogmatic assertions of the opposite, but the conflict of the doctrines of seemingly dogmatic knowledge in which no one assertion can establish superiority over the other.[21]

It would be a matter of considerable irony that a *Copernican* revolution in philosophy should have put paid to the project of a *Universal Natural History* – were it true. It does not, however; yet this is precisely what it is considered to have achieved: Having put an end to worries about how to adequate intellect to thing, since things must now instead comply with intellect. Yet how is any 'unthinged' naturalism to survive the revolutionary injunction? Are such 'things' reducibly those that are intellect-compliant, or are all things so? Must they be made so? Of necessity or by reconstruction? If the occasion for the revolution is that it has proven impossible to integrate reason with nature as it is in itself, what becomes of the problem of the integration of reason and nature after it?

It is immediately evident that not only does the problem of nature not disappear from the transcendental philosophy, but also that, as the critical project progresses, it resumes the central role it enjoyed under Kant's precritical or dogmatic-naturalist period. The engagement with chemistry in the first *Critique*, which persisted long afterward;[22] the problem of the teleological judgment of nature with regard to the *actuality* of self-organising beings in the third. But nowhere is this cohabitation of dogmatic naturalism with transcendental philosophy more immediate than in Kant's final, unfinished project, known under the title *Transition from Metaphysics to Physics*,[23] with its ether deductions and its attempt to square transcendental deduction with *ontogenesis*.[24]

Friedman, *Kant and the Exact Sciences* (Cambridge: Harvard University Press, 1992), E. Watkins (ed.) *Kant and the Sciences* (Oxford: Oxford University Press, 2001), and M. Friedman and A. Nordmann (eds), *The Kantian Legacy in Nineteenth-Century Science* (Cambridge: MIT, 2006). For a substantial philosophical account of the persistence of naturalism in the critical philosophy, see J. Edwards, *Substance, Force and the Possibility of Knowledge* (Berkeley: University of California Press, 2000), and for the naturalism in the *Opus postumum*, E. Förster, *Kant's Final Synthesis* (Cambridge: Harvard University Press, 2000). For my own account of the conflict between somatism and field physics in Kant's philosophy of nature, see *Philosophies of Nature After Schelling*, 2nd edition (London: Continuum, 2008).

[23] Schelling, *Werke* VI, 8: 'In the year 1801 he [Kant] was still labouring, in those few hours in which his power of thinking remained free, on a work: *Transition from Metaphysics to Physics* which, had age allowed him to complete it, would doubtless have been of the greatest interest.'

[24] What I have in mind here is the *Transition*'s discussions of 'how matter becomes a physical body' (Kant, *Ak.* XXI, 476-7). I discuss this in *Philosophies of Nature after Schelling*, op. cit., 59-81.

Allowing that the Copernican revolution was expressly undertaken to eradicate (at least Kant's) dogmatic naturalism; and acknowledging also that the problem Kant held dogmatism incapable of resolving is the integration of reason and nature into a single and consistent philosophical system; then the purpose of the critical philosophy is to prepare a transcendental resolution of reason and nature. The beginnings of this can be seen in the first *Critique*'s account of nature as 'the dynamical whole of all appearances', as opposed to 'world', which designates 'the mathematical sum-total' thereof.[25] Dynamics is invariably the means whereby the transcendental philosophy undertakes to avoid the fate of dogmatic naturalism without eliminating nature. Force-fields provide, by disputing criterion (3), above, egress from dogmatism without sacrificing nature, while the dynamical categories enable a reconstruction of reason as itself a dynamical and productive system. In the overt transcendental naturalism of the ether deductions, ether will finally integrate freedom with natural causality in a single, necessary and a priori, physical medium, long after the failure of the third *Critique*'s analogical attempt to achieve the same end. Of the ether, Kant writes that

> the question is whether it is to be regarded, not just as a *hypothetical material*, in order to explain certain appearances, but a real world-material – given *a priori* by reason and counting as a principle of the possibility of the experience of the system of moving forces [...] The existence of this material, and the necessity of its *a priori* presupposition, I now prove *a priori* in the following manner.[26]

---

[25] CPR: A418-9/B446.

[26] Kant, *Ak.* XXI, 216; *Opus postumum*, ed. and tr. Eckhart Förster (Cambridge:

With this, Kant seems to condemn his physics to the same fate as his geometry: Changes in the sciences apparently undermine the a priori necessities Kant ascribes to their theses. At the same time, therefore, the transcendental project in general is opened to charges of dogmatism on the grounds of susceptibility to antinomic dispute. Yet the reason why Kant argues for the a priori necessity of the ether as world-material is this: that *dynamics composes being from actions, not things.* As Kant writes, 'the moving forces of matter are what the moving subject itself does to [other] bodies'.[27] The twofold gambit of this claim, as of any transcendental naturalism, is that the transition from things to actions is sufficient both to avoid dogmatic traps concerning antithetical ontologies of things-in-themselves (are such disputes only possible between rival claims as to the nature of *things*?); and to integrate reason and nature into a single system susceptible to determination by free and self-constitutive acts (ontogenesis, categorial synthesis, etc.), now cast as causes. The problem is *whether the transcendental determination of nature is in fact a determination of nature at all*, i.e., a determination 'at once *a priori* and physically conditioned',[28] or merely a determination of the nature of Reason. If nature is *not* so determined, then things are not intellect-compliant, and dogmatism's inconclusiveness or revisability becomes the price to pay for the failure of the Copernican experiment. If it *is*, then the question is *either*: What kind of nature is it that is directly determinable in accordance, as Kant twice stipulates, with the 'power of

desire' as cause?;[29] *or*: What is the nature of reason such that it can so determine nature?

It is freedom and/or reason – or their *necessary combination*, as Fichte was first to point out – that denaturalises as a precondition of nature taken as an objective of transcendental philosophy. Accordingly, transcendental anti-naturalism has its avatars: Heidegger, for instance, in *On the Essence of Ground* (1929), comparing the dogmatic with the transcendental concept of 'world' in Kant's *Inaugural Dissertation* and first *Critique*, respectively, concludes in strict accordance with the replacement of the dogmatist's things with actions, that 'world never *is*, but *worlds*'.[30] Thus 'there are reasons' why, Heidegger insists, 'nature is apparently missing [from this account], not only nature as an object of natural science, but also nature in an originary sense':[31] Nature is not original, but only appears as a determination of world *for* a form of attention paid to it.

While Heidegger's remains a Copernican transcendentalism, Husserl's 1934 work 'Foundational Investigations of the Phenomenological Origin of the Spatiality of Nature: The Originary Ark, the Earth, Does not Move' reverts to a more Cartesian, or *Archimedean* strategy. In a reprise of the first of the antinomies of pure reason,[32] the essay begins the search for a 'a transcendental theory of natural scientific knowledge'[33] by arguing *against* the 'absurdity – indeed, the absurdity' of naturalistic accounts of the origins of world, and *for* a world that is instead constituted by and for experience. Nature and its causes are not things, but 'elaborated intuitions', and *for experience*, indeed, as its condition, the Earth, even as a body, *does not move*. The paradox is alarming: What began with the Copernican revolution has returned, on transcendental grounds, to Ptolemaic geocentrism, to a 'restitution of a sense of the earth as ground beyond Copernicus', as Merleau-Ponty describes Husserl's undertaking.[34]

Such transcendentalisms amplify their Kantian inheritance, and in particular the problem of whether a transcendental naturalism *can supply* a naturalism at all. In light of these latter examples, the answer would clearly be in the negative. For precisely this reason, the post-Kantian fate of the transcendental project reveals something about that project in turn – its susceptibility to antinomy:

THESIS	**ANTITHESIS**
Nature precedes the thinking it spawns	Thinking precedes the Nature it thinks

What is important to note is that the antinomy revolves around the problem of ontological as opposed to conscious priority, just as Schelling's thesis stipulates. A naturalistic ontological solution will therefore think this priority in terms of physical conditionality, while a transcendental anti-naturalist solution will, by contrast, think it in terms of the co-natality of *Ich* and *nicht-Ich* (Fichte), of experience and its ground (Husserl), or of the priority of projection over world (Heidegger). We will return to these solutions below.

---

[33] E. Husserl, 'Foundational Investigations of the Phenomenological Origin of the Spatiality of Nature: The Originary Ark, the Earth, Does not Move' (1934) in Maurice Merleau-Ponty, *Husserl at the Limits of Phenomenology*, trans. and ed. Leonard Lawlor and Bettina Bergo (Evanston: Northwestern University Press, 2002), 117-131: 117)

[34] Ibid., 67.

The antinomy or 'natural antithetic' echoes either side of the transition in Kant's own work from dogmatic to transcendental naturalism. For example, the *Universal Natural History* provides reasons for the critical project that are themselves naturalistic:

> If one looks for the cause of impediments, which keep human nature in such a deep debasement, it will be found in the crudeness of the matter into which his intellectual [*geistige*] part is sunk, in the unbending of the fibres and in the sluggishness and immobility of fluids which should obey its stirrings. The nerves and fluids of his brain deliver only gross and unclear concepts [...].[35]

In this light, Kant's post-Copernican attention is directed not away from nature, but towards the nature of 'self-constituting' reason,[36] a 'natural dialectic'. In the above passage, nature clearly conditions thinking; while in the post-Copernican period, the causes of such impediments are found to 'aris[e] from the very nature of our reason'.[37] Thus we have a first element, corresponding to criterion (1) above, in a definition of the dogmatism it is the Copernican project to supplant:

---

[35] Kant, *Ak.* I, 356.

[36] 'Transcendental philosophy is the autonomy of ideas, insofar as they form, independently of everything empirical, an unconditioned whole, and reason constitutes itself to the latter as a separate system' (Kant, *Ak.* XXI, 79; *Opus postumum*, op. cit., 246). This is also clear from CPR, where Kant defines critical philosophy as that 'science [which] has to deal [...] only with itself and the problems which arise entirely from within itself, and which are imposed upon it by its own nature, not by the nature of things which are distinct from it' (B23).

D.1 *Any philosophy is dogmatic whose theses can be antinomically disputed.*[38]

It follows from this that, if transcendental theses are susceptible to antinomy, their assertion is dogmatic. Since they are so susceptible, then it cannot be concluded that the Copernican revolution entails the elimination of dogmatism, which is why naturalism remains a problem for transcendental philosophy.

A second element towards a definition of dogmatism may also be drawn from Kant's neuro-anatomical critique of human reason. It is clear from the above passage, as well as from other works of the 1750s and 60s, that the dogmatism at issue during the critical revolution is indeed any metaphysics that might support a *dogmatic naturalism*. On one view, the critique of such naturalism attests to Kant's conversion to the 'experimental method' in the consideration of nature, leaving all a priori reasonings regarding nature blinded by their want of experimentally derived intuitive content. On another, however, it is not empty concepts but the determination of causes that presents the problem. The *Universal Natural History* makes it clear that the causes of conceptual confusion are the materials from which the brain is composed. 'Dogmatism in its pure form is materialism', wrote Hegel.[39] It is not that this must necessarily be wrong, but rather that the determination of the specific causes of contingent things is held to determine reason in turn. That is, if a contingent neural architecture (others are conceivable) is responsible for unclear concepts, then reasoning concerning concepts is duly inflected by such neurology. This is why the first *Critique* stipulates that while the proper means for 'determining the limits of [all] possible knowledge' are a priori, 'when my ignorance is contingent [*zufällig*] it must incite me [...] to a dogmatic enquiry concerning things (objects)'[40] – precisely because it is the principle of the Copernican revolution that it is not objects that determine thought, but rather thought that determines objectality. Fichte makes the point explicitly:

---

[37] CPR: A669/B697.

[38] '[The] dogmatic employment [of reason ...] lands us in dogmatic assertions to which other assertions, equally specious, can always be opposed' (CPR: B23).

> It is by the *principle of causality* that dogmatism wishes to explain this nature of intelligence in general, as well as its particular determinations.[41]

This is extremely telling: Not only does it clarify the reasons for Kant's apparent abandonment of the geological, cosmological and mechanical investigations that preoccupied him during his precritical period, but specifies a dimension of dogmatism that, though often overlooked, remains crucial in the struggles of the post-Kantian philosophers against the mechanistic materialism then migrating from the natural sciences into philosophy (hence Fichte's constant complaints against Spinoza).

[40] CPR: A758/B786.

[41] Fichte, *Werke* I, 436; *The Science of Knowledge*, ed. and tr. Peter Heath and John Lachs (Cambridge: Cambridge University Press, 1982), 17.

D.2 *Any philosophy is dogmatic for which (physical) contingencies determine the possibilities of reason*

It should be noted that D.2 adds to C.2 and 3, insofar as the latter stipulate that dogmatism locates the ground of being in things, which D.2 recasts in terms of determinability. Thus, rather than rejecting the world of physically contingent states of affairs, transcendental naturalism will, on the above grounds, argue for the primacy of actions determining by free causes over objects determined in accordance with necessity.

2. THE NECESSARY INDETERMINACY OF BEING

The claim that dogmatism is in fact dogmatic naturalism is supported not only by Kant's overt assertion that dogmatism always entails the assumption of the principle of (efficient) causality in its explanations,[42] that is, of the things (*cosa*) which ground experience, but also by subsequent anti-dogmatist philosophers, chief amongst whom is Fichte. Yet the rejection of causal explanations in metaphysics is only one element of a transcendental naturalism designed to replace it; an additional, *ontological* part of this programme derives from Kant's critique of the primacy of the law of non-contradiction, initially presented in the *New Elucidation* (1755). Proposition I of that work states that 'there is no unique, absolutely first, universal principle of all truths'.[43] The ground of this argument stems from the problems into which basic ontological propositions fall if the law of non-contradiction is held to fulfil the office of such a principle. Drawing on Parmenidean propositions (what is, is; what is not, is not), Kant argues that any truly simple proposition must be either affirmative or negative. If the one, then not the other, and so neither can be universal, since an affirmative proposition cannot be the principle of a negative one, and vice versa. Even the proposition that might be held indirectly to prove the above assertion false, namely, that 'everything of which the opposite is false, is true',[44] is itself an affirmative rather than a negative proposition; just as its antithesis, that is, 'everything of which the opposite is true, is false', is a negative one. Since neither can be derived from its antithesis, neither could have a foundation save in itself, from which it follows that there are two propositions, rather than one unique one. Moreover, from the combination of these two propositions the principle of identity is derived. Kant states this concisely in the following terms: 'whatever is, is, and whatever is not, is not'.[45] The principle of identity is *synthetic* and *necessarily true*, but not a priori, insofar as the principle maintains the difference between being true of reason and being true of things.

---

[42] See, for example, Kant's attempts to determine the causes involved in a putative alteration of the Earth's axial rotation (*Ak.* I, 183-191) and of 'The Age of the Earth, physically considered' (*Ak.* I, 193-214). Critically reflecting on this procedure in the Antinomy of pure reason, Kant writes: 'the assertions of the thesis, on the other hand, presuppose, in addition to the empirical mode of explanation employed within the series of appearances, intelligible [*intellektuelle*] beginnings; and to this extent its maxim is complex. But as its essential and distinguishing characteristic is the presupposition of intelligible beginnings, I shall entitle it the dogmatism of pure reason' (CPR A466/B494). Finally, in the *Critique of Judgment*, Kant notes: 'Now as we talk about the systems that try to explain nature as concerns final causes, we must note carefully that the dispute among all of them is dogmatic – i.e., the dispute is about objective principles concerning the possibility of things, whether through causes that act intentially or only those that act unintentionally' (*Ak.* V, 391).

---

[43] Kant, *Ak.* I, 388; *Theoretical Philosophy 1755-1770*, trans. and ed. by David Walford and Ralf Meerbote (Cambridge: Cambridge University Press, 1992), 6.

[44] *Ibid.*

[45] Kant, *Ak.* I, 389; *Theoretical Philosophy*, op. cit., 7.

The pertinence of Kant's adoption of this Parmenidean couple[46] consists in its abandonment of a *single* first principle, and its replacement with *two* such principles on the one hand, and their *derived synthesis* in the Principle of Identity on the other. This synthetic aspect is further borne out when we consider the place of existence [*Dasein*] and not-being [*Nichtsein*] in the first *Critique*'s Categories of Modality.[47]

TABLE OF CATEGORIES

I *Of Quantity*:	Unity	Plurality	Totality
II *Of Quality*:	Reality	Negation	Limitation
III *Of Relation*:	Of Inherence and Subsistence	Of Causality and Dependence	Of Community (Reciprocity)
IV *Of Modality*:	Possibility-Impossibility	Existence-Nonexistence	Necessity-Contingency

In the considerations concerning the Table of Categories added in the B-Edition, Kant asserts that Modality and Relation belong to the *dynamical* categories, Quality and Quantity to the *mathematical*. The distinction is significant since the latter are concerned with objects of intuition and the former with their *existence*. In all cases, Kant notes, 'the third category in each class always arises from the combination of the second category with the first'. According to the Categories of Modality, then, 'necessity is just the existence which is given through possibility itself'.[48] This reiterates what the *New Elucidation* had already affirmed: that existence is necessary and non-existence impossible.

---

[46] Parmenides DK 28 B2: 'the only ways of inquiry to be acknowledged are: one, that <that which is> is, and it is impossible for it not to be [...] another, that It is not, and must needs not be – this, I tell you, is a path that is utterly indiscernible, for you could not know that which is not, for that is impossible, nor utter it'. I follow Cornford's translation and insertion, *Plato and Parmenides* (London: Routledge and Kegan Paul, 1939), 30-31. Importantly, Parmenides' argumentation proceeds by antitheticals, a procedure that Plato's *Parmenides* repeats and of which Kant's dialectic is a direct heir.

[47] CPR: A80/B106.

Descending from the synthetic, while 'all a priori division of concepts must be made by dichotomy',[49] the dynamical categories operate by *dichotomous antitheses* of concepts. On the scale of systems rather than concepts, the principle of identity explicitly sanctions extra-systemic contradictions between those that are affirmatively and those that are negatively grounded, setting up the problem the Transcendental Dialectic examines between antinomic systems. To these formal concerns, the *New Elucidation*'s protocritical yet still dogmatic argumentation adds a material element: In keeping with its Parmenidean source, Kant draws expressly *ontological* consequences from the principle of identity. It is not the identity of any particular content that is established by the principle, but rather the primary differentiation of being from not-being, and therefore the identity of what is as what is. Both principles are self-identical, insofar as their contraries facilitate no derivation: 'Being is not', that is, does not yield any derivables, not even nothing.[50]

---

[48] Ibid., B110-111.

[49] Ibid., B110.

[50] Kant expressly disputes that the product of a contradiction is nothing: '"+ A – A = 0", [or i]n other words, affirming and negating the same thing is impossible or [*sive*] nothing' is true iff 'you invest the sign of the negative concept with the power of cancelling [*vim tollat*] the affirmative concept' (*Ak.* I, 390; 1992: 9). This power of cancellation, however, is precisely what the principle of contradiction presupposes, but that the principle of identity denies as active between assertions and negations. With no such power, nothing cannot derive from the combination of something with something that is not. The power of cancellation operates only between identicals, so that Kant rephrases the principle of identity thus: '*whatever is not not, is*', where the two 'nots' cancel each other out (*Ak.* I, 389; 1992: 8). In effect, Kant is arguing that the impossible is not nothing, but is impossible.

Accordingly, 'whatever is *not not*, *is*'[51] avoids the trap of asserting the being of what is not, or of asserting the being of 'not-being' (Parmenides' 'way of opinion').

Ontologically, the important consequence of both this Parmenidean and modal argumentation is that *all predication is of what is* and *no predication can be of what is not*. Being is not therefore a predicate, as the critical Kant will assert,[52] but rather that of which all predicates are predicates, the referent or *Bedeutung* of all predication, regardless of its *Sinn*.[53] In other words, no information is or can be given as to what is: all that is specified concerning being is that it is *impossible* that it is not. This modal account is an important first element of the ontology transcendental philosophy presupposes but cannot own without reverting to dogmatism. The elucidation of this ontology will therefore demonstrate that transcendentalism offers a new species of dogmatism in philosophy.

We are not alone in affirming an ontology underlying the transcendental project. For example, Heidegger notes in his address to 'Kant's Thesis About Being', that the thesis at issue does not affirm that beings or *things* are, and thus does not even inform us as to whether being is comprised solely of beings. All Kant's thesis tells us is that 'being is obviously not a real predicate'. Heidegger identifies this as the 'negative thesis about being'.[54] The 'positive thesis', by contrast, characterises being as

---

[51] Kant, *Ak.* I, 389; *Theoretical Philosophy*, op. cit., 8.

[52] CPR: A598/B626.

[53] This elicits a dimension often overlooked in the Fregean account of the *Bedeutungen* of propositions. In 'On *Sinn* and *Bedeutung*' (1892), Frege writes 'all true sentences have the same *Bedeutung*' (in Beaney [ed.] *The Frege Reader* [Oxford: Blackwell, 2000], 159), namely, as the 'Comments' on that essay (1892) make clear, 'the True'. Just as Kant claims all predication is of being, so Frege argues that since all propositions aim at the True, 'thought and Being are the same' (ibid., 174). Finally, in 'Thought' (1919), Frege generalizes this account to the classical Platonic triumvirate: 'Just as "beautiful" points the way for aesthetics and "good" for ethics, so do words like "true" for logic' (ibid., 325).

> the positing of a thing, of certain determinations as existing in themselves. [55]

From this we gain a sense of the dogmatism inherent in ontological determination, while at the same time the properly critical element is foregrounded. In this late analysis of Kant's ontology,[56] Heidegger takes the entirety of the above proposition as constituting the 'positive assertion', despite its containing two distinct – and perhaps antithetical – sub-theses: First, being is identified with *positing*; second, positing is identified not only with determination, but with determinations 'as *existing in themselves*'. That the first sub-thesis fulfils the critical requirements of this ontology is evident from the *positing*: It is not that things are in this or that way that makes the proposition a transcendental one, but the *positing* of things as this or that mode of existence (*agit, facit, operatur, dirigit*).[57] That this is so will become especially evident not only in the *Selbstsetzungslehre* and the 'Ether deductions' of the *Opus postumum*, but also in

---

[54] M. Heidegger 'Kant's thesis about being', op. cit.

[55] CPR: A598/B626.

[56] Heidegger's first published examination of Kant's ontology is *Kant and the Problem of Metaphysics* (1929, trans. by R. Taft, Bloomington: Indiana University Press, 1997), an analysis to which he returns in 'Kant's Thesis about Being' (1961) and *What is a Thing?* (1962, trans. by W. B. Barton and V. Deutsch, Chicago: Regnery, 1968).

[57] 'Nature *causes* (*agit*). Man *does* (*facit*). The rational subject acting with consciousness of purpose *operates* (*operatur*). An intelligent cause, not accessible to the senses, *directs* (*dirigit*).' (Kant, *Ak.* XXI,18; *Opus postumum*, 224-5)

Kant's heirs' (especially Fichte's) accounts of the constitutive or determining role of the *act* of positing with regard to the *facts* so posited. Against these Copernican credentials, the second sub-thesis automatically triggers accusations of dogmatism, at least insofar as the term applies to all metaphysics that takes as its object the determination of things 'existing in themselves'.

The question then concerns the relation between the two sub-theses; whether, that is, the first sub-thesis's identification of being with positing is identical with or different from the second sub-thesis's identification of positing and determination. If it is, then being is determinable *in itself* by positing; if not, then the being of the positing is not equivalent to the determination so posited. Note that from the thesis that being is what all predication is of, it follows that all predication must be the determination of being. Meanwhile, positing posits *determinations* as 'existing in themselves'. It does not, that is, determine anything *that* exists in itself, but *makes* determinations exist in themselves. In effect, this is what a second constituent of Kant's modal ontology stipulates: 'I have been reproached', Kant writes,

> for defining the power of desire as the power of being the cause, through one's presentations, of the actuality of the objects of these presentations [*die Definition des Begehrungsvermögens als Vermögens, durch seine Vorstellungen Ursache von der Wirklichkeit der Gegenstände dieser Vorstellungen zu sein*].[58]

Just as the thesis that all predication is of what is critically buttresses the *New Elucidation*'s modal proposition concerning being, viz., that it is impossible that it is not, so the thesis that being is a positing of determinations existing in themselves turns into an account of the determining causes of *actuality*. From this, we derive an initial statement of Kant's ontology:

---

[58] Kant, *Ak*. V, 177 n., citing *Ak*.V, 9 n.

Being is necessarily indeterminate if actuality is determinable.

Or, in practical terms:

The necessity of contingency is necessary for the determinability of the actual.

It is precisely at this juncture that a comment Hegel makes in the *Difference Between Fichte's and Schelling's System of Philosophy* with regard to Kant's table of categories acquires significance as regards the investigation of a transcendental dogmatism. The framing of Hegel's comment is, in this regard, especially instructive. In Kant's deduction,

> The identity of subject and object is limited to twelve acts of pure thought [*reine Denkthätigkeiten*] – or rather to nine only, for modality really determines nothing objectively; the nonidentity of subject and object essentially pertains to it.[59]

Firstly, that the categories are to fulfil the 'identity of subject and object', that is, satisfy the speculative proposition, may seem like Hegel's own imposition. Yet it is Kant who stipulates that, although the categories in general constitute 'all original pure concepts of synthesis that the understanding contains within itself *a priori*',[60] the dynamical categories are in addition 'concerned with existence'.[61]

---

[59] Hegel, *The Difference Between Fichte's and Schelling's System of Philosophy*, op. cit., 80.

[60] CPR: A80/B104.

[61] Ibid., B110.

With what existence? Categories or acts of thought that had no such effects could satisfy no subject-object or concept-intuition identity. In other words, although the categories cannot determine a priori the existence and specific differentia of particular matters, the categories of modality are nonetheless held to posit 'determinations existing in themselves'. Yet we have seen how the transcendental philosophy demonstrates the necessity attaching to existence as the ground for its determination, which extends, in the form of practical reason, to the determination of actuality (*Wirklichkeit*) as such. Why then does Hegel expressly deny this determination, asserting instead that Kant's categories of modality 'determine nothing objectively' and that 'the nonidentity of subject and object essentially pertain to it'?

The criticism hinges on the claim that the categories of modality, *qua* categories of the understanding, are determining only of forms of thought, and thus provide a merely subjective determination of actuality. Hence it can be denied that anything is thereby determined *objectively*. Further, this is necessarily the case insofar as these categories are premised on the non-identity of subject and object, which the ontology supporting the Copernican revolution presupposes: The determination of reason is simply not the determination of things. In other words, if it is through the *positing* that 'determinations exist in themselves', then these determinations have existence only consequent upon their positing. Since, at the same time, no determinations can be made of things-in-themselves, then the categories of modality, especially those of existence and non-existence, 'determine nothing objectively'.

While possessing no capacity for objective determination, the categories do nevertheless determine the *only possible actions* that speculative reason can perform, *regardless of whether such performances obtain* or are *actualised*. As we have seen, the transition to *actuality* is not an element of speculative reason, but a power only practical reason can effect. To effect is ultimately to determine actuality in accordance with freedom as the only *unconditioned* and *necessary* cause.[62] Accordingly, since it is a necessary presupposition of the Copernican revolution that being is determinable but not determining, being so determined is actuality: Subjectivity remains impotent in being, but powerful in actuality.[63] The reason for this is the Copernican thesis that objects are determinable for reason while reason is not determinable by objects, which entails that objective determination – that is, determination of existents anterior to determination – is impossible. Neither existence nor any of the other categories can therefore be extended to objects as such, but only to actuality, by positing. If being has no 'objective' side, in what then does nature consist? Grasping the implications, it is Fichte who is Kant's true heir, exactly as he claimed, when, in the *Science of Knowledge*, he characterises the object for the subject as the *nicht-Ich*, finally subjectivising all nature. 'Is it true' then, as Georges Cuvier asked his erstwhile professor of comparative anatomy, Carl Friedrich Kielmeyer, 'as the Kantians seem to maintain', that

---

[62] Ibid., A418-9/B446-7.

[63] Kant was never as clear as Fichte about this: 'if the Science of Knowledge should be asked, how then, indeed, are things-in-themselves constituted, it could offer no other answer save, as we are to make them. [… H]ence we can never speak of the existence of an object without a subject' (Fichte, *Werke* I: 286; *Science of Knowledge*: 252).

> external nature [...] may be deduced from *a priori* principles, i.e., those that are present prior to all experience [...] – in short, from the nature of our minds [?][64]

The problem is excellently posed: if there are principles prior to all experience, then external nature emerges only *after* its subjective determination. Thus Hegel's intervention clarifies the ontology presupposed by transcendentalism, and articulates its dichotomous structure: Nature cannot be objectively but only subjectively determined; therefore objective nature is of necessity objectively indeterminate in itself. By contrast, Cuvier's problem suggests that it is only if the deduction of external nature is *not* the deduction of external nature that a subject-object dichotomy is conceivable. Rather than the subject-object pair, the Cuvier question (so like Jacobi's challenge to Kant)[65] works out the implications of the priority of thinking over being asserted by transcendental naturalism. Both sets of concerns, however, present an antinomy of transcendental naturalism: The opposability of transcendental to dogmatic naturalism, on the one hand, and the priority of thinking over being, on the other. Since these theses are opposable, transcendental ontology is dogmatic by criterion (1), above. Nevertheless, the core problem of the identity of reason and nature remains open. As for all dogmatisms, therefore, transcendentalism is a naturalism concerned not with the determination of mind by nature, but with that of nature by free causes supported by necessary contingency. We will now examine both the Hegelian and the Cuverian antinomies of transcendental naturalism in turn.

Jacobi, 'Realism and Idealism', in B.Sassen (ed.), *Kant's Early Critics: the Empiricist Critique of the Theoretical Philosophy* (Cambridge: Cambridge University Press, 2000), 175.

3. THE ANTINOMIES OF TRANSCENDENTAL NATURALISM

I. THE HEGELIAN ANTINOMY

Hegel presents an antinomy of transcendental naturalism in *The Difference between Fichte's and Schelling's System of Philosophy*, through Fichte's transcendental deduction of nature. The deduction is transcendental insofar as its starting point is the absolute *Ich*'s oppositing of nature to the empirical *Ich*, or the 'self-limitation of free activity'.[66] In other words, the differential between the absolute and the finite *Ich*s, or the degree to which the latter approximates the absolute identity of the former, provides the necessary conditions for thinking nature in accordance with the programme of the *Science of Knowledge*. Hegel[67] cites Fichte postulating that nature

> is characterised by its antithesis to freedom. 'Nature determines itself' must [accordingly] be translated into 'nature *is* determined by its essence, *formaliter*, to determine itself'; nature can never be indeterminate, as a free being can very well be; and *materialiter* too, nature is determined just in one way and no other; unlike a free being, it does not have the choice between a certain determination and its opposite.[68]

---

[66] Hegel, *The Difference Between Fichte's and Schelling's System of Philosophy*, op. cit., 136.

[67] Ibid., 137-8.

[68] Fichte, *Werke* IV, 112-3; *The System of Ethics*, op. cit., 108.

Fichte here makes explicit the necessary indeterminacy of being that is merely implicit in Kant, and applies this to the production of a nature as formal and material *being-determined*. Accordingly, nature *is* formal and material determinability. The determinable is never possibly not-determined, so that the empirical *Ich* can never not be determined in turn by determinacies it posits as its own limits. Empirical or living self-consciousness therefore sets itself as its task an unlimited striving to overcome these limits and increase the indeterminacy of or in being.

Because striving takes *time*, and because it must be *unlimited* if it is a free striving rather than a determined and therefore merely natural drive, Hegel complains that rather than resolving the antithesis of nature and freedom, Fichte replaces it with an antithesis between 'a limited present and an infinity extraneous to it'.[69] Replacing an 'absolute object' with an absolute subject merely produces, notes Hegel, a 'dogmatic idealism';[70] antinomising it by way of a living self-consciousness generates no solution, therefore, to the antithesis of nature and freedom, but transposes the ground of this antithesis outside itself, a subjectivity as objective and absolute as the object of dogmatic materialisms. This is borne out by Fichte's concept of 'drive', drawn from physiological researches into the nature of living beings. Thus, he writes:

> The highest exhibition of intelligence outside itself, in nature, is the drive.[71]

---

[69] Hegel, *The Difference Between Fichte's and Schelling's System of Philosophy*, op. cit., 139.

[70] Ibid., 127.

[71] Fichte, *Werke* XI, 363.

Positing the drive as the highest exhibition of intelligence in nature – rather than, for example, the closest nature gets to exhibiting intelligence – therefore clearly exhibits transcendental dogmatism's maintenance of the dichotomy, while at the same time demonstrating the site of the struggle over determinacy versus purpose, between physics and ideality. Fichte reconstructs ethics as the direct conflict of matter and ideality, as the infinitely unresolvable struggle of embodied determinacy for absolute indetermination, and thus posits 'Nature [as] something essentially determined and lifeless'.[72] Nothing demonstrates more concretely this antinomy of transcendental naturalism than the 'shock of the objective world',[73] or nature determined as absolute object.

Hegel's own solution follows from a view of Kant's transcendentalism he shares with Schelling. That is, when reason takes itself as its own object, transcendental philosophy is the investigation of the nature proper to reason. Accordingly, the Hegelian solution to the antinomy concerns the latter's provocation of the need of philosophy to overcome dichotomy. Yet Reason *by its own nature* is driven to maintain the dichotomy in and as its identity with the Absolute. The 'speculative proposition' that satisfies this need always and necessarily asserts identity with the Absolute (Frege's Hegelianism), but never equivalence to it, so that the 'identity of identity and dichotomy' resolves the antinomy of finitude and extrinsic infinity.

Therefore it is a condition of Reason's nature that it is *both* unconditioned by the dichotomy of freedom and nature, *and* maintains it. This is an important solution in three ways. Firstly, Hegel's is a species of *naturalised epistemogenesis* in accordance, as both the Greater *Logic* and the *Phenomenology* show, with living reason. Secondly, it is a largely forgotten solution to a problem that remains unresolved: namely, the relation of reason to nature, on the one hand, given the nature of reason on the other. Speculative idealism, in this regard, shares its concerns with philosophical inquiries regarding naturalised epistemology, neurophilosophy, and dialethism,[74] amongst others. Thirdly, Hegel's proposals do not resolve but amplify antinomy, making his a hyperdogmatism that remains undetermined with regard to nature or reason.

---

[72] Hegel, *The Difference Between Fichte's and Schelling's System of Philosophy*, op. cit., 139.

[73] Schelling, *Werke* I, 337.

II. THE CUVERIAN ANTINOMY

Let us then return to the indeterminacy of being thesis common to transcendentalism in general. If what is at stake, for Fichte, is the relative determinability of the *Ich* and its opposited 'nature'; and if, for Hegel, it is the determinability of all dichotomy by Reason's nature that matters, then transcendental philosophy has, in the 'positing' principle considered above, a naturalistic means for accounting for determination. We will first investigate this before pursuing the Cuverian antinomy of transcendental naturalism.

---

[74] For naturalised epistemology, see W. V. O. Quine 'Epistemology naturalized' in *Ontological Relativity and Other Essays* (New York: Columbia University Press, 1969). For neurophilosophy, see P. M. Churchland, *Neurophilosophy* (Cambridge: MIT, 1986), 482: 'so it is that the brain investigates the brain, theorizing about what brains do when they theorize'. Graham Priest, in *Beyond the Limits of Thought* (Oxford: Oxford University Press, 2002), defines dialethism as a transcendental investigation into the nature of true contradictions.

Positing is an *act*, the actualisation of a power in the world, subject to resistances and limitations. If nature or being is able to impose resistances and limitations upon subjectivity, philosophy returns to pre-Copernican dogmatic naturalism. Thus the antidogmatic critique of causation consists in a refutation of its capacity to determine reason. To be so capable, a thing or cause (*causa*) would have to be ascribed powers; without a thing-in-itself as their possessor or vehicle, there remains only a set of powers. If a powers ontology is generalised, and if determination is a power of reason, then reason acts in one and the same world as do other powers. As Warnke notes,

> *Actions* are conceived by traditional metaphysics as the *expressions of things.* [Transcendentalism] stands this common view on its head [and] determines *things as expressions of actions, objects* as products of *relations*, *being* as a reified, objectified *doing*, exhausted in its product.[75]

Considered along these lines, the powers or *Vermögen* of the first *Critique*, held responsible as they are for the existence or actuality of determinations, constitute a step towards supplanting bodies with forces in fundamental physics. This, for example, is how the medical scientist Andreas Röschlaub read Fichte, rendering the latter capable of a philosophy of medicine,[76] and how the natural historian Carl Friedrich Kielmeyer reports the substance of Kant's Copernican revolution to Cuvier:

---

[75] C. Warnke, 'Schellings Idee und Theorie des Organismus und der Paradigmawechsel der Biologie um die Wende zum 19. Jahrhundert' in *Jarhrbuch für Geschichte und Theorie der Biologie* 5, 1998: 187-234: 200.

[76] Developing the theme of Idealist influences in their contemporaneous sciences, Tsouyopoulos (1978: 90) cites Röschlaub's assessment of transcendental naturalism from the latter's *Magazine for the Improvement of Medicine* vol.8, part 3 (1805): 473: 'The philosophemes of a Kant, a Fichte and a Schelling have given the labours of the physician and the natural scientist a manifest and proper direction in our own day, just as the philosophemes of Empedocles, Democritus, Heraclitus and Aristotle did earlier'.

> This experiment of Kant's is astute, and it recommends itself in that in this way, the necessary, the universal and the certain in our knowledge remains subjective in our mind, while the contingent and the particular will be attributed to objective nature, which is unknown in itself. [77]

As for Kant, then, although he allows no naïve knowledge of nature 'in itself', Kielmeyer's ontology is modal, consisting of what necessarily and what contingently is. Objective nature is not nature-as-objects but as *matter* and, as matter, is subject to further determination by forces. Here Kielmeyer joins Hegel in asserting that Kant does not go far enough (although for different reasons). For to turn matter, as the *Metaphysical Foundations of Natural Science* attempts to, solely into the product of attractive and repulsive forces, would have satisfied naturalistic demands on the first *Critique* without sacrificing transcendentalism. According to Kielmeyer, however,

> Kant neither achieved this, and nor, although he ought to, would he want to; the proof is still wanting that all qualititative differences in matter are simply and immediately differences in the quantitative relations between the attractive and repulsive forces. I would very much like to see this proof undertaken and the qualities of matter explained from these two forces without the intervention of a *tertium*, whether this be God, atoms, or some third force.[78]

---

77. Kielmeyer, *Natur und Kraft*, op. cit., 243.

78. Ibid., 245.

So Kielmeyer demands that the powers hypothesis become an objective ontology. What we are left with now, however, are two accounts of transcendental naturalism: in one, the necessary indeterminacy of being is maintained at the cost of anything other than the subjective determination of actuality; in the other, forces supply a unified and speculative ontogenetic account of the material of knowledge, or objectivity. However, to complete this as an account of transcendental naturalism, an additional element must be added to the powers thesis: namely, the ontological thesis regarding the necessary indeterminacy – and therefore determinability – of being. It is with this in mind that we turn finally to the Cuverian Antinomy.

The Cuverian Antinomy is also Schelling's, and concerns priority and posteriority in relations of determination. Where Cuvier asks whether external nature can be deduced according to principles of mind prior to experience, Schelling asserts that being precedes thinking and not the converse. Since the implicit antinomic contrary in Cuvier's question raises precisely this prospect, we will restate the substance of Schelling's account of it:

THESIS	**ANTITHESIS**
Nature precedes the thinking it spawns	Thinking precedes the Nature it thinks

A transcendental naturalism based on powers may be held to supplant the problem of logical and real priority with that of reciprocity – powers are reciprocally, rather than mechanically or efficiently, determined. Since, however, reciprocity is simply a time-cancelling version of Husserl's co-natality thesis, this strand of transcendental naturalism is clearly dogmatic, in that it asserts a perfected equilibrium or static eternity of forces against the time-based antithesis of that view, as stated in the above antinomy.

If being is necessarily indeterminate, then this indeterminacy must precede its determination, since the converse would entail that being is determinate in advance of its determination, thus defeating the transcendental gambit from the outset. From this, once Kielmeyer's Kant-derived powers ontology is added to it, it follows *not* that being is inert and only acted upon by powers-possessors – since this would amount to a dogmatic reversion to things in themselves – but rather, that being itself is determinability in accordance with powers. It is this, then, that gives Schelling his conviction concerning the priority of being over thinking, and Cuvier his scepticism concerning the priority of thinking over nature: Being is therefore potentiality for determinate being, *Seynkönnen*, rather than the object over which transcendental subjects struggle.

The Schelling-Cuvier antinomy thus results, its transcendental condition-giving notwithstanding, in a dogmatic naturalism premised on the multiple determinability of being. Finally, therefore, transcendental naturalism is either a dogmatic naturalism of the Cuvier-Schelling-Kielmeyer type – that is, simply naturalism – or it is not a naturalism at all, like those of Fichte, Heidegger and Husserl. Copernicanism does not eliminate dogmatism, but continues it in new forms – a dogmatism of appearance as opposed to that of essence, as has been recently made crystal clear by Béatrice Longuenesse:

> It is a fact that we live in a world of things. Still, we must understand that these things are our fact, our doing – not in the sense that a philosophy of praxis would give to this statement [...] but in the sense of a metaphysical account of the world as constituted by a process of thinking.[79]

Just as this dogmatism of appearances resulted from Kant's experiment in thought, it remains true of transcendentalism now, and prompts a challenge to those who pursue transcendental philosophy – to demonstrate that theirs is not simply a dogmatic anti-naturalism.

In conclusion, the ontology of powers, with its modal determinations (necessity, contingency, possibility, actuality), can only be regarded as a reducibly metaphysical problem if the physical dimensions of its actuality are ignored. Field ontology entered physics and philosophy at the same time, although its philosophical pedigree is perhaps longer, stretching back at least to Plato's *Sophist* and the topics and interlocutors addressed therein. Accordingly, I will conclude by drawing out some implications of powers ontologies.

Firstly, powers necessarily involve modal concepts. Against Hegel's denial that the Categories of Modality determine anything objective, objectality is nothing other than a set of potentials for actualisation, as Plato insisted. Powers make contingency into an ontology, a metaphysics and a physics.

Secondly, and again emphasising contingency, powers necessarily involve time determination, not as the transcendental form of inner sense, but, as Johann Heinrich Lambert noted, as determining change: 'If changes are real, then time is real [...]. If time is unreal, then no change can be real'.[80] Of course, this does not mean that the *nature* of time is given in advance as linear, as again physicists remind us.

---

[79] Béatrice Longuenesse, *Hegel's Critique of Metaphysics* (Cambridge: Cambridge University Press, 2007), 6.

Thirdly, powers do constitute a dogmatically assertible transcendental field insofar as they are both necessary to determination and in and of themselves indeterminate.

Fourthly and finally, the prospects for dogmatism are raised wherever the certainties of transcendental reflection are revealed not as another species of reason, but rather as dogmatism parochialised:

Being is necessarily indeterminate if actuality is determinable.

Or, in practical terms:

The necessity of contingency is necessary for the determinability of the actual.

A Throw of the Quantum Dice Will Never Abolish the Copernican Revolution[1]

Gabriel Catren

Illustrations by Cristian Turdera

I. THE PTOLEMAIC REDUCTION OF QUANTUM MECHANICS

One of Kant's seminal contributions to modern science is the injunction according to which the Copernican reflection on the spatiotemporal localisation of the subject of science has to be radicalised into an inquiry regarding its transcendental localisation. If the Copernican revolution allowed the development of a rigorous scientific astronomy delivered of the limits imposed by the contingent localisation of the earth, Kant's critique opens up for the first time the possibility of performing a transcendental deanthropomorphisation of science. Instead of imposing juridical limits on science, such a transcendental self-consciousness should allow a progressive emancipation of the scientific comprehension of nature from the limitations imposed by the a priori structures of scientific knowledge (such as human physiology, categories of human understanding, scales accessible to human experience, technological possibilities, imaginary and ideological representations, limitations imposed by the anthropic principle, particular linguistic structures, sociological, political and economical preconditions of research, and so on).

---

[1] I would like to thank Damian Veal for his insightful criticisms and comments on a first draft of the manuscript. Of course, I take sole responsibility for the final result.

Alas, instead of exponentiating to a transcendental power the projective dehumanisation of science, most proponents of the critical philosophy instead attempted to stitch up the narcissistic wound opened by the Copernican revolution. Even Kant, far from pushing the transcendental revolution to its ultimate, inhuman denouement, instead used his critique to demonstrate that science would never be able to sublate its humanity. In this way, the required transcendental reflection on the preconditions of scientific experience did not lead to the announced transcendental Copernican revolution. On the contrary, the ultimate sense of the Copernican revolution was, as Meillassoux clearly shows in *After Finitude*,[2] completely distorted. A narcissistic reaction aims to counteract the Copernican decentring of the planet earth – and tries to heal what Freud called the 'cosmological humiliation'– by re-situating human existence on a transcendental 'unmoving *Ur*-earth' (Husserl). In the last instance, it does not matter whether humanity dwells on an orbiting earth; the transcendental ego is the ultimate centred source of the objective consistency that science naïvely believes itself to discover in nature.

---

[2] See Chapter Five, 'Ptolemy's Revenge', of Q. Meillassoux, *After Finitude: An Essay on the Necessity of Contingency*, trans. R. Brassier (London: Continuum, 2008).

In particular, quantum mechanics is a privileged target of what Meillassoux has notably called the transcendental 'Ptolemaic counter-revolution'. Indeed, many interpretations of quantum mechanics could be translated – to differing extents – in transcendental terms. In what follows, we will use the term 'transcendental' to characterise any interpretation according to which quantum mechanics can be considered a scientific formalisation of certain impassable limits to the knowledge of physical nature. We could say that a transcendental interpretation of quantum mechanics states that the conditions of possibility of scientific experience restrict the amount of accessible information that can be predicted of (or extracted from) physical systems.[3] This transcendental interpretative framework could thus be summarised in the following terms:

> [...] it now proves quite easy to justify transcendentally a large part of the structure of Quantum Mechanics. One can for instance derive a crucial part of the quantum formalism from assumptions about the limits of accessible experimental information; or from assumptions about contextuality of phenomena [...] This means that one is no longer compelled to understand quantum theories as a representation of the 'external', 'independent' world, with all the strangeness and paradoxes that are associated with such a representation. Rather, quantum theories can very naturally be understood

---

[3] The forthcoming book *Constituting Objectivity: Transcendental Approaches of Modern Physics,* M. Bitbol, P. Kerszberg and J. Petitot (eds) The Western Ontario Series in the Philosophy of Science, Vol. 74 (Berlin: Springer Verlag, forthcoming February 2009) is entirely devoted to the relationship between transcendental philosophy and modern physics. Some of the most interesting and far-reaching transcendental analysis of the quantum formalism can be found in the works of S. Y. Auyang, M. Bitbol, E. Cassirer, B. Falkenburg, G. Hermann and P. Mittelstaedt. We address the reader to the aforementioned work for all the relevant references.

as expressing the constraints and bounds of (experimental) knowledge. This is very much in the spirit of Kant, if not in the letter of his original texts.[4]

In classical mechanics, the exact position and the exact momentum (roughly speaking, the velocity) of a particle can be simultaneously predicted for all times from a given set of initial conditions. In quantum mechanics, on the contrary, we cannot predict the momentum of a particle characterised by a well-defined position (and vice versa). More generally, Heisenberg's uncertainty principle states that certain pairs of variables can be simultaneously predicted only up to some inversely-correlated uncertainties. It is therefore tempting to try to localise the transcendental a priori structures (instrumental, pragmatic, cognitive, linguistic, etc.) that are at the origin of this supposed limitation. According to this 'Kantian' strategy, quantum mechanics seems to show that it is impossible to go through the 'transcendental' looking-glass towards a hypothetical 'nature-in-itself' inhabited by systems with intrinsic properties. Rather, quantum mechanics seems to provide a mathematical account of the correlations between the 'observed' systems and their (not necessarily human) 'observers'.[5]

---

[4] M. Bitbol et al., *Introduction to Constituting Objectivity: Transcendental Approaches of Modern Physics*, op.cit, 17-18.

[5] It is worth remarking that the thesis according to which quantum mechanics only describes correlations between physical systems does not necessarily entail that there exist impassable limits to the knowledge of nature. For example, the so-called 'relational' interpretations of quantum mechanics maintain that the notion of an isolated system with 'absolute' properties is meaningless. We could say that this strategy amounts – in a Hegelian style – to avoiding anthropomorphic interpretations of the quantum 'limitations' by ontologizing the correlations and doing away with any phantomatic 'thing-in-itself'. Hence, relational quantum mechanics cannot be considered a transcendental interpretation of the theory. These relational interpretations could be summarised by means of the following claims:

In this way, physicists seem forced to accept that they cannot abstract from the *constitutive* role that their measuring instruments play in experimental inquiry. This means that quantum systems seem to be inherently *contextual*, that is to say we cannot separate their properties from the experimental contexts that constitute them as systems. The quantum realm that underlies our everyday object-oriented macroscopic experience is a kind of uncanny domain peopled with weird, shadowy entities that assume definite properties only when they are observed, that 'decide' to behave like waves or particles depending on the experimental setup, and so on. In Kantian terms, we could say that quantum systems seem to conform to our faculty of experimental intuition. If classical mechanics is supposed to rely on a classical ontology of observer-independent physical objects endowed with intrinsic objective properties, quantum formalism seems to forbid any ontological extrapolation in terms of decontextualised physical objects. Employing Popper's characterisation of the so-called Copenhagen interpretation of quantum mechanics, we might say 'that quantum mechanics does not represent [physical systems], but rather our knowledge, our observations, or our consciousness, of [physical systems]'.[6] Instead of pushing our comprehension of nature's rational structure further than

---

'Properties of quantum systems have no absolute meaning. Rather, they must be always characterised with respect to other physical systems. Correlations between the properties of quantum systems are more basic that the properties themselves.' C. Rovelli, 'Relational quantum mechanics', *International Journal of Theoretical Physics* 35, 1996, 1675. See also F. Laudisa & C. Rovelli, 'Relational Quantum Mechanics', in Edward N. Zalta (ed.) *The Stanford Encyclopedia of Philosophy* (Fall 2008 Edition), at http://plato.stanford.edu/archives/fall2008/entries/qmrelational/.

[6] K. Popper, *Quantum Theory and the Schism in Physics* (Cambridge: Unwin Hyman, 1982), 35. (Popper writes of 'particles' rather than 'physical systems').

classical mechanics, quantum physics forces us to withdraw from noumenal nature and to place ourselves at the centre of a transcendentally-constituted experience. In doing so, quantum mechanics, far from positively extending physical knowledge, only allows us to recognise the transcendental illusions of classical mechanics and to set out the juridical limits of the precritical dream.

In this article, we will argue that in order to construct a satisfactory interpretation of the quantum formalism it might be necessary to advocate what we could call a 'precritical realism', that is to say, to put aside any kind of transcendental considerations. Far from denying the importance and the necessity of a transcendental reflection – and of the consequent transcendental deanthropomorphisation of scientific knowledge – we only mean to suggest that the theoretical scope of quantum mechanics might be strictly physical rather than transcendental. If this were indeed the case, then we would have to accept that, from the point of view of a transcendental critique of scientific knowledge, quantum mechanics is just as 'precritical' as classical mechanics.

When confronted with the paradoxes of quantum mechanics, Einstein adopted what we could call a 'naïve', 'precritical' attitude. Indeed, he was not willing to accept 'transcendental' limits to physical knowledge; he continued to long for a physical theory capable of describing physical reality in *realistic* (i.e. observer-independent) and *complete* terms. Regarding the supposed limitations imposed by Heisenberg's uncertainty principle, Einstein expected the advance of physics to lead to a more complete theory that would describe *all* the 'elements of physical reality' – that is, both the position and the momentum of quantum systems.[7] In this article we claim that Einstein was completely right in demanding, in spite of the critical attempts to interpret quantum mechanics in a 'transcendental' framework, that a physical theory has to be 'realistic' and 'complete'. According to the position that we will advocate, he only failed in not recognizing that quantum mechanics itself provides, *unlike classical mechanics*, a 'realistic' and 'complete' description of physical reality. The main objective of this article is to support this last claim in purely conceptual terms.[8]

II. SPECULATIVE PHYSICS

Before presenting such a 'precritical' interpretation of the quantum formalism, we want to make some remarks concerning the motivations and the methodology of this ongoing project. We could say that the discussion that we shall propose belongs to a particular mode of physical thinking that we shall call, in the wake of Schelling, *speculative physics*. We shall now give a succinct description of what we mean by this term.

In general, the substitution of one physical theory by another one is not a consequence of the mathematical inconsistency of the former. In particular, both classical and quantum mechanics are mathematically-consistent theories.

---

[7] A. Einstein, B. Podolsky and N. Rosen, 'Can Quantum-Mechanical Description of Physical Reality be Considered Complete?', *Phys. Rev.* 47, 1935, 777-80.

[8] More technical justifications of the proposed arguments, as well as an extended bibliography, can be found in the following articles: G. Catren, 'On Classical and Quantum Objectivity', *Foundations of Physics* Vol. 38, No. 5, 2008, 470-87 (available from http://philsci-archive.pitt.edu/archive/00004298/); G. Catren, 'Can Classical Description of Physical Reality be Considered Complete?', in M. Bitbol, P. Kerszberg and J. Petitot (eds.), *Constituting Objectivity: Transcendental Approaches of Modern Physics*, op. cit. (available from http://philsciarchive.pitt.edu/archive/00004295/).

Hence, mathematical constraints do not seem to suffice for explaining the a priori necessity of physical theories. The heuristic postulate of speculative physics asserts that physical theories are endowed with a rational necessity that stems *neither* from their mathematical consistency, *nor* from the transcendental preconditions of human experience. If physics formulates laws that describe the consistency of natural phenomena, speculative physics aims to understand why *these* particular laws or theories, instead of others, describe nature. In other words, speculative physics aims to raise what seem to be empirical (or contingent) laws of nature to the status of rational necessities. In order to do so, speculative physics has to establish demarcation lines between mathematical necessity, transcendental structures, and other kinds of a priori principles. Using Kantian rhetoric, we could say that we apply the term 'speculative' to all knowledge that is not so much occupied with discovering the laws of physical nature as with ascertaining their a priori (neither mathematical nor transcendental) rational necessity. In other words, speculative physics aims to reduce as far as possible the contingency of natural laws, that is, to deduce their empirical validity from a priori principles. For the fact that empirical experience provides very important clues for the seeking of more satisfactory physical theories, for their effective construction and for their a posteriori (provisional) corroboration, does not necessarily mean that it is impossible to unveil retrospectively their own rational necessity. As Schelling writes, 'it is *not, therefore*, that WE KNOW Nature as a priori, but Nature *IS* a priori [...] But if Nature *is* a priori, then it must be possible to recognise it as something that is a priori [...]'.[9] Such a recognition is the main task of speculative physics. Even if the hypothetical limits of human understanding prevented scientists from absolving physics of its experimental basis in empirical experience, this fact cannot be used as a proof of the *essentially* contingent character of the laws of nature. As Hegel clearly states, 'the course of a science's origin and the preliminaries of its construction are one thing, while the science itself is another. In the latter, the former can no longer appear as the foundation of the science; here, the foundation must be the necessity of the Notion.'[10] We can thus state that speculative physics tries to consider the laws of nature in their 'own immanent necessity in accordance with the self-determination of the Notion.'[11] If physics depends upon empirical data, speculative physics aims to unveil the inherent rational necessity of physical theories independently of any experimental justification or corroboration. In this way, speculative physics challenges the unquestioned presupposition according to which physics is *de jure* an empirical science. We could thus say about physical theories what Schelling says about the 'judgements of experience', namely that these theories '[...] become a priori [...] when we become conscious of them as necessary [...]'.[12] The very possibility of ascertaining the rational necessity of physical theories stems from the postulate according to which '[...] the distinction between a priori and a posteriori judgements is not at all, as many people may have imagined, one originally cleaving to the judgements themselves, but is a distinction made solely with respect to our knowing, and the kind of our knowledge of these judgements, so that every judgement which is merely historical for me – i.e., a judgement of experience – becomes, notwithstanding, an a priori principle as soon as I arrive, whether directly or indirectly, at insight into its internal necessity.'[13]

[11] Ibid., 6.

[12] Schelling, op.cit., 198-9.

The very terms of this project go against the main claim of Meillassoux's *After Finitude*, namely that it is possible to demonstrate the necessary contingency of physical laws. The essential point for the present discussion is that Meillassoux simply disqualifies the possibility of *deducing* the laws of nature. Following Hume, he assumes that ('unless we are Hegel')[14] we are unable to discover such a necessity. Consequently, he says, we can only *describe* the *contingent* structural order that we *empirically* find in nature. To justify these claims, Meillassoux identifies natural laws with inductive inferences, obviating in this way the fact that inductive reasoning does not play any role in contemporary physics. The lack of any logical justification for inductive inferences leads Meillassoux to conclude that the nomological constancy of nature is not grounded on any a priori necessity. We might say that Meillassoux elicits the implicit 'metaphysical' content of the standard thesis according to which the undecidability between two mathematically consistent theories can only be settled by appealing to empirical experience. The physicist's job would be to choose the most accurate mathematical model for describing a completely contingent empirical order. If for Rutherford 'all science is either physics or stamp collecting', according to Meillassoux we must accept that even physics is mere (mathematised) stamp collecting.

---

[13] Ibid., 198-9.

[14] Q. Meillassoux (with R. Brassier, I. H. Grant and G. Harman), 'Speculative Realism' in R. Mackay (ed.), **COLLAPSE III** (Falmouth: Urbanomic, 2007), 441.

The only argument that Meillassoux seems to give, besides the simplistic reduction of physics to inductive inferences, is that the project of demonstrating the necessity of natural laws supposes an infinite regress of reasons that could only be interrupted by a 'metaphysical ' first cause capable of positing itself in virtue of its mere notion (an 'ontological argument'). In other words, since the project of (absolute) knowledge seems to be either an 'infinite task' (Husserl) or a 'metaphysical ' project (Hegel), we must accept the absolute validity of the 'abstract negation' according to which it is simply not possible to understand why nature is regulated by certain laws instead of others. With regard to this second argument, it is worth noting that Meillassoux seems to conflate the formal ontology of possible worlds with the problem of understanding the hypothetical necessity (or contingency) of existence, that is to say of the effective *givenness* of ontic reality. But even if we rejected the possibility of an ontological argument capable of deducing existence from the concept, this would not prevent us from tackling the problem of understanding the rational necessity of physical theories. We could say that a physical theory provides a particular provisional solution to a certain problem. For instance, quantum mechanics is, as we shall argue below, the best solution that we have at the moment to the problem of explaining the objective consistency of nature. In order to understand the rational necessity of quantum mechanics, speculative physics must (among other things) evaluate the unicity of this solution. Are there other possible solutions to the problem of constructing a theory of generic physical objects besides quantum mechanics? To what extent could the physics of a possible world differ from the physics of our world? Even if we could prove the impossibility of an ontological argument, this 'no-go theorem' would not entail that we cannot analyse in rational terms the physical constraints of a possible world and their range of variability. It is also worth remarking that the project of understanding the rational necessity of physical theories defines local problems of scientific knowledge like any other. The answers that speculative physics can provide are of course – as is always the case in science – conditional and partial answers that will evolve within the rhythm of physics and mathematics. It is difficult, then, to understand why the supposed impossibility of providing a satisfactory rational global model for the 'topology' of absolute knowledge (an infinite regress of reasons, an 'axiomatic' well-founded system, a Hegelian suspended circle, etc.) would imply the futility of such a local project.

Far from providing stronger arguments for showing that natural laws do *in fact* lack any rational necessity, Meillassoux's addresses his efforts to the demonstration that this supposed contingency cannot be an epistemological limitation of human understanding, but must rather be an absolute principle. Therefore, Meillassoux's attempt to demonstrate the *absolute* (i.e. non-epistemological) contingency of physical laws relies on the unquestioned presupposition that *in fact* it is not possible to discover any rational necessity. Even if we can decide legitimately to explore the consequences of the *hypothesis* according to which the laws of nature lack any rational a priori necessity, we cannot pretend that we are rationally forced to accept the validity of such an hypothesis, nor that the principle of reason must be abandoned.

Moreover, even if it were true that we are unable to determine the rational necessity of natural laws, this supposed *empirical* fact could not be used as proof of their absolute contingency. If we assume that we cannot discover any rational necessity in physical laws, we have to decide whether this incapability results from the limits of human understanding or from the fact that physical laws are intrinsically contingent. We shall call this alternative Dilemma I. Nevertheless, instead of addressing this dilemma, Meillassoux tries to decide whether the contingency of physical laws is a correlate of human thought or rather an absolute contingency. We shall call this alternative Dilemma II. In order to solve this second dilemma, he argues that facticity cannot be consistently considered a correlate of thought. In this way, he concludes that facticity could only be an 'absolute' facticity. However, the crucial step for passing from the pertinent Dilemma I to the fictive Dilemma II is the deliberate confusion between epistemological criticism (according to which we cannot discover any rational necessity in natural laws because we are not clever enough) and ontological idealism (according to which facticity is a correlate of thought). But the hypothetical existence of impassable limits of human understanding cannot be legitimately identified with the thesis according to which 'to be is to be a correlate of human thought'. In short, to say that an ant will never be able to understand general relativity does not mean that one believes that nature is nothing but a correlate of the ant's 'thought'. If we restore this essential difference between Kant and Berkeley, the inference that leads from our alleged inability to discover any natural necessity to the absolutisation of facticity remains groundless. Indeed, the first step for pushing further the Copernican deanthropomorphisation of science is to reduce the narcissistic illusion of converting a conjectural limit into an absolute principle. We must avoid at all costs being like a congenitally deaf person trying to demonstrate the absolute impossibility of music. Indeed, Hume and Kant were perfectly right to reject any kind of ontological extrapolation of epistemological limitations. Just as Hegel, in turn, was right to deny the unavoidable character of these limitations.

To summarise, we can say that Meillassoux's 'proof' ('for it is indeed a proof', as Badiou tells us)[15] begins with an unquestioned (and probably false) presupposition (namely, that physics cannot discover any rational necessity in physical laws), and proceeds by means of an illegitimate 'deductive' inference (namely, that of absolutising a supposed limitation). Far from defending science from the Ptolemaic counter-revolution that Meillassoux describes so admirably, this narcissistic absolutisation of an inexistent limitation bolsters a certain form of philosophical contempt for scientific rationality. Indeed, the shift from a gnoseological statement to a speculative one only serves to absolutise the critical reduction of science. Meillassoux rehearses a paradigmatic gesture of 'Kantian' critique, namely that of 'proving', in purely philosophical terms, what physicists will never be able to do – in this case, understand the rational necessity (or the corresponding ranges of variability) of their own theories. Moreover, this is consistently done without any consideration of physics itself – after all, why should the philosopher consider in detail scientific (ontical) descriptions lacking any rational necessity if he can produce philosophical (ontological) demonstrations? Why would he analyse in accurate terms that of which he speaks – namely, physical theories – if he knows in advance that physics is only a collection of contingent laws that can change without any reason? Why should he try to understand the rational structure of particular physical theories, if the latter will surely be superseded by other theories, as has always been the case in the history of science … ?

---

[15] A. Badiou, 'Preface' in Q. Meillassoux, *After Finitude*, op. cit., vii.

It is worth noting that, if speculative physics aims to force as far as possible the conversion of physics into an a priori discipline, the progressive comprehension of the rational necessity of natural laws is already a constitutive part of theoretical physics itself. For example, we could say that, at least to a certain extent, Einstein 'deduced' general relativity by means of purely theoretical reasoning lacking any empirical motivation. Moreover, we can now provide a priori arguments that show why general relativity is a more satisfactory theory than the Newtonian theory of gravity. Indeed, we could say that one of the great lessons of general relativity is that it is necessary to absolve physics from the presupposition of any kind of metaphysical or transcendental (back)ground. More precisely, general relativity permitted scientists to free the description of gravitational phenomena from some of the geometrical 'absolute objects' (as Anderson calls them) presupposed by the Newtonian theory.[16] The replacement of a *metaphysical 'God-given' ground* – the spatiotemporal background – by new physical degrees of freedom – the gravitational field – produced what we could call a *suspended (cor)relational nature*. As a result, the relativity of motion could be generalised beyond uniform motion: Accelerated motion, far from being defined with respect to a presupposed fixed geometrical stage-set, is 'relative' to the gravitational field (which defines the geodesics of space-time). Hence, the dynamics of the resulting extended set of interacting degrees of freedom is relative to nothing but itself. In this sense, general relativity established from within physics a 'speculative' disjunction between the correlational *absolute* and the metaphysical (or transcendental) *ground*. In Hegelian terms, we could say that the absolute absolves itself from any ultimate ground, that is to say from any last unmoving instance subtracted from the immanent mediation conveyed by physical interactions. It is then necessary to establish a sheer distinction between the *principle of reason* and the *principle of the ground* (*Der Satz vom Grund*). The history of physics clearly shows that the principle of reason – that is to say, the practical imperative of pushing the rational comprehension of the real as far as possible – requires us to abandon the metaphysical principle of the ground. Science does not progress by trying to found itself on a last self-posited metaphysical or transcendental reason, but rather by trying to absolve itself from any kind of presupposed background. At the antipodes of Meillassoux's stance concerning the metaphysical scope of 'correlationism', we can say that general relativity taught us that an absolution with respect to any metaphysical background whatsoever requires us to understand nature in (non-anthropomorphic) correlational terms.

---

[16] See J. L. Anderson, *Principles of Relativity Physics* (New York: Academic Press Inc., 1967); M. Friedman, *Foundations of Space-Time Theories. Relativistic Physics and Philosophy of Science* (Princeton: Princeton University Press, 1983); C. Rovelli, *Quantum Gravity* (Cambridge: Cambridge University Press, 2004); and G. Catren, 'Geometric foundations of classical Yang-Mills Theory', *Studies in History and Philosophy of Modern Physics* 39, 2008, 511-31.

To summarise, let us admit that we now understand the intrinsic theoretical limitations of the Newtonian theory of gravity for explaining gravitational phenomena. This means that it is not contingent that nature is better described by general relativity than by Newtonian mechanics, nor that general relativity has the particular formal structure that it has. This comprehension of the rational necessity of general relativity is not incompatible with the fact that this theory will surely be superseded by a more satisfactory one, in this case a quantum theory of gravity. Such a substitution will probably not be a 'scientific revolution' that will condemn general relativity to death, but rather a kind of dialectical overcoming that will deepen the main lesson of general relativity; namely, that physics has to absolve itself from any kind of metaphysically or transcendentally presupposed background. More generally, we could say that the main task of speculative physics is to elicit the conceptual continuity and the rational necessity that bridges the historical discontinuities opened up by so-called 'scientific revolutions'.

If Meillassoux is right in asserting that the attempt to demonstrate the necessity of laws of nature is basically the Hegelian project, he presupposes dogmatically that such a project cannot be legitimately reactivated. Hegel's (as well as Schelling's) philosophy of nature depends on a *heuristic* (not dogmatic) raising of the principle of reason to a higher power: If physics explains the nomological consistency of nature, we should try to explain in purely rational terms why physical laws have the particular form they have. Such a task cannot be effectively developed by trying to demonstrate general statements about the global validity of the principle of reason, but only by trying to apply it locally to particular scientific theories. If in the end such a project could not be effectively accomplished, it would at least permit us to localise and characterise in rigorous and precise terms the corresponding kernels of irreducible facticity. Hence, we could say that speculative physics aims to discriminate between what is *essentially* contingent and what stems from an a priori necessity. In other words, the speculative conversion of empirical determinations into a priori principles should permit us to identify what is essentially empirical. Indeed, the effective possible obstructions to the principle of reason can only be identified by remaining faithful to this principle as far as possible. As is usually the case in mathematics, the most interesting theoretical configurations emerge as obstacles to the realisation of a certain programme. In other words, it is necessary to be programmatically ambitious in order to fail in a productive way. On the contrary, the a priori general 'proof' that the program is condemned to failure is simply unfruitful. In our particular case, this means that we shouldn't give up on our desire to understand the a priori principles that guarantee the rational consistency of nature. Paraphrasing Badiou, we could adopt the following methodological prescription: 'Méfions-nous des gens trop pressés de consentir [à l'irraison]. [...] J'aime qu'on abdique [le principe de raison] seulement contraint et forcé.'[17]

The proposed definition of speculative physics entails the following methodological consequence: in order to understand the rational necessity of a physical theory it is necessary to comprehend 1) the inherent theoretical deadlock of the preceding theory and 2) how the new theory bypasses this impasse. In other words, the *speculative deduction* of a physical theory aims to identify what we could call its *theoretical surplus value*. This means that speculative physics does not try to demonstrate the *unconditional* rational necessity of a physical theory, but rather to localise its *differential* theoretical superiority. In particular, even if – undoubtedly – quantum mechanics is not the final satisfactory formulation of mechanics, it should be possible to understand *in purely conceptual terms* why it is a more satisfactory theory than classical mechanics. This apparently banal prescription has important consequences. In particular, it challenges the prevailing idea that the difficulties in understanding quantum mechanics contrast with our satisfactory comprehension of classical mechanics. Indeed, our definition of speculative physics implies that our lack of a conceptual understanding of quantum mechanics is a direct consequence of our unsatisfactory comprehension of classical mechanics. More precisely, we have not yet understood precisely what internal theoretical deadlocks in classical mechanics make its quantum sublation necessary. In other words, we do not understand why it is not a contingent empirical fact that the objective consistency of nature is better formalised by quantum mechanics than by classical mechanics. Hence, in order to comprehend the rational necessity of quantum mechanics we must go back to classical mechanics and try to identify its theoretical flaws. According to this perspective, quantum mechanics, instead of inaugurating a radically new non-classical 'paradigm', should be understood as deepening a programme initiated by classical mechanics. In other words, the astonishing success of quantum mechanics shows retrospectively that Newton, Galileo and Kepler were in fact on the right path.

---

[17] In the original quotation Badiou writes 'mi-dit ' (literally 'half-said', but the sense is 'half-hearted' or 'half-measure') and 'Tout' ('Whole') instead of 'irraison' and 'principe de raison' respectively. See A. Badiou, *Théorie du sujet*, (Paris: Editions du Seuil, 1982), 138. ('Let us be wary of those too keen to consent [to 'unreason']. I would rather one abjure [the principle of reason] only when constrained and forced to do so'. *Theory of the Subject*, trans. B. Bosteels [London: Continuum, forthcoming 2009]. Translation modified).

This is the effective methodological prescription we have followed in arriving at the conclusions described below. That is to say, we tried to localise the intrinsic deadlocks of classical mechanics and the corresponding theoretical surplus value of quantum mechanics. Very briefly, in classical mechanics there exists a certain correspondence between each physical quantity of physical systems (such as the position, the momentum or the energy) and the so-called *classical operators*.[18] The important point is that this classical correspondence between physical quantities and classical operators is not entirely satisfactory because it does not associate *distinct* physical quantities with distinct classical operators (i.e. the classical correspondence is not an isomorphism).[19] It is possible to show that the mathematical formalism of quantum mechanics emerges when one forces this isomorphism. To do so, it is necessary to substitute quantum operators for the classical operators.[20] Hence, the heuristic questions of speculative physics, in the case of quantum mechanics, are the following: Why do operators play such a fundamental role in mechanics? What is the conceptual content of the correspondence between physical quantities and operators? And why should this correspondence be isomorphic?

---

[18] Roughly speaking, an operator is a mathematical entity that generates transformations of other mathematical entities. For example, a derivative is a mathematical operator that transforms functions into other functions.

In order to answer these questions we have to take into account that physics could be defined as a *theory of objects*. Such a theory consists of two parts. In the first place, physics depends on a general formalism, called *mechanics*, for treating any kind of physical objects, that is to say for studying their properties, their symmetries, their temporal evolution, and so on. Secondly, there are different particular kinds of objects (particles, fields, molecules, waves, astrophysical systems, etc.) that can be treated by means of this general formalism. The different branches of physics result from the application of the general formalism to the study of these different particular systems. If mechanics is a general formalism that can be used to study *any* kind of physical system, it could be tempting to define mechanics as a formal ontology of generic physical objects. By *formal ontology* we mean the study of generic determinations that do not depend on the particular properties of any particular (kind of) object. In Kantian terms, we could say that mechanics is a formalisation of the structure of the (non-transcendental) generic object = X. The important point is that, contrary to a widespread idea, classical mechanics does not provide a satisfactory definition of physical objects. It is then possible to show that quantum mechanics permits an overcoming of the classical obstacles to the formulation of such a definition. As we shall see, the definition of physical objects depends essentially on the correspondence between physical quantities and operators. Therefore, the complete claim is that quantum mechanics, *unlike classical mechanics*, is a consistent formal ontology of generic physical objects. Indeed, and as we shall see, quantum mechanics seems to provide a possible physical solution to a transcendental problem, namely the problem of understanding the constitution of physical objects by means of a synthesis of the manifold of sensible (or experimental) intuition. As opposed to Kant's or Husserl's solution, quantum mechanics shows that the intrinsic consistency of physical objects does not require any transcendental – i.e. (inter) subjective – constitution. As we shall see, this solution pushes the Copernican deanthropomorphisation of physics to a further limit: rather than the transcendental subject, it is the object itself that generates the synthetic operations which unify the phenomenological manifold of its aspects or profiles. In Kantian terms, one might say that quantum mechanics demonstrates how to make physics conform to the quantum nature of self-constituted objects, and not the objects to our (all too human) faculty of classical intuition.

---

[19] In technical terms, physical quantities are given by functions on the phase space, whereas classical operators are given by so-called Hamiltonian vector fields: See R. Abraham and J. E. Marsden, *Foundations of Mechanics*, Second Ed., (Cambridge: Addison-Wesley Publishing Company, 1978).

[20] It is worth noting that this characterisation of the relationship between classical and quantum mechanics is not the usual one. In fact the proposed interpretation of quantum mechanics stems from an analysis of the so-called geometric quantisation formalism, due mainly to the seminal works of J.-M. Souriau and B. Kostant in the early seventies (see J.-M. Souriau, *Structure of Dynamical Systems. A Symplectic View of Physics* [Cambridge: Birkhäuser Boston, 1997] and J.-L. Brylinski, *Loop Spaces, Characteristic Classes and Geometric Quantisation*, *Progr. Math.* 107 [Boston: Birkhäuser Boston Inc., 1993]).

III. PHENOMENOLOGY OF A QUANTUM ELEPHANT

Physical experience is not a chaotic swarm of disconnected empirical data. As Whitehead cleverly observed: 'Sometimes we see an elephant, and sometimes we do not'.[21] In other words, physical reality decomposes itself in different objective configurations that can be identified and recognised. We should add that properly speaking we can only see particular phases, aspects or profiles of the elephant. As Lacan says, 'l'être se présente, se présente toujours, de par-être'.[22] By turning the elephant around an axis (or, equivalently, by moving around the elephant ourselves) we can observe *different* phases of the *same* elephant. This means that there is a defining kernel (that we could call the elephant's *quiddity*) that remains invariant through the modifications of its modes of phenomenological presentation. We can thus define an object as a physical configuration characterised by a certain set of *objective properties* that allow virtual observers to recognise the object in spite of the variations of its phases. As Badiou says: '[...] par «objet» il faut entendre ce qui compte pour un dans l'apparaître, ou ce qui autorise à parler de cet être-là comme étant inflexiblement «lui-même».'[23] This means that the objective properties that define the object cannot change under the transformations that permit observation of its different phases (for instance, turning the elephant around an axis). Henceforth we shall call such transformations *phase transformations* of the object. Hence, we can assert that objective properties must be *invariant* under phase transformations. We can thus redefine an object as a set of invariant objective properties that manifests itself through a phenomenological multiplicity of phases. This means that there is no entity without identity (Quine), nor without different phases (Husserl). In Frege's terms, we could say that the same reference (*Bedeutung*) can have different senses (*Sinn*), that is to say different modes of presentation. For example, the morning star and the evening star are nothing but different modes of presentation of the same object.

---

[21] A. N. Whitehead, *Process and Reality* (New York: The Free Press, 1978), 4.

[22] J. Lacan, *Le Séminaire*, livre XX (Paris: Editions du Seuil, 1975), 44 ('being presents itself, always presents itself, by para-being.' J. Lacan, J.-A. Miller (ed.), *On Feminine Sexuality, The Limits of Love and Knowledge, 1972-3*, trans. B. Fink [New York: Norton, 1998], 45. Note that the English translation does not preserve Lacan's play on words 'par-être'/'paraître' ['para-being'/'to appear']).

In this way, the manifold of sensible intuition decomposes itself in sheaves of aspects orbiting around sets of invariant objective properties. As Kant and Husserl noted, the objective consistency of nature requires an operational function capable of synthesizing the multiplicity of phases of a given object. Therefore, a satisfactory theory of physical objects should be able to explain the relationships between the *invariant objective properties* that define the *quiddity* of the object, the *phenomenological multiplicity of its phases*, and the *synthetic operations* that guarantee its objective unity. According to the transcendental tradition, the unifying synthesis is performed by the subjective faculties. In Husserl's terms, the 'hyletic' multiplicity of sensible intuition becomes a 'noematic' objective unity thanks to the 'noetic' functions of synthesis carried out by the transcendental ego. In other words, the subjective functions of synthesis posit, on the basis of bundles of sense data lacking any intrinsic consistency, the ideal objective unities that compose human experience.

---

[23] A. Badiou, *Logiques des mondes*. (Paris: Seuil, 2006), 205 (' [...] by "object" we must understand that which counts as one within appearing, or that which authorises us to speak of this being-there as inflexibly being "itself"'.', A. Badiou, *Logics of Worlds*, trans. A. Toscano [London/New York: Continuum, forthcoming 2009], 193).

The main task of what we could call a speculative theory of physical objects is to explain the objective consistency of nature without appealing to a transcendental synthesis. As Whitehead says: 'We are concerned only with Nature [...] and not with the synthesis of the knower with the known. [...] Accordingly none of our perplexities as to Nature will be solved by having recourse to the consideration that there is a mind knowing it. Our theme is the coherence of the known [...]'.[24] Our main claim is that, according to quantum mechanics, it is the object itself that generates the synthetic operations that unify its different phases. In other words, we shall transfer the constitutive capabilities from the subject to the object. As we shall see, the utilisation of operators in mechanics is a direct consequence of the necessity of (self-)synthesizing the multiplicity of the object's phases. Hence, operators play a central role in mechanics because mechanics is nothing but a formal theory of generic physical objects, that is to say a theory that explains how the multiple phases of an object are mutually related by means of certain synthetic operations that leave its objective properties invariant. The important point is that a satisfactory interpretation of mechanics as a theory of generic physical objects is only possible within the framework of quantum mechanics. The theoretical surplus value of quantum mechanics relies on the fact that the classical definition of operators does not permit a satisfactory definition of physical objects.

---

[24] A. N. Whitehead, *An Enquiry Concerning the Principles of Natural Knowledge* (New York: Dover, 1919), vii.

We shall now present in conceptual terms the ontology of generic physical objects that can be extracted from the formalism of quantum mechanics. As we said before, an object is a kind of 'projector' (or 'radiator') of phases, aspects or profiles whose essential *quiddity* is given by a persisting kernel of invariant objective properties. The set of invariant objective properties of an object will be called from now on the *eidos* ε of the object. In general, it is possible to perform different kinds of phase transformations in order to observe the multiple phases of an object. Borrowing Husserl's terminology, we could also call the phase transformations 'eidetic variations'. A set of phases connected by means of a given kind of phase transformation (such as, for instance, rotations around a given axis) will be called an *orbit of phases*. In Figure 1, the different lateral phases of the elephant (whose name is Colin) can be observed by rotating Colin around a vertical axis. By definition, these different lateral phases belong to the same orbit of phases. Equivalently, let's suppose that the phenomenological observer Jean-Sol Partre is orbiting around Colin in a plane perpendicular to the vertical axis. By doing so, Jean-Sol Partre will observe the phases of Colin that belong to the orbit of lateral phases.

Phase transformations are 'phantasmatic' acts that do not produce any *objective* effect. Therefore, phase transformations

ξ_{colin}
θ_{colin}

Figure 1. Jean-Sol Partre observes elephant

have to be distinguished from transformations that change the object *objectively*, that is to say that change the object into *another* object. For instance, the transformation that breaks an object into two objects is not a phase transformation of the former. These kinds of transformation will be called *objective transformations*. In this way, there are two kinds of transformations that can be performed on an object, namely the *objective transformations* that objectively transform the object into another object, and the *phase transformations* (or 'eidetic variations') that interchange the different phases of the object without modifying it objectively.

Since phase transformations only interchange the different phases of an object, the objective properties that define the object are necessarily invariant under phase transformations. In Husserl's terms, the object's *eidos* is composed of the invariants under eidetic variations. In order to stress that phase transformations transform the object into itself, they will also be called *automorphisms* of the object. With this terminology, we recover Weyl's well-known characterisation: 'objectivity means invariance with respect to the group of automorphisms.'[25] It is worth stressing that *phase transformations* (that interchange the phases of the object), *eidetic variations* (that permit the definition of the invariant objective *eidos*) and *automorphisms* (that transform the object into itself) are interchangeable terms. These three terms, however, emphasise different aspects of the same notion. The fundamental distinction is the distinction between phase transformations on the one hand and objective transformations on the other.

---

[25] H. Weyl, *Symmetry* (Princeton: Princeton University Press, 1952), 132. An analysis of the relationship between group theory and perception can be found in E. Cassirer, 'The Concept of Group and the Theory of Perception', *Philosophy and Phenomenological Research* Vol. 5, No. 1 (1944), 1-36.

It is now necessary to specify more precisely what we understand by objective properties. To do so, we have to take into account that the characterisation of objective properties as *invariants* under eidetic variations does not suffice for providing a satisfactory definition of objective properties. The problem has been clearly stated by Nozick in the following terms: 'The notion of invariance under transformations cannot (without further supplementation) be a complete criterion of the objectivity of facts, for its application depends upon a selection of *which* transformations something is to be invariant under.'[26] In other words, there is no general prescription for determining which transformations are needed in order to define the invariant objective properties of a physical object. Therefore, the eidetic invariants depend on the election of a certain group of eidetic variations.[27] If we consider too many transformations as eidetic variations, the 'object' will have no eidetic invariants. Every property of the object will be nothing but a phase with no objective value. Hence, the 'object' will be a phenomenological set of phases without any invariant identity. If, on the contrary, we consider too few transformations as eidetic variations, the object will have no phases. This means that every property of the object will be an objective invariant. Hence, the 'object' will be an identity without phases.

---

[26] R. Nozick, 'Invariance and Objectivity', *Proceedings and Addresses of the American Philosophical Association* Vol. 72, No. 2 (1998), 21-48. In Weyl's terms, 'Reality may not always give a clear answer to the question what the actual group of automorphisms is [...]', H. Weyl, op.cit., 132.

[27] Evidently, we cannot solve this problem in a circular way by stating that the automorphisms of an object are the transformations that leave the objective properties invariant.

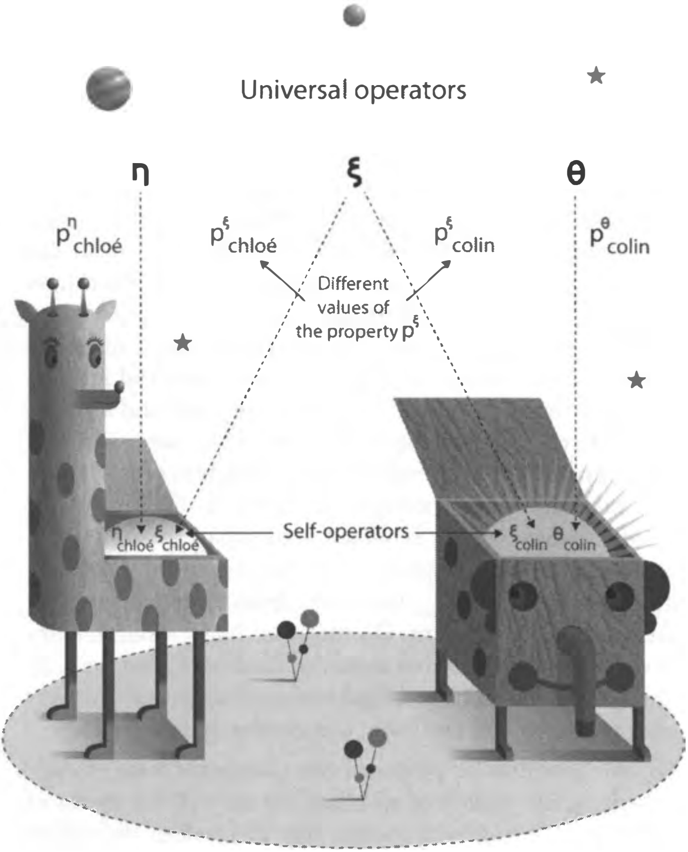
In fact, quantum mechanics provides a very elegant solution to this indetermination. As we shall see, the quantum definition of physical objects furnishes the required 'further supplementation' by stating that the object's automorphisms are induced by the very objective properties of the object. In other words, each objective property defines a particular kind of phase transformation. Hence, not only is an objective property invariant under all of the object's automorphisms; it also induces a particular kind of automorphism. Far from being a circular characterisation, we shall show that Heisenberg's uncertainty principle is a direct consequence of this definition.

In order to formalise this idea, we shall propose a definition of physical objects by means of two fundamental postulates. But first we must introduce some terminology. In Platonic terms, we shall say that a physical object realises (or participates in) a certain number of universal operators (or 'ideas') in a way that depends on the object. Or we may alternatively say, in Whiteheadian terms, that a universal operator (or 'eternal object') makes *ingression* into the object in an *object-dependent way*. The ingression of a universal operator into an object defines what we shall call a *self-operator* of the object.[28] As we shall see below, the self-operators of an object perform the self-synthesis of its phenomenological multiplicity of phases. In Figure 1, Colin participates in the universal operators ξ and θ. The ingressions of these universal operators define the self-operators ξ_{colin} and θ_{colin}. On the contrary, Colin does not participate in the 'idea' η. By means of this Platonic terminology, we want to convey the idea that an object can be characterised by the way in which it participates in a certain number of universal ideas. Hence, in order to define the *quiddity* of an object we have to specify (1) which are the universal ideas realised by the object and (2) how these ideas make ingression into the object. The important point is that two different objects can realise different universal ideas and/or realise differently the same universal idea. In figurative terms, we could say that an elephant and a giraffe are different because they realise different ideas, and that two elephants are different because they realise differently the same idea. For example, in Figure 2, Colin and the giraffe (whose name is Chloé) participate differently in the same universal operator ξ. This means that the self-operators ξ_{colin} and ξ_{chloe} that result from the corresponding ingressions are different. On the other hand, Colin realises a universal operator that is not realised by Chloé, namely the operator θ. In turn, Chloé realises a universal operator that is not realised by Colin, namely the operator η.

---

[28] It is worth noting that the language of universal entities (and their multiple possible ingressions) is borrowed from category theory (see S. Mac Lane, *Categories for the Working Mathematician* [New York: Springer-Verlag, 1997]). For example, an element a of a set M can be redefined in terms of the so-called *characteristic function* χa from the singleton {*} (which is a terminal object of the category of sets) to the set M. By definition, the characteristic function χa sends the singleton {*} to the element a (i.e. $\chi \mathrm{a} : \{*\} \rightarrow a$). In other words, any element x of M can be defined by means of a particular 'ingression' χx of the 'universal element' {*}. In our case, the universal operators are given by elements of a Lie algebra, whereas the self-operators that result from their ingression are the so-called quantum operators.

We have thus far proposed two alternative ways of characterizing the *quiddity* of an object, namely (1) by means of its invariant objective properties (the 'Husserlian' definition) and (2) by specifying how the object participates in a certain number of universal 'ideas" (the 'Platonic' definition). The first postulate of the quantum theory of physical objects unifies these two ways of defining the *quiddity* of an object:



Universal operators
η
ξ
θ
$p^{\eta}_{chloé}$
$p^{\xi}_{chloé}$
p^{ξ}_{colin}
p^{θ}_{colin}
Different values of the property p^{ξ}
$\eta_{chloé}$ $\xi_{chloé}$
Self-operators
ξ_{colin} θ_{colin}

Figure 2. Elephant meets giraffe

Postulate ♠: an objective property of an object is a particular numerical value that specifies how the object realises a certain universal operator.

For example, two objects that differ in the value of their energy realise differently the same universal operator. In Figure 2, Colin and Chloé realise differently the idea ξ. According to postulate ♠, there exists a property p^{ξ} such that each possible numerical value of p^{ξ} defines a different ingression of the universal operator ξ. In turn, these different ingressions define different self-operators. Since both Colin and Chloé realise the universal operator ξ, the quantity p^{ξ} defines objective properties of both of them. Since Colin and Chloé realise differently the universal operator ξ, they are characterised by different values of the quantity p^{ξ} (namely p^{ξ}_{colin} and p^{ξ}_{chloe} respectively).

We could say that postulate ♠ articulates and formalises the relationship between the 'Platonic' universal *ideas* and the 'Husserlian' *eidos* of particular objects. Indeed, the object's *eidos* (i.e. the set of numerical values of its objective properties) specifies how the object participates in a certain number of universal 'ideas'. Reciprocally, the ingression of certain universal ideas defines the *eidos* of the object. More precisely, the ingression of the universal ideas (ξ, θ, ...) into an object like Colin defines a set of particular numerical values (p^{ξ}_{colin}, p^{θ}_{colin}, ...) of the quantities (p^{ξ}, p^{θ}, ...). These particular values constitute the objective properties of Colin. Hence, the set of these values defines Colin's *eidos*, that is to say the essential *quiddity* that allows us to identify and to recognise Colin through its different modes of presentation.

According to our terminology, the ingression of an universal operator ξ into Colin defines a self-operator ξ_{colin} of Colin. By definition, an operator is a mathematical entity that generates transformations. In particular, the self-operator ξ_{colin} generates transformations of Colin. The second postulate of the quantum theory of physical objects specifies the nature of these transformations:

Postulate ♣: The transformations generated by a self-operator of an object are phase transformations (or automorphisms) of the object.

In other words, a transformation generated by one of the object's self-operators is not an *objective* transformation of the object into another object, but rather a phase transformation that does not modify the object's *quiddity*. This means that the self-operators of an object generate all the possible phantasmatic transformations of the object into itself, that is to say all the different non-trivial declinations of its identity. The self-operators unfold the transformations which, without modifying the object's *quiddity*, permit the observation of its different phases. We could thus say that the self-operators of an object are the generators of its phenomenological presentation.

In order to fix ideas, let's consider again the case of Colin. Let's suppose that, as in Figure 1, Colin participates in the universal operator ξ. According to postulate ♠, there exists a quantity p^{ξ} whose particular numerical value p^{ξ}_{colin} specifies how the universal operator ξ makes ingression into Colin. This ingression defines the self-operator ξ_{colin}. Let's suppose now that the self-operator ξ_{colin} generates rotations around the vertical axis. According to postulate ♣, these virtual rotations around the vertical axis are nothing but phase transformations of Colin. This means that the self-operator ξ_{colin} generates the sequence of Colin's phases that Jean-Sol Partre will observe if he orbits around Colin as in Figure 1. In other words, the phase transformations generated by the self-operator ξ_{colin} unfold the orbit of *lateral* phases of Colin. In this way, the numerical value $p^{\xi}{}_{colin}$ of the objective property p^{ξ} defines the self-operator ξ_{colin} (postulate ♠), this self-operator being the generator of one kind of phase transformation of Colin (postulate ♣). We shall sometimes summarise these two postulates by saying that the objective property $p^{\xi}{}_{colin}$ induces a certain kind of phase transformations of Colin. In particular, the objective property $p^{\xi}{}_{colin}$ specifies how Colin will appear when he rotates around the vertical axis (or when Jean-Sol Partre rotates around him). In this way, each objective property induces an orbit of phases corresponding to a particular mode of presentation of Colin (such as, for instance, rotations around an axis, translations along an axis, temporal evolutions, etc.).

We can now summarise the two proposed postulates by means of the following definition of physical objects:

Definition: An object is a physical configuration that can be completely characterised by specifying the numerical values of the objective properties that induce all the object's automorphisms.

According to this definition, the object's *eidos* (i.e. the set of its objective properties) plays a twofold role, namely it defines the invariant *quiddity* of the object and it induces the object's automorphisms. These automorphisms unfold the different orbits of phases of the object, that is to say the multiple sets of aspects that the object offers to all possible virtual observers. Hence, the imbrication between these two roles can be summarised by stating that *the object's invariant* quiddity *generates its phenomenalisation.* We can also describe this sort of 'speculative theorem' in the following terms: On the one hand, the identification of an object requires an invariant eidetic kernel. On the other hand, the phenomenalisation of an object requires phantasmatic acts, that is to say phase transformations that permit the observation of its different phases without producing any objective effect. Quantum mechanics establishes a link between the 'essence' and the 'appearance' by stating that the *eidos* of an object is the inducer of its phantasmatic acts.

In order to provide an imaginary schematisation of the relationship between the invariant *eidos* and the object's phenomenalisation, we could also appeal to Brion Gysin's *dream machine.* For, in fact, the following stroboscopic experience is at the origin of Partre's persisting hallucinations. Let's consider for instance the orbit of Colin's lateral phases. As we said before, this orbit of phases is generated by the self-operator ξ_{colin}. Let's represent this self-operator as an inner source of yellow light. Let's suppose now that each lateral phase is translucent and that ξ_{colin} is the unique source of light. Thanks to this 'eidetic' generator of light, Jean-Sol Partre can observe the markings on Colin's skin. If Jean-Sol Partre orbits around Colin, he will observe the different patterns of markings of each lateral phase. However, the light that passes through each translucent phase will always be yellow. Hence, the colour of the eidetic radiator that allows Jean-Sol Partre to observe the orbit of lateral phases is invariant under the corresponding eidetic variations. In other words, the colour of the eidetic source that generates the lateral phenomenalisation of Colin is an invariant objective property.

Auyang has already remarked that the 'representation-transformation-invariance structure' that allows the definition of objective properties as invariants under transformations between different representations of a physical system is still valid in quantum mechanics.[29] Nevertheless, the proposed definition of physical objects goes further than the usual characterisation of objective properties as group invariants. Indeed, this definition states *also* that the automorphisms that define the objective invariants are induced by the objective properties themselves. Therefore, we could say that quantum mechanics completes the usual characterisation of objectivity and provides for the first time a satisfactory definition of physical objects.

IV. PACHYDERMAL NOMADOLOGY

> '[...] comment l'objet qui se meut serait-il en un point de son trajet?'
>
> H. Bergson, *La pensée et le mouvant*[30]

We shall now try to establish more explicitly the relationship between the previous definition of physical objects and quantum mechanics. In fact, it is possible to show that none of the proposed postulates can be implemented in the framework of classical mechanics;[31] whereas, on the contrary, quantum mechanics can be considered a satisfactory formal implementation of the proposed definition of physical objects. In particular, we shall now show that Heisenberg's uncertainty principle is a direct consequence of this definition. Roughly speaking, we could say that Heisenberg's uncertainty principle is a formalisation of the virtuous circle that results from the intertwining of objective and non-objective properties.

---

[29] See S.Y. Auyang, *How is Quantum Field Theory Possible?* (New York: Oxford University Press, 1995), Chapter Five.

[30] Paris: PUF, 1938, 158 ('How could the moving object be in a point of its trajectory passage?', H. Bergson, *The Creative Mind: An Introduction to Metaphysics*, trans. M.L. Andison [New York: Dover, 2007], 143).

According to the proposed definition, an objective property is an invariant quantity that induces a particular kind of phase transformation of the object. In turn, a property is objective (i.e. invariant) if it does not change when the object is acted upon by a phase transformation. Hence, objective properties satisfy two conditions, namely (1) they are invariant under all the phase transformations of the object and (2) they induce a particular kind of phase transformations of the object. We can thus conclude that an objective property of an object has to be invariant under the phase transformations *induced by all the objective properties of the same object.* If a property is invariant under the phase transformations induced by another property, we shall say that these properties are *commensurable.* Let's consider for example an object defined by the *eidos* $\varepsilon = \{p, l\}$, where by definition p and l are objective properties of the object. This means that the numerical values p and l characterise completely the object's invariant *quiddity.* The standard definition of objectivity requires that the value of each objective property be invariant under a certain group of eidetic variations. Nevertheless – as we have explained above – this standard definition does not specify *which* group of transformations are to be used for defining the objective invariants. The proposed definition of physical objects bypasses this flaw by stating that the eidetic variations are induced by the objective properties themselves. Therefore, each objective property has to be invariant under the eidetic variations induced by the other objective properties of the same object. The phase transformations induced by an objective property p will be denoted δ_p. In particular, if p and l are objective properties of an object, then they have to satisfy $\delta_p l = 0$ (i.e. l has to be invariant under the phase transformations induced by p) and $\delta_l p = 0$ (i.e. p has to be invariant under the phase transformations induced by l).[32] In general, the phase transformations induced by an objective property of an object cannot modify the other objective properties of the same object. This fact imposes a restrictive condition on the *eidos* of an object. Indeed, the *eidos* cannot be an arbitrary collection of objective properties. Each objective property has to satisfy the condition of being invariant under the phase transformations induced by all the others. This requirement constitutes what we shall call the *clause of self-consistency of the eidos*. This clause states that the *eidos* of an object can only be composed of commensurable properties.

---

[31] A technical presentation can be found in G. Catren, 'On Classical and Quantum Objectivity', *Foundations of Physics* 38, 5, 2008 470-87.

---

[32] Of course, the objective properties p and l have to be also invariant under the phase transformations induced by themselves. In other terms, they have to satisfy $\delta_p p = 0$ and $\delta_l l = 0$. Nevertheless, it can be shown that these conditions are trivially satisfied by any property. The non-trivial conditions stem from the invariance of an objective property under the phase transformations induced by the other objective properties of the same object.

In particular, if a certain property is modified by the phase transformations induced by an objective property belonging to the object's *eidos*, then the former cannot also be an objective property of the same object. This statement can be considered the conceptual translation of Heisenberg's uncertainty principle. In particular, it is possible to show that the momentum p is a property that induces transformations in the position q (and vice versa). Hence, if the momentum p is an objective property in the object's *eidos*, then the position q cannot also be an objective property of the same object. The position q is rather a phase of the object that changes when the object is acted upon by the phase transformations induced by p. In other words, since the position q and the momentum p are incommensurable, they cannot be both objective properties of the same object.[33]

We could say that Einstein was literally right in thinking about quantum objects in terms of dice. Indeed, what God would obtain if he threw a die is not an objective property of the die, but rather one of its faces. And the important point is that a die's face is a die's *phase*. Asking after the objective position q of a quantum elephant with an objective momentum p is as nonsensical as looking for the objective (or privileged) face of a die. Nevertheless, even if a die has no objective face, it will show a particular face when thrown. Obviously, this does not mean that the result obtained was the objective but unknown face of the die. Analogously, even if a quantum elephant with an objective momentum p has no objective position q, it will appear in a particular position q_1 if a measurement of the position is performed. This does not mean that q_1 was the objective but unknown position of the elephant. Neither does it mean that the garden where Colin carelessly wanders splits in parallel paths, such that in each path Colin is in a well-defined position. In any case, a stampede of elephants in a quantum casino will never crush the Copernican revolution: Colin's delocalisation is intrinsic. It cannot be bypassed by appealing to the supposed limitations stemming from a transcendental constitution of objectivity, nor by forking the paths of his garden. Like the faces of a die, the different possible positions q_i of Colin are mere phases with no objective value. In this way, even a single quantum elephant has '[...] une onde [or a die – GC] associée comme flux qui définit l'espace coexistant de ses présences.'[34] We might say that Colin is a deterritorialized quantum elephant with no objective position. Dispersed across the garden, Colin's 'method of resistance [is] always just to keep moving – seeking, not a place to hide out, secure and fixed, but a state of dynamic ambiguity about where [he] might be any given moment, along the lines of Heisenberg's uncertainty principle.'[35]

---

[33] For the sake of simplicity we have only considered the case of an object with a well-defined momentum p and a completely undetermined position q. The reciprocal case – a well-defined position with an undetermined momentum– is completely analogous. In the general case, both the position and the momentum are subject to certain indeterminacies. In fact, the flexibility of quantum mechanics' formalism makes it possible to define physical objects characterised by properties which are neither objective properties nor phases, but rather a mixture of both. In these cases, both q and p are unsharp objective properties of the object. The resulting subtle equilibrium between unsharp objective properties and unsharp non-objective phases is formally governed by Heisenberg's uncertainty principle.

V. QUANTUM CASINO

According to the proposed definition of physical objects, the measurement of a quantum object can be understood as a throw of a die. This means that in general the obtained result will not be an objective property of the object, but rather one of its non-objective phases. Nevertheless, there is a crucial difference between quantum objects and ordinary dice, namely that the former can be superposed.[36] According to our interpretational framework, quantum superposition stems from the intuitive fact that an object is a superposition of phases, aspects or profiles. The important difference is that in quantum mechanics the superposed phases of an object are in turn quantum objects. As in set theory, where a set is a collection of sets, a quantum object is a superposition of phases that are in turn quantum objects. Hence, the superposition of quantum objects produces a new quantum object such that each term of the superposition is one of its phases.

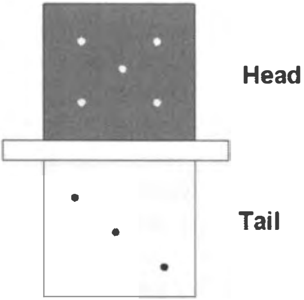

Figure 3. Quantum coin

---

[36] Another significant difference is that the only phenomenological access to a quantum object is by 'throwing' it. In other terms, a quantum object is like a die whose phases can only be observed if one throws the die.

This difference between ordinary dice and quantum objects opens new phenomenological (or experimental) possibilities. For example, we could schematise a particular quantum object as a coin ❍ such that each of its two phases is in turn a die (see Figure 3). Let's denote these two dice as the die-head $■_{\text{head}}$ and the die-tail $❑_{\text{tail}}$. The object ❍, then, is a superposition of the objects $■_{\text{head}}$ and $❑_{\text{tail}}$. Let's write this superposition as $❍ = ■_{\text{head}} + ❑_{\text{tail}}$.

Let's suppose now that in our casino there are two tables, namely a table for playing with coins and a table for playing with dice. So, what can we do with the object $❍ = ■_{\text{head}} + ❑_{\text{tail}}$ in such a casino? First, we can play heads or tails in the table for coins. Let's suppose that, by doing so, we obtain the phase $■_{\text{head}}$. Since the obtained phase is in turn a die, we can go on playing and throw the die $■_{\text{head}}$ on the table for dice. By doing so, we will obtain a number between 1 and 6. The important question is now the following: Can we play with the object $❍ = ■_{\text{head}} + ❑_{\text{tail}}$ *directly* on the table for dice, that is to say without having initially played heads or tails? The formalism of quantum mechanics shows that this is in fact possible. In order to visualise such a possibility, we have to modify the imaginary representation of the object ❍. Instead of considering it as a coin with a die in each phase, we can represent it as a sort of 'hyperdie': We can literally superpose the two dice by putting the die $■_{\text{head}}$ within the die $❑_{\text{tail}}$, such that their vertices are rigidly linked (see Figure 4). If we now throw the hyperdie ❍ directly onto the table for dice, the quantum formalism shows that the probability for obtaining a given number between 1 and 6 depends on the relative orientation (or 'relative phase') between the two dice. For example, the two phases with the

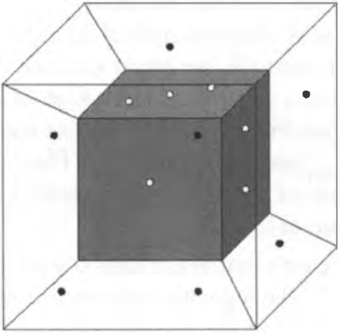

Figure 4. Hyperdie

number 1 might be (among other possibilities) 'in phase' (i.e. aligned) or 'out of phase' (i.e. opposed). If they are in phase, then the number 1 is a possible result of the throw of the hyperdie ('constructive interference'). If they are out of phase, then the number 1 is not a possible result of the throw of the hyperdie ('destructive interference'). In any case, it is meaningless to ask from which die the obtained number comes from.

It is worth noting that a rotation of the hyperdie as a whole (i.e. without modifying the relative orientation between the two dice) is a phase transformation of the hyperdie. Whereas if we modify the relative orientation between the two dice that compose the hyperdie, we will obtain a new hyperdie characterised by another probability distribution. For example, phases that were out of phase might be in phase after the transformation. Hence, a change in the 'relative phase' is not a phase transformation, but rather an objective transformation.

We have only considered thus far the superposition of quantum objects. Nevertheless, in *quantum design*, the construction of objects depends on two fundamental operations, namely the superposition '+' and the tensor product '⊗'. As we have explained above, the superposition '+' permits the construction of a new object by superposing different phases (which are in turn quantum objects). Hence, the terms of the superposition constitute the different 'phenomenological' profiles of the new object. On the other hand, the tensor product '⊗' permits the construction of a single phase by 'pasting' different objects. Whereas the superposition '+' combines two objects as different phases of another object, the tensor product '⊗' combines them as different parts of the same phase.[37]

VI. THE QUANTUM ESSENCE OF MANIFESTATION

This quantum theory of physical objects allows us to resist to the Ptolemaic counter-revolution on two different fronts: First, it shows that quantum mechanics provides a *realistic* and *complete* description of physical objects. The fact that the position q and the momentum p cannot be both objective properties of the same object does not mean that the very *quiddity* of the object depends on the observing subject, on the measurement device or on the experimental context. This means that it is no longer necessary to appeal to a 'transcendental' argument to explain why it is not possible to gain access to all the objective information that defines an object. Hence, quantum mechanics cannot be considered an intra-scientific formalisation of a transcendental limitation of physical knowledge. As Žižek says, the uncertainty principle 'is thus profoundly "Hegelian": what first appeared to be an epistemological obstacle turns out to be a property of the thing itself.'[38] Indeed, the uncertainty principle is nothing but a signature of the intertwining between the invariant *eidos* that defines an object and its experimental phenomenalisation. If the momentum p is an objective property of an object, then the position q is necessarily, like the face of a die, a phase with no objective value. In consequence, the classical description of physical objects, which includes both q and p, is overdetermined. This means that in classical mechanics non-objective properties are wrongly considered objective. We can thus conclude that, *unlike classical mechanics*, quantum mechanics describes all the intrinsic objective properties of observer-independent objects.[39]

---

[37] The mixing of these two operations is at the origin of so-called quantum entanglement. For example, the object $\psi = \alpha \otimes \phi + \beta \otimes \varphi$ results from the superposition of two phases, namely $\alpha \otimes \phi$ and $\beta \otimes \varphi$. These phases are obtained by 'pasting' the objects α and ϕ on the one hand and β and φ on the other one.

But not only does this interpretation allow us to contest the Ptolemaic reductions of quantum mechanics, but also suggests, secondly, a possible intra-physical solution to a transcendental problem, namely the problem of explaining the constitution of physical objects from the manifold of sensible (i.e. experimental) intuition. In Kantian terms, we can say that the unification in the representations of a physical object no longer requires the unity of transcendental apperception in the synthesis of these representations. The quantum theory of objects shows that the 'counting-as-one' of the phenomenological multiplicity of the object's phases is provided by the very *eidos* of the object. Thus the function of synthesis is anchored in the eidetic kernel that defines the *quiddity* of the object. More precisely, the self-synthesis of an object is performed by its self-operators. Each self-operator generates one kind of automorphisms of the object, that is to say a particular sequence of non-trivial 'phantasmatic' transformations of the object into itself. Each sequence of automorphisms connects the different phases belonging to the same orbit of phases. In turn, the self-operators are defined by the objective properties that constitute the object's *eidos*. In this way, the *eidos* that defines the invariant 'essence' of the object induces at the same time the synthetic functions that guarantee the objective consistency of its phenomenological manifold of aspects. In Hegelian terms, we could say that it is the essence of the essence to generate the manifestation of the object. The *essence* of the object is the projector of its *appearance*. Thus the objective consistency of the manifold of experimental intuition is not noetically constituted by the transcendental subject (or the experimental context), but rather induced by the 'eternal objects' that make ingression into nature.

---

[38] S. Žižek, *The Indivisible Remainder* (London: Verso, 1996), 211.

[39] It is worth remarking that this point was recognised by Deleuze and Guattari in very accurate terms: '[...] even in quantum physics, Heisenberg's demon does not express the impossibility of measuring both the speed and the position of a particle on the grounds of a subjective interference of the measure with the measured, but it measures exactly an objective state of affairs [...] Subjectivist interpretations of thermodynamics, relativity, and quantum physics manifest the same inadequacies. Perspectivism, or scientific relativism, is never relative to a subject: it constitutes not a relativity of truth, but, on the contrary, a truth of the relative [...] Of course, a well-defined observer extracts everything that it can, everything that can be extracted in the corresponding system.', G. Deleuze and F. Guattari, *What is Philosophy?*, trans. G. Burchell and H. Tomlinson [London: Verso, 1994], 129-30.

Errancies of the Human: French Philosophies of Nature and the Overturning of the Copernican Revolution

Alberto Gualandi

1. THE 'FRENCH ANOMALY' AND THE RADICALISATION OF THE COPERNICAN REVOLUTION

It is customarily maintained that the Copernican revolution dealt a sort of originary blow to the narcissistic human self-image that had endured for two thousand years. According to Freud, after Copernicus man would have ceased to position himself at the centre of the universe; after Darwin, to position himself at the centre of living nature; and after the psychoanalytic revolution, to position himself at the centre of himself.[1] Within the horizon of contemporary philosophy, it is perhaps the French philosophies of the sixties which radicalised, in a materialist direction, this critique of the anthropocentrism cosubstantial with the Western metaphysical tradition, supplementing Freud's interpretation of the Copernican revolution with the lessons drawn from the other 'masters of suspicion', Marx and Nietzsche.

---

[1] 'A Difficulty in the Path of Psychoanalysis' in *Introductory Lectures on Psychoanalysis* (London: Penguin Books, 1991), 325-6.

The radicality of this critique surpassed that of other national traditions of thought, for it did not stop at recognising the marginal position of the 'human' in the cosmos, living nature and the unconscious psychic system. Rather, it sought to weed out everything that still remained anthropocentric in the Western tradition after Copernicus; beginning with Cartesian dualism, which reserved for the human spirit alone the characteristics of finality and liberty, in an infinite Galilean cosmos, albeit one reduced to a mechanical system (endowed with movement and extension); and reaching as far as the transcendental forms and principles of Kant, who had continued to place the consciousness of man at the centre of the system of knowledge, morality and art.

This radical attitude on the part of French philosophers was not gratuitous, however. For it could be claimed that a number of philosophies which, in the second half of the twentieth century, claimed to draw the consequences of the lessons of Darwin, Marx, Freud, or of the great scientific revolutions of the past century, continued nonetheless to construct their systems upon some form of methodological dualism or linguistic transcendentalism which ended up reserving a privileged place in the system of knowledge for critical reflection on the human – its actions and cognitions, its possibilities and conditions. The French philosophers of the sixties attempted something more audacious: According to them, man and his thought would be but finite forms among others, all engendered on the basis of an obscure and infinite ground that one might call Being or Nature. The most extreme consequence of the Copernican revolution would therefore not be the death of God, but rather the disappearance of Man and of his 'face'.[2]

---

[2] M. Foucault, *The Order of Things* (NY: Vintage Books, 1973), 387.

Now, although the radical character of this enterprise placed French philosophy in an anomalous and solitary position in relation to other traditions of thought, today it must be noted that it anticipated a tendency internal to many contemporary philosophical and scientific approaches whose stated goal is the naturalisation of the human and cognitive sciences. Comparing it with this contemporary tendency, at work in a number of disciplines – from neuroscience to human ethology, via cybernetics and evolutionary psychology – one might even affirm that the French anomaly harboured something more profound. Although the developments of modern science represented a privileged source of inspiration for them, the French philosophies of the sixties believed themselves capable of refusing those determinist and mechanist presuppositions that they attributed, above all, to their predecessor Descartes. For according to them, determinism and mechanism would be but anthropomorphic residues, models of thought that were still too humanist – the result of projecting human schemata of action upon an external nature deprived of its depth[3] – and which every properly materialist thought must rid itself of, if it would think the whole of Life and of Nature. As I shall try to demonstrate in what follows, the pertinence and the richness of this critical attitude, singularly characteristic of French philosophies of nature of the sixties, finds itself confirmed by the epistemological debate, presently in progress in the contemporary life sciences, which turns around problems of ontogenesis and 'actualisation'.

---

[3] G. Canguilhem, *La connaissance de la vie* (Paris: Vrin, 1965), 182; Eng. trans. S. Geroulanos, D. Ginsburg as 'Knowledge of Life' (New York: Fordham University Press, forthcoming 2008); G. Deleuze, *Différence et répétition*, (Paris: Minuit, 1968), 360; Eng. trans. P. Patton as *Difference and Repetition* (London: Athlone, 1994); *Spinoza et le problème de l'expression* (Paris: Minuit, 1968) 207; Eng. trans. M. Joughin as *Expressionism in Philosophy: Spinoza* (New York: Zone Books, 1992).

However, my objective in the following pages will not be to sketch an apologia for an intellectual movement which tried to liquidate its Cartesian heritage by pushing to the maximum the materialist and anti-anthropocentric stance that had animated Western reflexion from Copernicus onward. What I shall try to show is only that this tendency, although legitimate, cannot succeed. It cannot succeed because the critical question raised by the *other* Copernican revolution that shook Western thought – *Kant's Copernican revolution* – continues to represent its unabsolved debt to thought. In the light of this second revolution, anthropomorphism can never be completely liquidated, since the question of the human is always ready to resurge qua transcendental question rooted not in immutable and eternal *a priori* forms and principles, but in the incontrovertible fact that man is indeed the being that interrogates nature, poses its questions to nature.[4]

How to escape this epochal dilemma which tears Western thought in two? Must one follow to the very end the direction indicated by Copernicus' scientific revolution, and end up dissolving the face of man in the 'waves' of an infinite nature?[5] Or must one instead follow the opposite tendency and, radicalising Kant's Copernican revolution, end up affirming, with Husserl, that 'the earth does not move'?[6] In other words, how are we to reconcile the equally legitimate stances of what appear today as the most opposed 'factions': That of philosophers (and scientists) of nature, and that of phenomenologists? And more generally, how are we to articulate the relation between science and philosophy in an epoch where everything seems to point to their mutual and radical exclusion?

Even if it must be brief, our analysis of the 'French anomaly', represented emblematically by the philosophies of nature of the sixties (an analysis to be developed further in part 2, below), and the reconstruction of the ways in which the question of the human resurges in them (and despite them) – at their very heart, in their (analogical) theories of individuation (part 3) – will allow us to foresee a solution which I shall outline in the final part of this text (parts 4 and 5). To place oneself at the centre of the cosmos and from there 'to pose questions to it'; or to displace oneself from this centre, to occupy, through an *eccentric* thought, the point of view of galaxies, of quarks or of neurons; returning to occupy once again the centre of one's own animal body, sensible and self-developing: These are activities accessible exclusively to a rather singular living being. A being which – beyond all suspicion of anthropocentrism or finalism, and in line with the most recent findings of evolutionism – one might also define as that being 'capable of error. A human error which is probably as one with errancy […]

Lawlor (ed.), *Husserl at the Limits of Phenomenology* (Evanston: Northwestern University Press, 2002), 117-131.

and dissatisfaction'.[7] To try to understand more clearly the quasi-biological conditions of possibility of this characteristically human *errancy* – an errancy which, through the proxies of our senses and our bodies (and not despite them, as has often been said) leads us from the earth to the sun and from the sun to our brain – such is the task with which this text ultimately engages.

2. The World 'is' an Egg: Philosophies of Nature, Biological Ontogenesis and Human Individuation

I would like to begin this journey through what I have called the 'French anomaly' with a provisional response to the following question: At the level of philosophical reflection on the natural and life sciences, what happened in France in the sixties that was novel in relation to what had been going on in the preceding decades? I would say that the most apparent change was as follows: In the sixties, epistemological reflection on science gave way to a renaissance of *philosophies of nature*. This renaissance is a new and significant fact, for reasons that I will try briefly to enumerate.

Above all, for reasons internal to the French tradition of reflection on science: In the epistemological tradition of the preceding decades, philosophies of nature had been considered as the lowest degree of reflection on science. Brunschvicg, for example, identified philosophies of nature with the romantic and idealist philosophies of Schelling and Hegel. According to Brunschvicg, the latter took a dangerous step backwards in relation to Kantian epistemology, because not only did their post-Kantian philosophies of nature aim to grasp, in atemporal fashion, the *a priori* principles at work in the science of their time, they claimed to step beyond the methods and results of the different scientific disciplines by identifying ontological laws presiding over the historical genesis of scientific reason.[8]

---

[7] G. Canguilhem, *Etudes d'histoire et de philosophie des sciences* (Paris: Vrin, 1970), 364.

A second notable reason: In my view, this movement of the renaissance of philosophies of nature relates to a tendency that belongs exclusively to French philosophy and which, during this epoch, is absent from other traditions of thought. Outside France, philosophical reflection on science is dominated by critical revisions of the neo-positivist paradigm put forward by authors such as Popper, Kuhn and Lakatos; or, on the German side, by authors such as Habermas. Reflection on science is above all a reflection on the *language* of science, and the Wittgensteinian distinction between the causal domain and the rational domain, the Popperian demarcation between context of discovery and context of justification, or the hermeneutic distinction between explanation and reconstruction, seem to prohibit any contamination between the object of science and the subject of reason, between the human mind and the nature of the objects and bodies studied by physics or biology. In short, outside France, epistemological reflection remains fundamentally Kantian, because it remains a reflection on the logical and discursive structures of the mind and of scientific reason. It is only in the last two decades that things have begun to change, in both England and the United States (and this in spite of the resistance of certain analytic philosophers, who tried to reterritorialize the Kantian transcendental problematic upon language). This change of direction is usually referred to as the programme of the *naturalisation* of the sciences of man and of culture. Everyone today has some idea of what this programme means and what it entails. The only thing I would like to note here is that this programme of naturalisation surely presupposes a certain philosophy of nature and of life, but the authors who put forward the programme do not consider that this conception of nature and of life has anything whatsoever to do with metaphysics, because they believe it possible to draw their conceptual tools from science itself, and in particular from the Darwinian conception of evolution. With the aid of several examples, I would like to show that the current partisans of this programme of naturalisation nevertheless find themselves confronted by problems fairly similar to those posed by the French thinkers who gave life to this renaissance of philosophies of nature.

---

[8] L. Brunschvicg, *L'expérience humaine et la causalité physique* (Paris: Alcan, 1922).

Who are these French authors? I would like to name three: Gilbert Simondon, Gilles Deleuze, and Michel Serres. Which are the works to which I would attribute this turn toward philosophies of nature? *The Individual and its Physico-Biological Genesis*, written at the end of the fifties but published in 1964; *Difference and Repetition*; and *The System of Leibniz* and the two first volumes of *Hermes*. As far as Serres is concerned, I shall limit myself to a few citations through which I believe one can confirm the above claims about the rupture that took place between philosophies of nature in the sixties and Brunschvicg and Bachelard's historical epistemology. From Serres: 'The term "cut" is the mathe-mateme of discontinuity', but it is also the sign of a 'history that is normalised', 'ideal', 'based on a mathematical model', which rests in turn 'on an ethics': the ethics ‘of reform’ and of ‘the founders of the University’.[9] ‘Now, there exists no cut between science and philosophy. […] epistemology is more the *sign* of divorce than the possibility of an agreement, it designates the dehiscence, in trying to reduce it.’[10] This dehiscence can only be surpassed by a ‘new scientific spirit’ which decrees the ‘end of idealist theories of knowledge’ and of historical epistemologies,[11] and which ‘leads us towards a philosophy of nature’, where the information-structure is ‘inscribed’ in ‘the thing itself’, and where one could affirm that ‘there does indeed exist an objective transcendental’.[12]

As for Simondon, I shall limit myself to certain notions that are essential for understanding the rest of my argument. The central notion in Simondon’s system of nature is certainly that which gives the title to his masterwork: The notion of the process of individuation. Simondon’s philosophy of nature is without any doubt a philosophy of ‘univocal being’, since for Simondon a crystal, a drosophila fruitfly, a pig, or a philosopher, are all ‘individuals’. What makes a human being more individual than any other, however, is the fact that the process of actualisation through which a human individual is determined as such does not end at the moment of his death. I shall come back directly to this Simondonian way of posing the question of the human.

[12] M. Serres, *La naissance de la physique dans le texte de Lucrèce* (Paris: Minuit, 1972).

Let us turn now to Deleuze. In a certain sense, Deleuze's philosophy of nature seems the most distant from any possible epistemological interpretation.[13] However, I myself believe that every philosophy must demonstrate a certain comportment in relation to science, and I believe that Deleuze's philosophy of nature is capable of doing so – even that it was capable of doing something more. I said above that, for Brunschvicg, the major failing of philosophies of nature lay in their pretention to overstep science, in a deductive and *a priori* fashion. I am not sure that Deleuze actually made such a claim (extravagant for any historical epistemology). But his philosophy of nature was able to sketch out, according to a method that was neither deductive nor inductive, neither *a priori* nor *a posteriori*, the lines of the evolution or development of science, which were only virtually prefigured in the science of his times, but around which the science of our times is in the process of constructing a new scientific paradigm. To show this, I would like to take the example of biology and, in particular, to return to a celebrated page where Deleuze proposes to us an ontological model of the egg; or, better, the egg as model of the world:

> The world is an egg. Moreover, the egg, in effect, provides us with a model for the order of reasons: differentiation-individuation-dramatisation-(specific and organic) differenciation. We

---

[13] In the Introduction of *Difference and Repetition*, Deleuze puts us on guard against any over-strict epistemological interpretation of his 'metaphysics'. 'A book of philosophy', Deleuze maintains, 'must be in part a very particular type of detective novel'; and 'on the other hand a type of science fiction', whose author knows very well that the usage he makes of science 'is not scientific' (ibid., xx-xxi). Twenty years later, in *Negotiations*, he recalls explicitly that epistemology was never his thing, and that he never considered it necessary to pass through epistemology in order to do philosophy.

> think that difference in intensity, such as it is implicated in the egg, expresses first the differential relations as virtual matter to be actualised. This intensive field of individuation determines the relations that it expresses to be incarnated in spatio-temporal dynamisms […] Individuation always governs actualisation […] Notions such as 'morphogenetic potential', 'field-gradient-threshold', put forward by Dalcq […] take account of this complex ensemble. This is why the question of the comparative role of the nucleus and the cytoplasm, in the egg as in the world, is not easily solved. The nucleus and the genes designate only the differentiated matter – in other words, the differential relations which constitute the pre-individual field to be actualised; but their actualisation is determined only by the cytoplasm, with its gradients and fields of individuation.[14]

This page is most significant, for many reasons. First of all, because it sums up the Deleuzian conception of structuralism, the problem of the relation between structure and genesis, ideal and real, virtual and actual; but also because of its reinterpration of the Kantian problem of the schematism and the transcendental. Secondly, it allows us to bring to light Deleuze's discursive strategies, his way of working with the science of his times, of putting into communication different theories and authors: in this case Simondon's theory of individuation and Dalcq's morphogenetic embryology. Re-read in the light of the great tradition of the philosophies of nature of Spinoza, Leibniz, Nietzsche and Bergson, the Simondonian theory of individuation allows us to see *in the egg a great metaphor of the world*.[15] Here is our provisional hypothesis: Deleuze's philosophy of nature, like every great philosophy of nature, allowed us to go beyond science because it succeeded in identifying the metaphors which underly the conceptualisations of science, its paradigmatic changes, its epistemic ruptures.[16] In what follows, I shall try to clarify further what should be understood by *metaphor*. For now let us try to confirm this hypothesis by returning to the example of the egg.

---

[14] Deleuze, *Difference and Repetition*, op. cit., 323 (translation modified).

[15] According to Canguilhem, one can in fact maintain that the vitalist is someone driven to reflect on the problems of life through the contemplation of an egg rather

What problem is Deleuze coming to grips with by means of this complex set of concepts, in which Simondon's concept of individuation plays an important role? Deleuze, as we know, is an anti-Platonist. As such, he holds that what exists in the immanence of the world is not a copy of a model that would constitute the ideal mould of real individuals. What is real is not *the one* or *the transcendent*, but rather singularities and differences. Now, which concepts in contemporary biology fulfill the function of the transcendent model? Quite obviously, the concepts of biological code and of the gene. For an extremist geneticist such as Richard Dawkins, for example, we are nothing other than the vehicle of our genes, the corporeal envelopes of an information-model which exploits us as much as possible so as to transmit itself from generation to generation. For this ultra-geneticist conception, 'all the various complex aspects of being an organism, being a person, are merely ways in

---

than through the use of a capstan and bellows (Canguilhem, *La connaissance de la vie*, Paris : Vrin, 1965).

[16] In discussing the relations between mechanism and vitalism, Canguilhem reminds us, among other things, that, paradoxically, philosophy can also indicate to science a position which the latter should still occupy, rather than occupy tardily, as Bachelard would have it, an already outdated position (Canguilhem *La Connaissance de la vie*, op. cit.,149).

which our selfish genes program the lumbering robots which constitute us, to serve their, that is the genes', interest.'[17] The most apt and high-performing are those which pass the test of selection. In this model, as can be imagined, there is not a great deal of room for differences. Differences are produced at the source, thanks to the copying mechanisms which Jacques Monod compared to a roulette wheel or a lottery. But once differences are produced, they are selected or eliminated as a function of the unique imperative of the survival of the fittest and best-adapted. In which case, the good news of the 'eternal return of the different' would afford us little hope. In other words, where there is nothing but chance and necessity, there is no longer any space for the virtual and for creation: Everything depends on the matrix, that is to say on the code in which the great book of the world is written.

But in that case, in the light of current biology, what validity can we grant the ontological model put forward by Deleuze in *Difference and Repetition*? I would like to respond to this question with the following citation:

> Living organisms exist in four dimensions, the three of space and one of time, and cannot be 'read off' from the single dimension that constitutes the strand of DNA. Organisms are not empty phenotypes, related one-to-one to particular patterns of genes. Our lives form a developmental trajectory, or lifeline, stabilized by the operation of homeodynamic principles. This trajectory is not determined by our genes nor partitioned into neatly dichotomous categories called nature and nurture.

---

[17] S. Pinker, S. Rose, 'Pinker vs Rose: A Debate', at http://www.edge.org/3rd_culture/pinker_rose/pinker_rose_p4.html

> Rather, it is an autopoietic process, shaped by the interplay of specificity and plasticity. In so far as any aspect of life can be said to be 'in the genes', our genes provide the capacity for both specificity – a lifeline relatively impervious to developmental and environmental buffeting – and plasticity – the ability to respond appropriately to unpredictable environmental contingency, that is, to experience.[18]

I believe this citation suggests a perspective very close to that proposed by the metaphor of the egg. Above all, it tells us that the genotype is not a mould which univocally determines the individual. Between the genotype and the phenotype there intervenes a process of epigenetic development in which the role of the temporal variable is as important as that of the topologico-spatial. Structure is actualised by a process of development which introduces factors of stochastic and temporal variability that singularise the individual phenotype. In other words, organisms 'create themselves through the dynamic interplay of DNA and the cellular orchestra in which it's embedded, and the cells, with their external environment'.[19]

The above citations are not from Deleuze; they are taken from the books and articles of contemporary neurobiologist Steven Rose. They allow us to understand that the problems raised by Deleuze in the sixties are once more at the centre of the contemporary biological discussion. For they touch on the problems, today known as 'evo-devo', concerning the relation between development and evolution, epigenesis and the genetic code, neurobiological plasticity and cerebral modularity. But they touch also on larger questions concerning philosophies of nature and of life, ontology and gnoseology. According to Rose, the rigidly geneticist conception of a theorist such as Dawkins or Pinker – a conception Rose calls 'ultra-Darwinist' – is too static and mechanical, incapable of giving an account of the true becomings of nature. It freezes life and loses its becoming. It transforms 'processes into reified objects'. According to such a conception, true organisms, individual phenotypes, are simply copies of ideal models, which need expend no effort in order to actualise themselves in the concrete world, in the *here* and *now* of natural becoming:

---

[18] S. Rose, *Lifelines: Life Beyond the Gene* (NY: Oxford University Press, 2003), 306.

[19] Pinker and Rose, 'Pinker vs Rose: A Debate', op. cit.

> The crucial thing is this. All living organisms have simultaneously both to be and to become. [...] And it's that dynamic, that self-construction, which is completely lost in the abstract understanding of genes and the behaviors they control.[20]

So as to deepen this comparison and to show that the relation between the Deleuzian concepts and those of contemporary biology is not a vague and pseudo-poetic one, we could construct an argument which, starting with Deleuze's proposed genetic reactualisation of Geoffroy de Saint Hilaire's concept of the plane of organisation,[21] sought to demonstrate that Deleuze attempts to *mathematicise* either the architechtonico-spatial components of genetic structure, or the temporal becomings through which they are actualised. In fact, it seems to me that the Deleuzian enterprise of employing both differential analysis and the topological mathematics of algebraic transformations to think genetic structure and its process of actualisation is close to that of contemporary biology, becoming concrete in the concepts of development genes – concerned with the architectonic structure, the organic *Bauplan* – and regulative genes, which determine the rhythms of its actualisation.[22] For with these two concepts, contemporary biologists try to describe the play of interaction between the spatial and temporal components of genetic structure in the domain of ontogenetic development as well as in that of macro-evolution.[23] As we shall see, these two concepts also have very important implications in relation to the individuative deceleration which characterises the human species as compared to that twin-species with which we share 98.6 percent of our genes – that is, the chimpanzee. Having insufficient space to enter into the details of this somewhat technical argument, I must come straight away to my conclusions.

---

[20] Ibid.

[21] Deleuze *Difference and Repetition*, op.cit.,185.

Deleuze's philosophy of nature is not a vague metaphor in the sense that someone like Alain Sokal might suppose it to be. If it is a metaphor, it is so in a more noble sense, perhaps even in the sense that it grasps theoretical problems of science – problems which even the latter has itself not yet clearly perceived – and systematises them. It is a metaphor in the sense that one could say that every creative intellectual procedure proceeds via metaphor and analogy. For, following Lakoff and Johnson, metaphors and analogies can be defined not as mere rhetorical figures, but as heuristic strategies which allow the conceptualisation of new domains of being and of experience, by transposing structures, schemata or models from one domain of knowledge to another, from a well-known domain to a lesser-known one.[24] Once again, I would like to use some citations to express this idea more effectively. The first is drawn from Stephen Jay Gould who, in posing the problem of the authentically creative method of science, and in particular the method which led Darwin to the formulation of the theory of evolution by selection, states that he has often been impressed by the fact that the theoretical contributions most decisive for the elaboration of the Darwinian theory did not come from biology, but rather from sociology (Comte), from economics (Smith) and from population statistics (Malthus). From this fact, Gould concludes as follows:

---

[22] A. Prochiantz, *Les anatomies de la pensée* (Paris: Odile Jacob, 1997); G. Marcus, *The Birth of the Mind* (NY: Basic Books, 2004).

[23] S. J. Gould, *The Structure of Evolutionary Theory* (Cambridge, Mass.: The Belknap Press of Harvard University Press, 2002), 1322ff.

> If, on this basis, I might advance an hypothesis on what constitutes the common denominator of genius, I would conclude that it is characterised by vast interests and by the capacity to construct fruitful analogies between different domains of knowledge.[25]

According to Gould, in other words, the inventive method of science is 'neither deduction', 'nor induction', but 'what is given in the middle': that is to say, *analogy*. If this is so for science, one might well think that it is even more so for philosophy. And I would say that it is qua faculty of grasping reflexively the metaphors and analogies common to different domains of knowledge that philosophy, even today, can boast of an advantage in relation to science. I also think that it is to the systematic employment of this faculty of tracing passages and analogies[26] that we owe a good part of the theoretical charm exerted by that crafty genius who was Gilles Deleuze. But let us try to be more precise, and to redefine metaphors and analogies through the medium of a more technical concept, that of *transduction* – a metaphorical term itself (originally drawn from bacteriology), which allows us to displace these concepts into the context of the theory of individuation. Simondon writes:

---

[24] G. Lakoff and M. Johnson, *Metaphors We Live By* (Chicago: University of Chicago Press, 1980).

[25] S. J. Gould, *The Panda's Thumb* (London: Penguin, 1980), 57.

> Transduction can be a vital operation; in particular, it expresses the sense of organic individuation; it can be a psychic operation and an effective logical procedure, even if it is in no way limited to logical thought. In the domain of knowledge, it defines the very nature of invention, which is neither inductive nor deductive, but transductive, that is to say corresponding to a discovery of dimensions according to which a problematic can be defined; it is that which is valid in the analogical operation. This notion can be employed to think the different domains of individuation [...] Objectively, it allows us to understand the systematic conditions of individuation, internal resonance, the physical problematic. Logically it can be employed as the foundation of a new type of analogical paradigm, to pass from physical to organic individuation, from organic individuation to psychic individuation, and from psychic individuation to subjective and objective transindividuation, a passage which defines the plan of this research.[27]

---

[26] The faculty of tracing passages and analogies to arrive at models and structures which remain invariant in different domains of knowledge, for example from the mathematical and physical domain to the biological and socio-economic (Deleuze, *Difference and Repetition*, op. cit., 184-6).

[27] G. Simondon, *L'individuation psychique et collective* (Paris : Aubier, 1989), 25-6.

The only objection I would put to Simondon is that this research plan can only be carried to completion in bringing to light the singular place and the crucial communicative role played by that domain of being through which analogical transduction effectively becomes a logical procedure and an heuristic method. In other words, the project that animates philosophies of nature can only succeed on condition of recognising in the human the source and the condition of all metaphorical transduction.

3. ERRANCIES OF THE ULTRA-NEOTENIC ANIMAL

I thus come to the central part of my argument concerning the place which the question of the human holds in the French philosophies of nature. To avoid all sterile polemic on the question of the humanism or anti-humanism of the philosophy of the sixties, I would like to tackle the question from a biological point of view: What place do the philosophies of nature of the sixties reserve for the human animal, within their system of nature or of life? I say the human *animal*, since all the authors I am speaking of would probably agree 'that one cannot remove man from the vital' and that 'the notion of anthropology already includes the implicit affirmation of the specificity of Man, separated from the vital'.[28]

Man, however, is a symbolic animal, and one must therefore take account of the way in which symbolic structures of sense and signification, whether linguistic or pre-linguistic, are rooted in the living body. For the ambition of every philosophy of nature is to retrace a genesis of thought, by retracing the path of the emergence of thought and culture on the basis of nature. The question that must be asked is this: Do these authors succeed in identifying the precise place where the symbolic is rooted in the biological nature of the human animal? Have they not, rather, simply juxtaposed or superposed, in a sort of onto-epistemological parallelism, the question of the symbolic onto that of the living and of animality? And does not this superposition lead these authors to treat the great problems of the sciences and of culture – language, history, society – as simple structural effects, like the products of a spatio-temporal process of individuation that follows the same morphogenetic laws, or the same mathemes, as are in play in the production of nature? And because of this, don't they end up seeing in language, history and society the effects of a machinic calculus that subtracts from human symbolic acts what I would like to call their metaphoric and communicative intentionality?

---

[28] Ibid., 181.

In posing these questions I do not want to maintain a dualist position according to which culture and thought would be the effect of an irreducible irruption. Just as biologists and palaeo-anthropologists such as Gould, Tattersall or Corballis have recently shown, I hold that language, culture and history take to their extreme consequences a logic of restructuring *exaptation* already at work everywhere in the living world. For this logic of *exaptation* or, as Lévy-Strauss and Jacob called it, this strategy of *bricolage*, represents a process of functional displacement or cognitive *transduction* by virtue of which an anatomical, perceptive, symbolic or institutional structure comes to be used for ends different to those which it had at its origin.[29]

However, what remains to be explained is the reason why the *exaptive* bricolage assumes in man a far more important cognitive and heuristic role than in every other animal. Now, the sole response I know to this question is the following: This cognitive transfer is motivated by the fact that man is an animal which, to live, is obliged to establish between itself and the world an analogical and communicative relation. It is because of this originary communicative relation that a symbolic structure must not be considered as the simple result of a 'connectionist calculation'.[30] I am of the view that every symbolic structure, in fact, attempts to resolve a typically human problem, the problem posed by the fact that every process of symbolic individuation can only be accomplished in man in an indirect fashion, that is to say by virtue of the mediation of the *Other*. We might underline the philosophical consequences of this thesis in familiar terms, in the following way: Every process of cognitive individuation of external reality is metaphorised by a process of subjective individuation, just as every process of individuation of the structures of reason and of mind is mediatised[31] by processes of individuation taking place in external reality. Simondon once more: 'The individuation of the real external to the subject is grasped by the subject by virtue of the analogical individuation of knowledge in the subject […] This grasp is therefore […] an analogy between two operations, which amounts to a certain mode of communication'.[32] Now, to what is owed this analogical mode of communication which is at the basis of all animist and anthropomorphic, totemistic, religious and transcendent phenomena,[33] but which is also at the foundation of the fact that man is the only living thing that has a need to identify itself metaphorically with the Other – another animal, a machine or even a God – to know what he is and how he should act in the world?

---

[29] According to a neurobiologist such as Vilayanur Ramachandran, or a cognitive linguist such as George Lakoff, the basis of this heuristic transfer is to be found in the diffused hyper-connectivity of the human brain which permits the establishment, in the course of the process of human ontogenesis and phylogenesis, of synaesthetic and symbolic relations between the different sensori-motor modalities, between cerebral regions which preside over the elaboration of the data of hearing and sight, and those which preside over the control of the hand and voice. The hypothesis that the process of anthropogenesis could have passed by way of the liberation of the hand and the restructuring exaptation of the phono-auditive apparatus would find here a neurobiological confirmation.

[30] P. Maniglier 'Il calcolo delle culture. Lo "strutturalismo" nella storia dell'intelligenza artificiale' in *Discipline filosofiche*, XII, 1, 2007.

To respond to this question, we must once more turn to biology, reformulating the question as follows: If we remove from man the faculty of understanding and elaborating that group of more or less abstract and conventional information which are symbols and signs, must we then consider man an animal like all the others? For ultra-Darwinist biologists and psychologists such as Dawkins and Pinker, man is very simply an overendowed ape, to which a surplus of 900 cubic centimetres of cerebral matter furnishes cognitive modules, genetically predetermined, which allow it to accede to the dimension of language and other cultural significations. For a biologist such as Gould, but also for neurobiologists such as Ramachandran, Gary Marcus or Alain

[31] See for example Simondon's critique of the hylomorphic model of Aristotle and Kant, and Serres's metaphorological analyses.

[32] Simondon, *L'individuation psychique et collective*, op.cit., 30.

[33] Serres, *La naissance de la physique dans le texte de Lucrèce*, op. cit.,150-1.

Prochiantz, however, this response risks attributing to man *too many* qualities, in making him the contrary of what he is.[34] Man is not a hyperadapted animal, but rather a *neotenic ape*, with a delayed ontogenetic development, which natural selection favoured at a time of great climatic change[35] because of its maladapted and 'infantile' character, because of its quasi-fœtal cerebral plasticity, which permitted it to specialise in (territorial) non-specialisation, in communication and in sociality.[36]

It may be noted that this neotenic conception of man is close to the Simondonian conception of individuative retardation which opens the human being onto the transindividual, psychic and social dimension of the symbolic. But it also comes close to the Deleuzian conception of man as the essentially deterritorialized being, and Canguilhem's thesis according to which man is distinguished from every other living thing by that anxious errancy which pushes him continually to modify his conceptual *a prioris*. For, let us recall in passing, this conception had already been known in France since the beginning of the thirties, above all thanks to Gawin de Beer's work *Embryologie et évolution*. In his major work, Simondon also cites Lodewijk Bolk, as well as the concept of neoteny,[37] and one of the categorial couples used by De Beer's embryology is that of virtual and actual, later to be reprised by Simondon and Deleuze. In reprising the thesis formulated by Bolk in 1926, De Beer, in this little book, proposes a heterochronic conception of development and evolution, emphasising the concept of human individuative retardation or neoteny.[38] This conception would later be taken up again by Gould, who would show (after Portmann), how human temporality must in reality be characterised by a double heterochronic phase, defined by certain authors as ultraneoteny.[39] In human ontogenesis, the individuative retardation – expressed above all in the almost disproportionate prolongation of the condition of neonatal and infantile dependence (and then in adolescence and in a period of post-reproductive old age), but also, at the morphological level, by the conservation of fœtal characteristics (concerning the reduced size of the mandible and the ocular cavities, or the advanced position of the *foramen magnum* and the vagina) – is preceded by a phase of intra-uterine acceleration.[40] This phase of intra-uterine acceleration is characterised by an increased rate of brain growth whose consequence is a premature birth (around ten months early).[41] This birth is rendered necessary by the form of the pelvis in the female biped, but also by the cognitive and behavioural advantages that the human species received from the fact of its possessing a quasi-fœtal brain which is exposed to the conditioning of the familial and natural milieu in a premature and still very plastic state. This brain, which comes into the world 23 percent developed – as opposed to the roughly 40.5 percent of the chimpanzee[42] – would however be completely inapt to face the world, and to make sense of the profusion of *meaningless stimuli* to which it finds itself exposed, if it was not in a position to transpose into all sensorial modalities the communicative structure which links the infant to its mother and which the auditory modality had already begun to exercise in the darkness of the uterine night.[43] This communicative structure is what allows different sensory modalities to maintain synaesthetic and metaphorical relationships which distinguish the brain of the human animal from that of every other animal. In conclusion, *man is a symbolic animal because its ultra-neotenic condition imposes upon it the maintenance of a communicative relation with the Other in order that it might begin, and pursue in a sufficiently successful fashion, its process of cognitive, emotional, social and linguistic individuation.*

Now, I believe that this neotenic conception of the human animal has most significant consequences for philosophy – or, better, for the relation between the natural and biological sciences and the human sciences, such as cultural anthropology, psychoanalysis, linguistics and sociology. On the other hand, I believe that this problem allows us to identify a true difficulty with structuralism, because if one does not take account of this communicative structure which orients human anthropogenesis, then the onto-epistemological isomorphism or parallelism between natural structures and psychic, social and cultural processes of individuation becomes merely what Aristotle would call a *metabasis eis allo genos*, that is to say a categorial transgression or 'category mistake' which, to cite Serres or Simondon once more, could also be defined as a 'bad analogy'.[44] It is an analogy behind which one might also recognise the transcendental illusion which leads to the presumption of a new absolute knowledge and to the scientistic suppression of that effort of critical reflection concerning human knowledge and its history, which – beyond every legitimate aspiration to a rebirth of (anti-finalist) metaphysics of nature and of life – is also philosophy.

4. THE MÖBIUS BAND OF BEING AND THOUGHT

Let us try now to systematise the analyses presented above in a critical fashion. At the heart of these analyses we saw emerge forcefully the 'fundamental thesis, without which human experience in general would remain incomprehensible: the thesis of the *communicative character* of this experience'.[45] In its most general signification this thesis denotes a set of dynamics singularly characteristic of human experience: metaphorical and synaesthetic translations, functional restructurings and 'cognitive mappings', sensori-motoric exaptations and inferential invariances which permit a circulation among different domains of experience. These dynamics are essentially characteristic of human experience because it is thanks to them that a communicative and circular relation is established between the internal and external world, between individual consciousness and the social milieu, between the human world and natural reality.[46] Although propositional language represents the principal vector of this experiential dynamic, the roots of the communicative structure of experience go deep into a sensory and pre-linguistic dimension, a dimension which furnishes the 'embodied' foundation of the syntactic, semantic and pragmatic structures of 'audio-vocal' language. This thesis has a crucial importance for the horizon of contemporary philosophy. In fact, to describe this set of communicative dynamics means, on one hand, to stay close to the task which phenomenology assigned to philosophy.[47] On the other hand, this task is perhaps also compatible with that proper to an epistemology which, in transgressing the indications of phenomenology, refuses to resign itself to accepting the antinomies which our epoch imposes upon philosophy: The antinomy between sensory experience and propositional language (and, consequently, mathematical symbolism); the antinomy between Kant's 'Copernican revolution' and Copernicus' own. In what way might these antinomies be surpassed?

How the Embodied Mind Brings Mathematics into Being* (NY: Basic Books, 2000); V. Ramachandran 'Hearing Colors, Tasting Shapes', in *Scientific American* 288, 5, 2003: 42-9.

[47] This task might be described effectively as follows: 'To explore human experience, revealing its depth and wealth, instead of reducing it, [...] and to resist the temptation to take [the data of experience] for coded signs which reveal their true meaning only after an intricate process of deciphering' (E. Straus, in H. Spiegelberg, *Phenomenology in Psychology and Psychiatry* (Evanston: Northwestern University Press, 1972), 263, 267.

If we are today to sketch out an adequate image of the human being and its singular mode of experience, we must try to construct a sort of *theoretical interface* capable of establishing a *circular* and *communicative* relationship between science and philosophy. It is firstly a question of avoiding the imprisonment of theory between the aprioristic schemata of philosophy, but also one of avoiding forcing it into a scientific empiricism insufficiently elucidated in terms of a comprehension of its own conceptual foundations. The word 'theory' should therefore not be understood here uniquely as 'a *static* set of propositions in accord with the facts', but also as an interpretative *dynamic* in a state of circulation 'from below to above'; and, inversely, from 'above to below': from concepts to experience, and vice versa. It is a question here of putting into communication the customarily separated dimensions of 'subjective intentional sense' and 'objective empirical facts', without falling back into the rigid separation between *Naturwissenschaften* and *Geisteswissenschaften.* This rigid distinction is inapplicable in the present context, since the object and the subject of investigation are 'the same':[48] man in his unity and his corporeal and spiritual determinations. In other words, it is a question of giving an account of human experience in the duplicity of its *natural* and *cultural* determinations. On one hand, an experience rooted in a *biological, natural body*, in its singular physiology and sensoriality; on the other, an intentional experience which is constructed and developed in a communicative relation with the *Other*, which is structured and stabilised by virtue of the institutionalised forms of *cultural* intersubjectivity.

---

[48] E. Husserl, *Crisis of European Sciences and Transcendental Phenomenology* (Evanston: Northwestern University Press, 1970), §53.

In the light of these methodological presuppositions, the central thesis animating this new image of the human could well be reformulated in the following way: Since the human body is an ultra-neotenic body – organically non-specialised and cognitively speaking not 'pre-wired' for any specific determinate milieu – human experience is coordinated and structured in a communicative relation with the Other, compensating for its extra-specific instinctive deficit through communicative, intra-specific and quasi-instinctive 'circuits', which 'from our origins' (phylogenetic and ontogenetic) have favoured in a determinative fashion the survival of the species. In other words, the alterity towards which the *erfahrende Bewusstsein* intentionally transcends is not originarily that of the object or of the external world (the *Allon*), but rather that of other human beings: the *Heteros*.[49] Or, in still other words, the relation with the object is 'intentioned' in a metaphorical and mediated fashion by the relation with the *Other*. To affirm this does not mean, however, rushing headlong into an 'intersubjective idealism', denying that the 'external object' possesses an 'ontological' existence 'already', or that it has a (physical, chemical, biological) structure *in itself*. It means, rather, affirming that this object is not yet endowed with a sense *for us* and *for itself*. The fundamental theoretical kernels of the two antithetical conceptions of the movement of auto-constitution of the human spirit – phenomenology in its Hegelian and Husserlian guises – are thus superposed, their features now agreeing.

---

[49] E. Straus, 'Psychiatrie und Philosophie', in H.W. Gruhle, R. Jung, (eds), *Psychiatrie der Gegenwart*, Band I/2, (Berlin: Springer, 1963), 969.

What there is of truth in transcendental philosophy and in phenomenology – that is to say, in the fact that human consciousness is self-constituted in the course of an historical and intersubjective genesis whose sense is not predetermined in advance and which, opening onto the future, is thus always exposed to the risk of falling back into the past – must not, however, make us forget that the foundations of this genesis project their roots back into *Nature*. As was shown by the French philosophers of the sixties, along with the contemporary biologists which we have met along our way, man is only one living form amongst others: A form which has detached itself, during an infinitely short time, and 'by way of an hereditary error', from the obscure and chaotic ground of a nature which ceaselessly actualises itself by bricolaging '*a priori*' structures and forms (which we share with all the other animals), and upon which are founded our cognitive strategies for the capture of information which, in large part, is already inscribed in things.[50] In this sense, human 'knowledge' cannot be anything other than the 'anxious search for the greatest quantity and the greatest variety of information. Consequently, to be a [human] subject of knowledge, if the *a priori* is within things, if the concept is in life, is only to be unsatisfied with the sense that is found. Subjectivity is thus nothing but dissatisfaction. But perhaps this is life itself.'[51] From this point of view, contemporary biology thus harbours a 'philosophy of life'[52] whose aspirations would be no less totalising than those (opposed to it) advanced by the philosophies of history and of consciousness. But, after all that we have said about the neotenic nature of man – and the interactive (stochastic and temporal) play between information and milieu, between structure and actualisation, strongly amplified by the human brain – can we stop there? To accept in their ultimate consequences the stances taken by these philosophies of nature and life seems to project us into a profoundly contradictory situation, where the specific pertinence of 'human errancy' in the 'metaphorico-transductive' process of knowledge – a pertinence which we have tried to bring to light throughout the above – becomes 'erased' by the great current of life. Can we be satisfied with this dazzling short-circuit between being and thought; or, in other words, with this unsurpassable antinomy between philosophies of being or nature and philosophies of consciousness or culture?

---

[50] Canguilhem, *Etudes d'histoire et de philosophie des sciences*, op. cit., 364.

Let us try first of all to take the measure of this apparently contradictory situation by conceptualising it symbolically, which means assuming this situation in all seriousness by pushing to the maximum the circular dynamic which it ceaselessly engages. The appropriate symbol is that of the Möbius band, where it is always possible to reverse the relation of foundation between 'that which founds and that which is founded': between subject and object, theory and experience, intentions and causes, science and philosophy. This possibility of reversal is owed in the last instance to a fact that is at once banal and paradoxical, and whose meaning we have not yet completely grasped. On the one hand, man is an infinitely small part, an infinitesimal element, of a nature which surpasses him spatio-temporally on every side and which envelopes him as an All; on the other, this idea of 'Nature', just like the Kantian idea of the 'world', 'is neither object nor concept'. For it is founded and constituted by virtue of a mental activity which is necessarily rooted in a body and which is necessarily 'centred' on sensory and cognitive structures which belong inalienably to it. Its mental activity – including scientific activity – can never be emancipated or completely abstracted from these structures. This is why all those who, from Bachelard onwards, considered that the Copernican revolution, just like every other scientific revolution after it, determined a complete and definitive rupture with the body and its sensory modality of knowledge, are seriously mistaken. In my view, the whole problem is rather to comprehend how there can exist an animal that is capable of causing its thought to 'get out' of its body, and from the relation that every animal maintains with its milieu,[53] so as to install this thought in the place of God, of the sun, of the proton, the neuron, and from this point of view – errant and anxious, taken up in an unsatisfied and incessant movement – to watch itself live, know, and think.

---

[51] Ibid.

[52] Ibid.

Returning for now to the Möbius band and to this unsurpassable circularity: If, from the point of view of science, it is natural causes and processes that produce an individual body and engender consciousness, from the point of view of modern philosophy, the causal concepts of science are but theoretical abstractions progressively constructed in the course of a genesis whose point of departure must be the 'intuitions' of sense and the *a priori* structures of consciousness. Let us represent the first 'side' of the band as a sort of *eccentric* dimension in relation to the human, to its body and its consciousness, a sort of *Copernican vector* typical of modern science (and paradoxically, of ancient science).[54] From this point of view, Kant's Copernican revolution – the continuation and deepening of Descartes' 'subjectivist' revolution, and the anticipation of Husserl's 'phenomenological revolution' – is not completely symmetrical, in the domain of philosophy, with the scientific revolution unleashed by Copernicus, but rather precisely its *reversal*. This gives the impression of a complete opposition, a radical divergence between science (centred on the category of causality) and philosophy (centred on the category of intentionality). For, whereas science identifies in finalist anthropocentrism the insupportable evil of philosophy,[55] philosophy accuses science of objectifying man and of dehumanising the world and the life upon which all scientific enterprise is founded.[56] Whereas science tries to mobilise our reflection ever more by pushing it to adopt the point of view of the solar system, the universe, the subatomic particle or the neuron, modern philosophical consciousness arrives at the scientifically scandalous affirmation according to which the Earth, qua originary soil of all quotidian and scientific knowledge, 'does not move'.[57] Hence the exigency of defining a new circular and communicative relation between science and philosophy, fit to take account of the necessary complementarity between the *critical* and *eccentric* dimension of man[58] and his singular place in the All of Being or of Nature.[59] This exigency nevertheless finds in our perspective, a collocation different from that which philosophy usually assigns it: The pivot of this communicative relation is not represented by the 'transcendental ego', a self-evident object or a self-conscious subject of thought, but rather by a body that senses and develops in relation to its milieu according to intentional modalities of a particular type. An ultra-neotenic body that, in the course of the anthropogenic process, has discovered strategies that have permitted it not only to see, touch and move in a singular fashion, but also to speak of the Other and, ultimately, to *hear* itself *think*.

5. EMBODIED TRANSCENDENTAL PHILOSOPHY

The methodological hypothesis orienting our research is that the 'eye' and the 'ear', the 'hand' and the 'voice' represent corporeal-mental structures around which pivot the communicative relation between the 'eccentric' vector of science and the ‘centric’ vector of philosophy. Organs and functions of objective and biological bodies and, at the same time, *a priori* structures of phenomenological consciousness, the human senses can only be described in their function as ‘interfaces’ between mind and world by reconciling an objective ‘third-person’ description with a subjective ‘first-person’ modality. If no-one can know what seeing, touching or hearing means without being afforded the possibility to accede directly and in the ‘first person’ to the different modalities of sensory feeling; no-one can say what effect proves one is a ‘human being’ without situating oneself at the ‘centre’ of a singular body that, even before it ‘thinks’ in objective fashion, must be lived, in the first person and subjectively, according to the synaesthetic and metaphorical modalities unavailable to any other animal. Although for man, as for other animals, the senses represent those *material a prioris* that function as ‘categorial axes’ around which turn the relation of mutual implication between consciousness and milieu, human beings seem capable of constructing a scaffold of intrasensorial schemata, ever more exempt and abstracted from the corporeal *hic et nunc*, and which find their highest expression in audio-vocal language.[60] My suggestion is that our experience of our own ‘mute thought’ or interior dialogue – an experience upon which, in large part, our feeling of self-consciousness and self-determination is founded – is in reality closely linked to the function of silent self-hearing which the ear gradually assumes in the course of the phylogenetic process of anthropogenesis (*hominisation*). If we must therefore maintain – just as the partisans of the ‘linguistic turn’ do – that it is in language that the question introduced by the 'what' ('What is man?') changes sign, being transformed into the question concerning the 'who' ('Who is man?') of he who asks the question; it is also true that the mute and silent thought which we identify with our interior 'I' is rooted in the terrain of a sensory activity already endowed with its own intentionality.

---

[60] A. Clark, *Being There* (Cambridge, Mass.: The MIT Press, 1997).

As Helmuth Plessner and Erwin Straus have shown, this originary sensory intentionality can only be grasped by carrying out a reversal of direction in every objective description – physiological, neurobiological, behavioural – of sensory activity, a reversal which results in replacing the third person with the first. And so it is that, at the precise point where this replacement happens, the fundamental philosophical question concerning the conditions of possibility of experience is reintroduced, through a sort of reversal or epistemological *Umkehrung* internal to the eccentric and objective descriptions of science and the philosophies of Nature. In a certain sense, this reversal of perspective, which is also a reversal of the Copernican revolution, is not new. Plessner calls it 'critique of sense' or 'aesthesiology', and maintains that every biological science or philosophy of nature and of life which claims to assign man his place in the order ('vertical' and of growing complexity) of living nature, absolutely cannot pass from this ('horizontal') dimension which, in their 'heterogeneous unity', the senses half-open to the 'transcendental I' of consciousness. This aesthesiological reversal was then radicalised by Straus in a phenomenological direction, by showing, on one hand, that only the activity of sensing allows us to accede in the first person to that which is *real*; and on the other, that the aesthesiological analysis of diverse sensory modalities allows us to avoid all recourse to an intentional consciousness which – as is still the case in certain analyses of contemporary neurobiologists who wish to explain in purely causal and objective fashion the engendering of consciousness on the basis of bodies and emotions – *contemplates* sensory contents from without, like a spectator who *watches* a 'film' that passes before the mental *eye* of *its* consciousness.[61] In conclusion, according to our hypothesis the paradigm of the ear and the voice would allow us to surpass the tactile and ocular dichotomies which are still at the basis of contemporary science, as well as transcendental philosophy.

Qua sensing and self-developing organism, the living body is already endowed with an intentionality in relation to its milieu. In being incarnated, however, in a multiplicity of sensory modalities, this intentional structure is split into a plurality of *a priori* forms concerning space and time, the possible and the real, the extensive and the intensive, distance and direction, passive and active character, pleasure and pain.[62] These categorial structures, incarnated in different sensory modalities, pose the problem of their order and their integration into a unitary structure, of which the 'transcendental I' is a *result* rather than a *condition.* In Straus, Plessner and Gehlen's aesthesiological perspective, the 'Mind's I' is the product of intrasensorial schemata capable of surmounting this modal difference by transcending the dimension of the corporeal *hic et nunc* through contents of experience ever more abstracted from direct sensory contact with reality. Visual data are thus allowed to symbolically take the place of tactile data, the phono-auditive gesture to replace visual data, and ultimately the ear comes to relieve the voice, by becoming silent discourse or mute thought. This aesthesiological redefinition of the Kantian problem of the schematism of the imagination plays a crucial role in our attempt to establish a communicative relation between contemporary science and philosophy. On the neurobiological side, this aesthesiological hypothesis today finds corroboration in those theories that try to explain the emergence of consciousness without reference to any central instance assigned in advance the task of integrating information coming from different cortical regions. On the palaeo-anthropological side, it finds confirmation in those theories of cultural phylogenesis which identify in the processes of anatomical and cerebral exaptation, in the strategies of motor and sensory exemption, and in the synaesthetics and the metaphors between different cortical regions, the very vector of the process of anthropogenesis (*hominisation*). In light of these theories, internal self-consciousness now appears as a sort of 'refolding' or 'circumvolution' of a 'phenomic surface' – deprived of all topological distinction between interior and exterior, since it lacks all 'thickness' – which is incarnated in the aesthesiological structures of sense and perception. It is this absolute phenomenological surface[63] which might be considered as the veritable matrix of sense, the Möbius band of which we spoke above.

But the model of the Möbius band can also be developed in the other direction, that is to say in the direction of a 'critique' of the structure of experience which science presupposes as ontologically already given at the foundation of its action of knowing. If everything that is determined by language, by science, or by any other type of theoretical abstraction, presupposes the originary and uncircumventable ground of 'sensing',[64] aesthesiology might then assume the role formerly occupied by transcendental epistemology. In other works, we have, for example, tried to indicate the consequences that might be drawn from this transcendental aesthesiology at the level of mathematical philosophy.[65] The problem of the relation between the finite and the infinite, the continuous and the discrete, can only be conceived dynamically by a living being for which it is necessary, from its birth, to harmonise the fundamental phenomenological difference which separates the aesthesiological structure of haptic touch (an active, discrete, repetitive and algorithmically finite structure) from the heterogeneous and nuanced structure of vision (a passive, continual and virtually infinite structure) through invariant relational structures constructed in large part through analogy.[66] Similar consequences could also be drawn at the level of the epistemology of physics; in demonstrating, for example, that the concepts of cause and of natural law necessarily contain metaphorical elements derived from the feeling of necessity that humans feel when faced with the 'conventions' of language and other laws which regulate their social action;[67] and, more profoundly, from the feeling of vital auto-affirmation which we derive from our intentional movements and acts.[68] These analyses might, however, also be deepened in relation to that ontological terrain, common to scientific knowledge and traditional philosophy, which is constituted at the crossroads of a well-determined intrasensorial schematism: The objective properties or primary qualities of the real, upon which Western science has founded its ontology since Galileo and Descartes, up to the great rupture of quantum physics; for what are they if not the product of a common tactile-ocular sense of which humanity had already had a first intuition beginning from Aristotle and Democritus? And how to explain the 'substance-accident' syntax of experience which, from Aristotle onward, has been recognised as lending its basis to propositional language, without reference to the tactile-ocular schematism from which the linguistic imaginary of scientific knowledge still struggles to free itself today?

[66] A project very close to the present one, critically analysing the 'embodied' transcendental foundations which underly mathematical construction, is that of F. Bailly and G. Longo, *Mathématiques et sciences de la nature. La singularité physique du vivant*, Paris : Hermann, 2006 – see esp. 41-3. Longo and Bailly's approach shows us, amongst other things, that in contemporary French philosophy the question of the human is far from having been definitively liquidated.

These are only a few examples which cannot, in the present text, be translated into an sufficiently articulated epistemological analysis. To acquire a sufficient theoretical coherence, these examples would have also to integrate the question of the conceptual foundations of contemporary biological knowledge, from which this article has drawn many of its arguments. This question is not, however, no stranger to our approach, since the critique of the 'machine' model, which serves as the foundation for the classic cognitivist theories of the elaboration of information, and which even governs the functioning of a number of contemporary theories of the genetic code and its informational structure, represents a prime example of it.[69]

In order for the Möbius band to successfully develop in the right direction, we must however return once more to the analysis of the modalities through which the living being incarnates in itself the forms which serve to interpret the real for it.[70] The theory of spatial structures incorporated in the genetic *Bauplan* of an organism, as in the aesthesiological structures which permit a living body to relate itself to its milieu, surely furnish us with a powerful model of description.[71] From this point of view, human experience might distinguish itself from that of other animals by its capacity to translate the aesthesiological structures of different sensory modalities one into another according to plastic and flexible dynamisms that contrast with the strongly hierarchised organisation of other animals.[72] This strongly metaphorico-analogical modality of intrasensorial translation[73] – a modality that is not rigidly predetermined by the species (nor determined *a priori* by a univocally digital code, as Artificial Intelligence would have it) – leads us once more to the fundamental anthropobiological condition which makes it possible: The ultra-neoteny of the human body and brain. In thus elevating ourselves to the anthropobiological condition of possibility for our specific modality of making experience from reality, the status of this ultra-neotenic character of human nature is thus transformed from a scientific hypothesis into an uncircumventable phenomenological fact; into a sort of *material a priori* whose signs can be seen in the way, the errant and anxious way, in which our experience unfolds in every domain of its expression – beginning with that centrico-eccentric dynamic of experience that is at the base of Kant's Copernican revolution, but also that of Copernicus himself.

---

[69] This epistemological critique which, with philosophical intelligence, contemporary biology addresses to its supposed precedents, is today confirmed also by mathematicians who work on the *incorporated* foundations of their discipline (see, for example, Bailly and Longo, *Mathématiques et sciences de la nature*. op. cit.).

6. THE REVERSAL OF THE COPERNICAN REVOLUTION AND THE METAPHORICAL ERRANCIES OF THOUGHT

Let us return now to Copernicus, so as to draw a philosophical conclusion appropriate to his scientific revolution. According to a now canonical interpretation, the revolutionary character of Copernicus' system determined a clear and definitive rupture between sensory experience and scientific reason, and imposed a drastic reduction of philosophical anthropocentrism. I would like briefly to try to show that this interpretation is false, or at least only partly true. As far as the question of meaning is concerned, we must first of all note that the contrast between sensory experience and Copernicus' theory 'is much more radical than the difference between a correct and an erroneous judgement'.[74] Following Straus and Husserl, in fact, it can be maintained that Copernicus did not simply replace a false sensory judgment ('the earth does not move') with a true judgment ('the earth moves'), but that he left the primary dimension of sensory experience so as to accede to a conceptual dimension, abstract and exempt, by virtue of which scientific thought apparently disengaged itself from all anchorage to our earth and to every living, sensing and self-moving body alike. Scientific thought thus *imagines* seeing the earth, the sun and the stars from an 'excarnate' and eccentric point of view which had not been possible for any human being before Copernicus: an 'intellectual vision' so powerful that it could be compared to the vision of God.[75] But is this scientific vision as *absolute* as we would like to believe it is?

[74] Straus. 'The Expression of Thinking', op. cit., 281.

[75] 'When Copernicus conceived and elaborated the heliocentric system, he did not watch the skies; neither did he wait for the night to observe Jupiter, Mars and Venus; nor for the day to see the sun rising and setting. He thought about cycles and epicycles. While in his thoughts he was concerned with the constellation of the stars in their continually changing positions, he was not bound to any particular place or time in his thinking. He used, of course, all the observations made on this globe by astronomers before him. But the heliocentric system deals with the relation of sun and star, envisioned as if it were from a point outside of the solar system and certainly from a position removed – in thought – from the earth, which Copernicus had cut loose from its moorings and enlisted in the company of the other planets. The Copernican system discussing the revolutions of the celestial bodies comprehends, in one view as partners in one relation, the sun and the stars, which are actually never seen together by a terrestrial observer. In this and in many other aspects, Copernicus' thoughts firmly contradict, or at least seem to contradict, the testimony of the senses. Western man knows that the sun is at rest; nevertheless, all of us – the astronomers not excepted – see that the sun moves, rises and sets. But this is not sufficient reason to condemn sensory experience as deceptive, for the contrast between seeing and thinking is much more radical than the difference between a correct and an erroneous judgement.' (Ibid., 280-1).

In the first place, it must be noted that this powerful theoretical vision bequeathed us by Copernicus does not furnish a sufficient reason 'to condemn sensory experience'.[76] As Straus and Husserl remind us, the construction of the mathematical imagination which a scientific theory is, must above all be in a position to rediscover the way that permits it to 'come back down', more or less mediately, to the level of 'centric' experience as delivered by the senses and the body.[77] If this were not to happen (neither today, nor tomorrow) the theory could be judged neither true nor false, but only as incapable of entertaining any relation whatsoever with the *reality* of this world.

Secondly, we must consider as one of the great lessons of the relativist and quantum revolutions of the twentieth century, as of the 'embodied' reflections on the foundations of mathematics and physics, that contemporary science is less excarnated and 'absolute' than its classic image claimed to be. In fact it does not seem able to progress along the generalising path of theoretical abstraction without enveloping in its mathematical symbolism the reference system or the concrete 'point of view' from which the subject of knowledge localises, measures, and marks out the reality of the world. But if, on one hand, this fact demonstrates the theoretical power and the philosophical profundity of contemporary science; it also shows, on the other, that at the heart of this science is implicated a metatheoretical Möbius band – analogous to that which we identified above – which can only be neutralised by returning to the absolute 'Earth as ground' and to 'my body as centre' of all experience.[78]

---

[76] Ibid.

[77] 'Whether I walk or I stop, I have my body [*Leib*] as centre and around me bodies [*Körper*] at rest or in movement, and a ground without mobility' (Husserl, *Umsturz der kopernikanischen Lehre*, op.cit, 7).

As far as the question of anthropocentrism is concerned, it must first be noted that the eccentric dimension of experience conquered by Copernicus' revolution surely subtracts from the earth its privileged place within the cosmos, but that this effort is not sufficient to eliminate all anthropomorphism, the latter simply being pushed back to the confines of the universe in a sort of imaginary *absolute*, 'of the human body and face'. The Newtonian conception of absolute space as *sensorium dei* furnishes a proof of this marginal and phantasmatic persistence of the human form.[79] The most furious enemy of all anthropomorphism, Spinoza, offers another when he claims to ontologise an historical product of human reason – the deductive system of Euclidean geometry – in the eternal substance of divine Nature. Laplace's omniscient demon, who foresees the behaviour of the universe as if it were a Turing machine pre-programmed by a great evil engineer, represents a third.[80] In sum, it is as if anthropocentrism was only progressively eliminated from the contents of knowledge – or, more precisely, from the topologico-spatial structure of the universe – whereas it is reborn in a reinforced fashion in the specific form of the act of knowing. Why?

---

[78] 'If I now think of the Earth as of a body in motion, in order to so think it or, more generally, in order to think it as a body […] I need a ground to which to refer every experience of the body and thus also all experience of the being which remains at rest or in movement' (Husserl, *Umsturz der kopernikanischen Lehre,* op. cit., 6-7). But since science can never rejoin this new absolute ground – because every new ground will be but an extension of that originary ground which is, for humanity, the Earth: 'the Earth can just as little lose its sense of *primordial enduring*, the arche of the world, as my body [*Leib*] can lose its most singular sense of being a proper primordial body [*Urleib*] from which every body derives a part of its sense of being.' (Ibid., 15).

[79] This phenomena could be explained as follows: Since every relative movement comes to be seen as such in relation to an absolute – that is to say, in relation 'to a "body-ground", perceived as in a state of rest, a "body-ground" with which my corporeal soma is as one' (Husserl, *Umsturz der kopernikanischen Lehre*, op.cit., 5-6) – the (Copernican) subtraction of that originary ground which is the Earth provokes the theoretical production of new absolutes which necessarily function as phantasmatic 'body-grounds'.

To understand this point, we must first of all recall that the eccentric dimension of experience marks a radical rupture between the human modality of human experience and that of every other animal. The sensory experience of the sun which moves against an immobile terrestrial background is shared by human and animal alike.[81] On the contrary, what remains inaccessible to every other animal is the capacity to *transfer* its thought of the sensory and corporeal here-and-now into a time and a space which have not 'taken place'. In other words, qua exaptive and metaphorical being, obliged to pass through a series of

---

[80] This metaphorical displacement of the originary 'body-ground' might also be produced in a purely 'subjective' dimension. Kant's transcendental I – which claims to *unify* a shattered universe, which has lost its objective centre and which refuses all interference of God in science – might offer an example. The difficulties which contemporary neurobiological theories encounter in elaborating a theory of consciousness which presupposes no preconstituted identitary instance – cerebral homunculus or central processing unit – represent another. In short, once that absolute that is the human body, perceiving and acting against the background of the Earth, has been expelled from the system of reason and knowledge, it reappears in a sublimated and metaphorised form as a central instance of consciousness, or as a (quasi-intentional) sensor for information that is already inscribed – objectively as metaphorically – in nature.

[81] 'The gift of sensory experience is available only to motile creatures which, in rising from the ground, establish a position opposite to the ground and thereby gain a relation to objects qua objects within the open horizon of the world. In this truly fundamental situation, the senses serve men and animals first of all in their basic task of orienting them toward their environment. The primary frame of reference for our moto-sensorium is the earth and the firmament, resting in their own weight. Against this background, we actually see the sun, the moon, and the stars moving, and I daresay we see it correctly as far as seeing is concerned.' (Straus, 'The Expression of Thinking', op. cit., 282)

(intrasensorial) schemata and (linguistic) mediations ever more exempt from direct sensory contact with reality, man is in essence the eccentric animal; and it is indeed this eccentric dimension of experience which was conquered in systematic fashion by the Copernican revolution and the science that followed it.[82] Qua product of a specifically human modality of knowledge, science thus does not pursue a deanthropomorphisation of reality, but rather a process of progressive humanisation, one whose price is a kind of ontological loss of the world. The price we pay for the eccentric character of our experience is, in fact, according to some, the effective loss of that originary dimension of experience which we share with all other animals; loss of the world to which we accede through our senses and our bodies.[83]

---

[82] 'The Copernican system does not correct erroneous sensorial impressions; it transcends the realm of sensory experience. Though contemplated on earth, it is not visualized from the earth. The observer is transferred to Erehwon, to nowhere; he is removed from his terrestrial point of view and freed from its limitations. In sensory observation, bound to the actual situation, we are also limited by it; we see fragments only. The heliocentric system, however, puts together all the fragments. It considers not only sun, planets, and earth in one view of imagination; it comprehends the whole of their circuits. It comprises in one geometrical figure all the possible positions of the earth on its path around the sun, passed in the course of one full year. With the aid of a mathematical model, indifferent in its proportions to the natural conditions of place and time, size and weight, we break through the barriers of sensory experience.' (Ibid.)

[83] 'In sensory experience we are in direct contact with things; they stand before us and we before them. In thinking the relation is an indirect one; the noema mediates between the thinker and the target of his imagination. Conceptual thinking requires a radical *ekbasis* from any particular position. We may as well say that because man can perform such an *ekbasis* from the social and the physical environment, and finally from his own corporeal existence, he is able to think. The characteristic attitude of the thinker expresses this 'excarnation' – the price man must pay for his intellectual and spiritual achievements' (Ibid., 282-3)

The objective of this text, however, was to show that there exists a path which leads from the human body to the eccentric thinking of science (passing through the hand, the eye, the voice, right up to the linguistic and mathematical schemata, exempt from any sensorial *hic et nunc*); and indeed, also an inverse path which leads back from eccentric thought to an animal body, to a singular ontogenetic development, a path which we discover in the necessity of transferring into the world its communicative structure, whose traces science will continue to carry up to the very (hypothetical) 'end' of its journey. As opposed to Straus and the other thinkers who conceive this path as a sort of leap, rupture or originary loss of infantile or animal paradise, I hope to have shown that the modality of experience that is at the foundation of the Copernican revolution and of all of modern science does not produce any void or irreversible loss, but only an anxious errancy which finds in a singular type of animal body its quasi-transcendental biological condition of possibility. An errancy which, from this point onward, cannot be infinitely diluted, but which does possess limits which coincide with the contours traced by an incessant oscillation between our body and its Other, imaginary or real; between our thought and a Nature from which thought emerged and detached itself as if it found itself faced with an alterity; between our nature and that of a reality with which we are obliged ceaselessly to conduct a dialogue. In conclusion, in this way human errancy could also be a metaphor for a singular animal condition to which Nature would oblige us, so as to both distance us from and bring us closer to it.

Thinking Outside the Brain

Paul Humphreys

Philosophy is a naturally sceptical discipline. Limits on what can be known, constant doubts about our most cherished beliefs, impossibility theorems – such is the gloomy lot of a philosopher. Fortunately for those of us with a more constructive outlook, not all philosophical results are so pessimistic. Were John Stuart Mill alive today, he may well have questioned our political wisdom, but he would surely be envious of the growth in our scientific epistemology. Yet there is a group of constraints on knowledge that has seemed insurmountable. This group contains the *egocentric predicament*, the Ralph Barton Perry claim that each human can experience and know the world only from his or her individual psychological and perceptual perspective; its generalization, which we can call *the anthropocentric predicament*, the apparent fact that we can only experience and know the world from a specifically human perspective, one that is fixed in part by our peculiar evolutionary history; and the *linguistic determinism* position, the idea that the limits of language are the limits of thought. All of this pessimism is natural, most of it is well argued, and a great deal of it will be rendered irrelevant by developments in science. This essay will explain why.

THE GREAT HALL OF MIRRORS

Perhaps because of these constraints, contemporary epistemology continues to be saturated with anthropocentric views. Its subject matter, almost without exception, is human epistemology, based on a tradition stretching from the pre-Socratics, on through Descartes, and affecting even the philosophy of artificial intelligence, within which human cognition still serves as the most significant reference point. Consider just a few famous titles: John Locke's *Essay Concerning Human Understanding,* George Berkeley's *A Treatise Concerning the Principles of Human Knowledge*, David Hume's *A Treatise of Human Knowledge*, Thomas Reid's *Essays on the Intellectual Powers of Man*, and Bertrand Russell's *Human Knowledge: Its Scope and Limits.* Despite their respect for science, the logical positivists emphasized the centrality of human sensory experiences, Thomas Kuhn's paradigms were rooted in communities of human scientists, and Willard Quine's pragmatism leans heavily on the choices made by human language users. We humans do like to admire ourselves in the mirror of nature.

Variations on these constraints place limits on knowledge whether one is a realist or an anti-realist, a human or another species altogether. Were you to be a solipsist, the boundaries of your lonely little existence would be set by the modes of thought peculiar to you as a self-conceived human. Chimps, extra-terrestrials, cognitively-aware computers; all have their own versions of the three predicaments just mentioned. Or so we are told.

Empiricism – the position that all legitimate knowledge must ultimately be justified in terms of evidence gained through human sensory experience – is one version of the anthropocentric predicament, for if empiricism is true, what we can know is essentially limited to what is accessible through a set of biologically contingent devices. Indeed, the supposed conflict between realism and empiricism makes sense only from the perspective of humans, simply because for an empiricist the limits of knowable reality are set by the cognitive limitations of humans. Realism thus acquires an anthropocentric taint in claiming that there are things lying beyond the reach of the human senses and that there exists a mind-independent reality, if only because the senses and the minds involved are those of humans. From the perspective of different kinds of knowledge producers, such as scientific instruments and computers, the division between what is accessible to the human senses or to the human mind, and what is not, is, ironically, an artificial division. It is for reasons such as this that traditional empiricism passed its expiration date long ago.

A famous version of the anthropocentric predicament is Kant's view that we are doomed to represent the world using fixed conceptual frameworks that form a part of the human cognitive apparatus. Kant's own choices for the frameworks – such as Euclidean spatial representations and deterministic cause-effect relations – turned out to be ill-advised, but the basic insight is striking.

Advances in science and mathematics, especially the development of formalism in the mid to late nineteenth century and the accompanying construction of non-Euclidean geometries, led to a liberalization of Kant's original position. Many non-Euclidean geometries are far more difficult, if not impossible, to imagine visually than is Euclidean geometry, but they can be developed and understood through the use of formal mathematical theories. This use of formal theories to generate new concepts shows that intuitionism as a philosophy of mathematics, with its emphasis on the human mind, is too confining, and that formal theories offer the possibility of taking an objective stand about mathematics without committing oneself to Platonism.

In fact, a formalist outlook has been present in some areas of science almost from the outset. Whatever the real motions of the planets are, for Ptolemy they were understandable only through their representations in mathematical astronomy;[1] for Galileo, the book of Nature was written in mathematics; and the struggle to understand inertia and gravitation in the seventeenth century was resolved only by conceding that one had to grasp those concepts through the role they played in mathematical physics. We should not forget that the modern idea of inertia, the idea that a body could continue to move forever without a force to maintain its motion, is deeply counterintuitive to a species that requires water and air to survive. Scientists who were born and thrived in a viscosity-free space would find inertial motion perfectly natural.

---

[1] Although it must be said that Ptolemaic representations were driven primarily by Platonic concerns rather than by the attractions of formalism.

And so fixed psychological frameworks have been replaced by flexible theoretical frameworks. Yet humans still have to understand the concepts, such as sets, points, energy, and information, that are involved in these formal languages, and the ability to develop physical and mathematical intuitions about these concepts is highly prized. Moreover, sophisticated and profound as these theoretical frameworks are, the formal mathematical manipulations continued to be constrained by the a priori reasoning abilities of human mathematicians and scientists. It is within this context that linguistic determinism came to be seen as the new, inescapable, constraint. The languages remained languages of, by, and for the people.

THE INTERFACE PROBLEM

There are two things wrong with linguistic determinism. The first is that it is false. A famously pithy, *ex cathedra* statement of linguistic determinism is Wittgenstein's aphorism '*The limits of my language* mean the limits of my world'.[2] Empirical research has been cited both for and against linguistic determinism, but a recent study of two groups of Australian children speaking aboriginal languages shows that they can perform basic counting operations just as competently as English-speaking children, despite the indigenous languages lacking words for cardinal numbers.[3] For example, the children speaking only an aboriginal language were able, as effectively as English speaking children, to select the correct number of beads matching the number of taps made by two wooden blocks. The most plausible explanation for this success is that the aboriginal children possess the mental concept of a one-to-one correspondence, even though they cannot express that idea, or the associated number concepts, in their languages. Results such as these are important because, even if lacking the appropriate vocabulary is an insurmountable barrier in some areas, the fact that it is not so in others shows that humans can develop terms for mental concepts for which they have no current vocabulary.

---

[2] *Tractatus Logico-Philosophicus*, trans. D. F. Pears & B.F. McGuinness (London: Routledge and Kegan Paul, 1961), §5.6.

[3] B. Butterworth, R. Reeve, F. Reynolds, & D. Lloyd, 'Numerical thought with and without words: Evidence from indigenous Australian children', *Proceedings of the National Academy of Sciences* 105, 2008: 13179-13184.

In the light of this, here is a little thought experiment: Much emphasis has been placed on computational accounts of the mind. Instead, imagine that non-computational biologically-based cognitive devices have been developed, perhaps modeled on human brains, perhaps on a different basis. It is entirely possible that such devices would possess innate concepts, just as human brains have developed such concepts through evolution, with the difference that the artifacts' concepts would probably be radically different from ours. The task would then be to have the artificial cognitive devices communicate their conceptual frameworks, firstly to each other, and secondly to us. The first goal is easily achieved by ensuring that the new devices have identical biological structures. The second goal is considerably more difficult – and not just because human brains and the newer devices would have different structures.

We can call the general problem of inventing effective intermediaries between artifacts and human cognition the *interface problem.* The interface problem is a generalization of the issues that underlie the difficulties in reconciling empiricism and realism and it is always present when we access the humanly unobservable realm using scientific instruments. It has two aspects – the interface between the instrument and its target, and the interface between the instrument and humans. Solutions to both aspects have been developed for traditional scientific instruments but we now have to develop interfaces for an even more powerful set of tools: those of a purely automated computational science.

THE SUBURBS OF THE SENSES

Precisely when humans first extended the range of their native perceptual abilities is not known. The first recorded mention of magnifying glasses is by the Arabic scientist Alhazen in 1021, although naturally occurring magnifiers such as rock crystal have been used for at least three thousand years. Microscopes were developed in Europe in the late sixteenth century, closely followed by refracting telescopes. Those early instruments have led to an astonishing array of devices that includes scanning tunnelling microscopes, nuclear magnetic resonance imaging devices, automated gene sequencing machines and many, many others. Until recently we required the output of these devices to be directly accessible to us in the form of visual images, numerical data arrays, and so on. But no longer. The computational revolution that began in the 1940s has led to an extension of our a priori representational abilities that is even more profound than the perceptual extension afforded by scientific instruments because it fosters the automation of knowledge. Computer assisted mathematics, computer simulations, the automated processing of data by computers – each of these has the ability to construct knowledge encoded in categories and processes that we cannot currently understand. The trick is to see whether, by extending our conceptual resources, we can appreciate what the science developed by such automata would be like – and, in turn, to gain access to realms of reality unimaginable by humans.

A PAIR OF DISTINCTIONS

I begin with two distinctions. Call the current situation within which humans have to understand science that is carried out in part by machines, in part by humans, the *hybrid scenario*. Call the more extreme situation of a completely automated science the *automated scenario*. The distinction is important because, in the hybrid scenario, we cannot completely abstract from human cognitive abilities when we discuss representational and computational issues. In the automated scenario human capabilities are irrelevant. The second distinction concerns shifts in scientific methods. Thomas Kuhn famously described as 'scientific revolutions' the discontinuities in concepts and methods that occur as a result of a change in scientific paradigms, such as the replacement of classical mechanics by modern quantum theory. We can usefully draw a distinction between *replacement revolutions* and *emplacement revolutions*. Replacement revolutions are then the familiar Kuhnian variety in which an established way of doing science is overthrown and a different set of methods takes over. Emplacement revolutions occur when a new way of doing science is introduced which largely leaves in place the existing scientific framework and supplements it with distinctively new methods. The introduction of laboratory experimentation was an emplacement revolution in the sense that it did not lead to the demise of theory or of observation. So too was the explicit development of statistics in the late nineteenth and early twentieth centuries.

In that sense, the rise and permanent establishment of computational science in the last half-century constitutes an emplacement revolution. This is not to say that theory and experiment remain unaffected by computational approaches, because certain theoretical methods that used to be carried out 'by hand' have now been taken over by computational methods and many experiments are now computer assisted, but theory and experiment have not been abandoned. They are not considered scientifically unacceptable in the way that the replacement revolutions of Copernican theory over Ptolemaic theory, Newtonian theory over Cartesian theory, or Darwinian theory over gradualism resulted in the previous approaches becoming untenable.

It is because we are currently in the hybrid scenario that computational science constitutes an emplacement revolution. If the automated scenario comes about, it is an open question whether we shall then have a replacement revolution. The question is open because we do not yet know whether a radically new non-representational apparatus will be used by the automated methods and existing methods of pursuing science will be abandoned by humans. My prediction is that automated experiments will continue but that automated theory and simulations will take on currently unrecognizable forms. Fortunately, in the hybrid scenario we can partially grasp a computer's world view. So let us start with that.

THE VIEW FROM INSIDE THE CAR

Thomas Nagel's famous article 'What Is It Like To Be a Bat?' argued that there was something that it was like to be a bat, but that we, as humans, could never know what that experience was like.[4] Nagel deliberately chose a species that was so different from humans in the way that it experienced and represented the world that we cannot analogically infer from our own experiences to what the bat's world is like.[5] Contemporary computers have no phenomenological experiences, so there is no phenomenology to account for, but there is such a thing as what it is like to represent the world in the way that a computer does. So let us see if we can imagine what it would be like to gather information about the world from the perspective of a computational device. One important feature is that such devices will often have only a local and not a global perspective on a situation. You can easily appreciate such local perspectives by imagining that you are sitting in a car in rush-hour traffic. You can see the car in front, the car behind, and the cars on either side, but no further. There are simple rules you obey, such as not colliding with another car, moving when and only when there is space in front or to the side, not reversing, and so on. The perspective you have on the traffic is purely local – you have no global understanding of the traffic jam as a whole. That's why drivers in traffic jams are always asking

---

[4] See T. Nagel, 'What Is It Like to Be a Bat?', *Philosophical Review* 83 (1974), 435-50.

[5] It is also possible that bats do not represent anything to themselves; they just do batty things without using representations of the world.

'What on earth is going on up there?' And indeed, this local perspective is exactly the perspective that an artificial agent has in a computer simulation of a traffic jam.

Contrast this with one of the most significant abilities that we humans possess, the ability to take an external, global perspective on many situations.[6] A helicopter pilot flying over a traffic jam has, of course, taken advantage of a third spatial dimension to view the jam, but the pilot also has the essential ability to conceptualize the traffic jam as a whole – here's a two mile clogged segment, there's a slowly moving segment near the on-ramp, and so on. Developing this global cognitive ability is one of the most important human intellectual achievements and one that computers often lack. Playing the board game of *Go* requires a global perspective, more so even than playing chess, in part because *Go* is a territorial game, in part because no human can consider the consequences of all possible moves at any given stage of a game – nor, for that matter, can any existing computer. In a different way, mathematical proofs require a global strategy as well as an understanding of the local rules governing individual steps in the proof. That is why someone can understand each step in a proof and not understand the proof as a whole.

We can catch another glimpse of what it is like to be a computer by using the device of a cellular automaton. This is a particular kind of computer which in its two-dimensional form consists in a square array of cells, each cell being coloured either black or white. Time-steps between states of the automaton are discrete and at the next time-step, the colour of any given cell depends on just two things, the current colour of that cell and the current colours of the neighbouring cells. Once a rule for the transition between the current state and the next state has been specified, the cellular automaton has been completely specified. For example, one cellular automaton runs on the rule 'If the current state of the cell is black, three of its neighbours are black and the rest white, then turn the cell white; otherwise the cell is black at the next time step'. It is possible to represent the behaviour of many important systems in physics using cellular automata, but our example will be philosophical. A traditional metaphysical problem has concerned whether the principle called the identity of indiscernibles has any possible exceptions. The principle states that if the names 'a' and 'b' pick out entities with *exactly* the same properties, then 'a' and 'b' are just different names for the same thing. Put another way, the principle says that there cannot be two things with exactly the same properties. Various clever or exotic counter-examples to this principle have been considered, going back at least as far as Kant. Indeed, the entire subject matter of quantum statistics is based on the violation of this principle by quantum entities such as electrons and photons. Many of these examples are difficult to imagine, but here is one that needs no fancy physics. Note that the rule defining a given cellular automaton does not mention which of the neighbours are in a given state, only how many of them are in that state. So imagine yourself as a black cell within a cellular automaton, equipped with our exemplary rule. As such, you do not have the ability to distinguish neighbouring cells by their location. All you know is that three otherwise indistinguishable cells are black and five indistinguishable cells are white and each falls into the class of things you need to consider. So you need to dutifully change your state from black to white.[7] In such ways we can imaginatively project ourselves out of our familiar spatial world in which position distinguishes otherwise identical objects such as two mint copies of *Harry Potter and the Deathly Hallows* and project ourselves into a non-spatial, cellular automaton world within which there are indistinguishable 'things'. So, at least to some extent, we can project ourselves into the conceptual frame of a computer. The point of these examples is to show that, with the help of imagination – sometimes a little, sometimes a great deal – humans can come to understand alien modes of thought.

---

[6] From here on I shall use 'global' as a synonym for 'non-local'.

A different issue is whether a locally-situated observer can have evidence for the global state of a system. This move from a local to a global perspective is a special sort of inductive inference, and an agent located on a cell of a cellular automaton could not necessarily make that inference. There are at least two reasons for this. First, his cell may exhibit a limited variety of behaviour that does not permit the inference of the global state of the automaton. For example, his own cell and its neighbours may simply alternate between two states, thereby not providing enough information to infer how other cells are behaving. He would also not have access to the global initial state, and knowledge of this state is ordinarily required to predict future states of the entire cellular automaton. The second reason is that new predicates that apply to the global states, and that cannot be defined in terms of individual states, may have to be invented in order to make effective predictions. Aggregate properties such as averages are no problem, but to reclassify the shape of a hanging chain as a catenary requires creative judgment. Just as we sometimes cannot understand the local perspective of computers, so they often cannot understand our global perspectives.

---

[7] I am taking the neighbourhood to be the von Neumann neighbourhood, which consists in the eight vertical, horizontal, and diagonal neighbours of a given cell.

LIVING WITH INCOMPLETENESS

We have seen that humans can overcome the anthropocentric predicament. There is also evidence that we are not trapped inside a web of words. Freed of these constraints, we can gain glimpses of what kind of realism is tenable. Mathematical models extend our conceptual reach but neither Platonism nor formalism entails that humans should be able to grasp all of mathematics. There is precedent for that view in other areas: medieval discussions of the Ontological Argument held that claims to have a full understanding of God were necessarily false in addition to being blasphemous. So it is hardly news that formally identifiable concepts exist that lie forever beyond the reach of humans. Despite Gödel's famous insistence that the truth of certain mathematical results is directly accessible to humans even though not amenable to proof, the epistemology of Platonism has always been mysterious, and it requires a commitment to supernaturalism because abstract objects, in the sense in which Platonists take abstract objects, are not a part of the natural world. This is in contrast to the epistemology of formalism within which, even if humans cannot fully or even partially understand certain formal concepts, we can understand how a computer can construct those concepts and effectively use them to interact with an external world.

Clear-thinking realists recognize that knowledge of the external world will always be incomplete and that Kant bequeathed to us a chimera, an unattainable because unintelligible goal, that of knowing a thing-in-itself. The challenge that modern science presents to us is a different one, it is to develop methods by means of which we can grasp the extended realm of reality to which instrumentally based, computationally augmented science provides access.

BEYOND THE HUMAN PALE

Let me now put the principal philosophical novelty of these new scientific methods in the starkest possible way: Computational science introduces new issues into the philosophy of science because it uses methods that push humans away from the centre of the epistemological enterprise. In doing this, it is continuing a historical development that began with the use of clocks and compasses, as well as the optical telescope and microscope; but it is distinctively different in that it divorces reasoning, rather than perceptual tasks, from human cognitive capacities. There were historical ancestors of computational science, such as astrolabes and orreries, but their operations were essentially dependent upon human calculations.

For an increasing number of fields in science, an exclusively anthropocentric epistemology is inappropriate because there now exist superior, non-human epistemic authorities. We have been discussing a special case of the anthropocentric predicament, the problem of how we, as humans, can understand and evaluate computationally based scientific methods that transcend our own abilities and operate in ways that we cannot fully understand.

Once again, this predicament is not entirely new because many scientific instruments use representational intermediaries that must be tailored to human cognitive capacities. Within the hybrid scenario, the representational devices, which include simulations and computationally assisted instruments such as automated genome sequencing, are constructed to balance the needs of the computational tools and the human consumers.

And so I am interested in a question that is common to computational methods in science and to mathematics. Simply put, there are two parts to this question. The first and easier part is: Is it possible to legitimately expand the set of concepts used in these areas to include some that we as humans do not currently possess? The second, harder, part is: Could science or mathematics be carried out using concepts and techniques that are essentially beyond human understanding?

The first part is easy to answer because the expansion has already happened. As for the second question, the answer also seems obvious – science as an objective mode of inquiry transcends human limitations and there already exist instruments – radio telescopes, scanning tunneling microscopes, and many others – for which a human/instrument interface can be somewhat crudely constructed but is irrelevant to the operation of the instrument. In the computational realm, data-mining algorithms on massive data sets, the detailed computations underlying many condensed matter simulations, and many others – all proceed in realms far removed from human computational abilities. There are, of course, serious dangers associated with these methods such as flawed code, hidden logic errors, wrongly calibrated instruments, and a general inability to check the methods in detail. These are not fatal to the enterprise; rather, they require a thoughtful understanding of how these new methods work. It is with understanding the concepts involved that the most problematical aspect of the new science enters.

'IT'S A COMPUTATIONAL THING – YOU WOULDN'T UNDERSTAND.'

Science has a number of aims. Some of these, such as the prediction and control of natural events, have already been automated. Most of us have safely flown on aircraft controlled by automatic pilots; driven cars assembled in factories by robots; been cured of illnesses by pharmaceuticals, the molecular structures of which were predicted and isolated by automated processes; and used electricity generated by computer-controlled nuclear reactors. These examples are drawn from applied science, but automata also play an important role in pure science. In astrophysics, gravitational lenses have been discovered by automated computer processing of data from robotic telescopes; in biology, computer assisted shotgun gene sequencing allowed the mapping of the human genome to be completed in advance of the stated deadline. In mathematics, automated theorem provers have proved results that eluded human mathematicians, such as the theorem that all Robbins algebras are Boolean algebras.

Another aim of science, understanding, seems to be beyond the reach of automata. This deficit will not be a problem if you follow certain anti-realist traditions in the philosophy of science, such as instrumentalism, which deny that explanation and understanding are appropriate goals of science. We also know that in some other areas of activity, such as chess, computers have achieved many goals of the game, such as predicting an opponent's most likely move and winning the game, without any understanding at all. (Other goals, such as gaining an aesthetic pleasure from a beautifully executed series of moves, are absent). Nevertheless, within the hybrid scenario, humans have to understand the human/machine interface, and if the concepts on either side fail to match, problems will ensue. In particular, if machines cannot provide the appropriate global concepts, there will be a serious conceptual discontinuity at the interface.

What happens to understanding when we lack the appropriate concepts? Here is where things become interesting and allow us to address a hard question. Until now, I have not discussed the egocentric predicament – the claim that an agent can understand the world only from its own individualistic perspective. One aspect of this predicament is not as pressing for computers and instruments as it is for humans because, unlike humans, exact duplicates of individual computers and most other instruments exist. Thus, your laptop's digital camera has exactly the same perspective on the world, and representation of it, as does mine when we trade them. Objectivity as intersubjectivity is therefore easy to achieve with artifacts. But the egocentric predicament reappears within computer models where only local perspectives are available. We saw an example with cellular automata. Other examples arise in agent-based models. These use a set of methods that begin with a collection of objects, which can be individual humans that participate in economic exchanges, molecules in a gas, trees in a forest, companies in an economy, and so on. Rules for how these individual agents interact are provided, but what is not initially included is a representation of the state of the entire society, the gas, the forest, or the economy. That is, each agent has its own local perspective and initially there is no overarching theory of the entire system. Using the rules for interactions, the agents in the model are allowed to interact many times. If we are lucky, a pattern will emerge that is a property of the system as a whole. If we are lucky again, we humans will already have a concept that captures that pattern, such as the temperature in a gas, a fire in a forest, or a welfare function for the society. But what if we do not?

An ancient tradition in science and mathematics dating at least as far back as Euclid and used by luminaries such as René Descartes, Isaac Newton, David Hilbert, Bertrand Russell, John von Neumann, and Andrei Kolmogorov uses an axiomatized theory to capture the fundamental truths in domains such as geometry, classical mechanics, logic, and probability. In some cases, the axiomatization will be complete, in the sense that all truths about the subject matter can be derived from the axioms. An important feature of a complete axiomatization is thus that, in principle, everything about the subject matter can be understood by understanding the axioms. This axiomatic tradition is related to two other ideals of science, those of theoretical reduction and theoretical unification. In its most extreme but widely held form, reductionism holds that, at least in principle, all scientific theories can be derived from the theories of fundamental physics and in turn these fundamental theories unify physics. Put another way, fundamental physics is theoretically complete with respect to all other sciences.

A common feature of axiomatized theories, although one not often remarked upon, is that the necessary global predicates are either built into the axioms or can be defined in terms of concepts contained in the axioms. It is this that is not true of many agent-based models and this puts the agents in the situation of the agents with only a local perspective that we discussed earlier. Global patterns require global concepts and if we, or a machine, have no way of representing them, they will lie undiscovered. The absence of certain global predicates is thus a form of incompleteness in the theory and it calls into question the axiomatic approach as a general method for representing scientific knowledge.

The need to introduce new global concepts is widely recognized in various areas of science and it is one reason why a full reduction to fundamental physics is not possible. The method of coarse-graining in condensed matter physics foregoes a detailed description of the components of a system in favour of a higher-level description for the sake of predictive efficiency. The related area of effective field theories requires physical intuition to produce the higher level concepts that are used.

I have emphasized the role of global concepts here but it is with concepts in general that the most challenging current problems of computational science lie. Whether in the hybrid or the purely automated scenario, some way of generating new representations has to be found. Yet this very problem may in its turn be the result of a lingering anthropocentrism. For it rests on the view that science needs representations, and that representations must employ concepts. Perhaps, unlike us, computational devices need neither concepts nor representations to carry out science. Therein lies the most important moral of this essay. One lesson that Copernicus bequeathed to us, and one that we periodically ignore, is that humans should stop thinking of ourselves as the centre of the universe. If we draw the proper epistemological conclusion from that lesson, then instead of forcing epistemologically superior devices to fit their results to our limitations, we have to begin to learn how to understand on their own terms the discoveries that they make. This is a lesson that the philosophy of artificial intelligence, for one, has largely ignored.

A dominant theme of philosophy over the last two centuries has been the emphasis on concepts and descriptions as intermediaries between epistemological agents and the world. Yet some instruments and some computers confront reality non-conceptually, and the sooner we try to understand how they do it, the faster we shall learn. It will be here that we can, perhaps, finally penetrate the barriers that have stood between us and the rest of reality.

We are standing on the edge of an enormous, mist-shrouded plain from which tantalizing, partial knowledge is brought to us by surrogates. The mist parts, folds, and in places permanently retreats. It distorts sounds, renders the touch clammy, brings odd, faintly familiar smells, and perhaps even suggests that our tastes must change. To stand here and to decode these messages is enormously exciting, more so than it has been for a hundred years. It is time to grasp pieces of this strange new world.

Notes on Contributors and Acknowledgements

Julian Barbour originally planned to be an astrophysicist, but in the mid-1960s became fascinated by the foundations of dynamics. After completing a PhD at Cologne on alternative derivations of general relativity, he decided to become an independent researcher in order to avoid the publish-or-perish syndrome. For twenty-eight years he supported his family and research activities by translating Russian scientific journals. He collaborated for several years with Bruno Bertotti on the implementation of Mach's principle, on which he has authored or co-authored numerous papers. In 1989 his *Absolute or Relative Motion? Vol. 1, The Discovery of Dynamics* (Cambridge University Press) was published. In 1995 he co-edited the conference proceedings *Mach's Principle: From Newton's Bucket to Quantum Gravity* (Birkhauser), and in 1999 published *The End of Time* (Weidenfeld & Nicolson), written for scientists and lay readers, in which he argued that the quantum universe is likely to be static. Together with numerous appearances on radio and in TV programmes, this book has made him well known to members of the public interested in the foundations of science. He has recently been appointed a Visiting Professor in Physics at the University of Oxford. Many of his papers can be accessed via his website (http://www.platonia.com).

Nick Bostrom is co-founder (with David Pearce) of the World Transhumanist Association, co-founder (with James Hughes) of the Institute for Ethics and Emerging Technologies, Director of the Future of Humanity Institute at Oxford University, UK (http://www.fhi.ox.ac.uk), and author of *Anthropic Bias: Observation Selection Effects in Science and Philosophy* (Routledge, 2002). Many of his papers can be accessed online via his website (http://www.nickbostrom.com).

Gabriel Catren is Director of the project 'Savoir et Système' at the Collège International de Philosophie in Paris and invited researcher at the Centre de Recherche en Épistémologie Appliquée (École Polytechnique/CNRS).

Milan Ćirković is Senior Research Associate at the Astronomical Observatory of Belgrade and Assistant Professor of the Department of Physics at the University of Novi Sad in Serbia and Montenegro. His interests include astrobiology and SETI studies, the evolution of galaxies and baryonic dark matter, the philosophy of science (especially philosophy of cosmology and quantum mechanics), future studies (in particular related to existential risks and transhumanism), science fiction, and the history of the physical sciences. Milan is co-editor, with IEET Chair Nick Bostrom, of the 2008 volume *Global Catastrophic Risks* (Oxford University Press). Many of his papers can be accessed online via his website (http://www.aob.bg.ac.yu/~mcirkovic/).

Jack Cohen is an internationally-renowned reproductive biologist. He worked in the Zoology Department at Birmingham University for thirty years, and later in the Warwick University Mathematics Institute for five, where he was made Honorary Professor. He has published about 120 research papers. His books include *Living Embryos* (Pergamon, 1963, 1967, 1980), a classic textbook that sold more than 100,000 copies; *Reproduction* (Butterworth, 1977); *Spermatozoa: Antibodies and Infertility* (Blackwell, 1978), *The Privileged Ape* (Parthenon, 1989); (with Ian Stewart) *The Collapse of Chaos* (Penguin, 1994), *Figments of Reality (Cambridge University Press, 1997)* and *What Does a Martian Look Like* (Ebury, 2002); and (with Stewart and Terry Pratchett) the bestselling *Science of Discworld* trilogy (Ebury, 1999, 2003, 2005). He acts as a consultant to top science fiction authors (e.g. McCaffrey, Gerrold, Harrison, Niven, Pratchett) designing alien creatures and ecologies. He is frequently heard on BBC radio programmes, and has initiated and participated in the production of several TV programmes for the BBC, ITV and Channel 4. His hobbies include boomerang throwing and keeping strange animals (from *Hydra*s to mantis shrimps, and octopi to llamas).

Nigel Cooke is a British painter widely known for his minutely detailed, large-scale canvases in which numerous smaller narratives play out amongst larger, overarching ideas. In the last few years Cooke's critically acclaimed body of work has been exhibited in solo presentations at the Moderna Museet in Stockholm, the South London Gallery in London, the Modern Art Museum of Fort Worth in Texas and at Tate Britain. Cooke was born in Manchester in 1973, studied at The Royal College of Art from 1995-1997 and received his PhD from Goldsmiths in 2004. He has been represented by Stuart Shave/Modern Art since the gallery opened in 1998.

Iain Hamilton Grant is Senior Lecturer in Philosophy at the University of the West of England. He is the author of *Philosophies of Nature after Schelling* (Continuum, 2006) and of numerous articles on Kant and post-Kantian Idealism, philosophy of nature, philosophy of science and technology, and contemporary philosophy. He is currently working on a book entitled *Grounds and Powers*.

Alberto Gualandi holds doctorates in Philosophy in France and Italy, and is currently a researcher attached to the University of Bologna. He has published several works, including *Le problème de la vérité scientifique dans la philosophie française contemporaine. La rupture et l'événement* (L'Harmattan, 1998); *Deleuze* (Les Belles Lettres, 1998, 2003); *Lyotard* (Les Belles Lettres, 1999, 2004) and has edited several numbers of *Discipline filosofiche*: *L'uomo, un progetto incompiuto. Vol. 1. Significato e attualità dell'antropologia filosofica* (Quodlibet, 2002), *Vol. 2. Antropologia filosofica e contemporaneità* (2002), *L'epistemologia francese e il problema del «trascendentale storico»* (with A. Cavazzini, 2006), and *Logiche del vivente. Evoluzione, sviluppo e cognizione nell'epistemologia francese contemporanea* (with A. Cavazzini, forthcoming, 2009). His current interests are centred around the philosophy of biology, philosophical anthropology and phenomenological aesthesiology.

Paul Humphreys is Professor of Philosophy at the University of Virginia. Recent publications include *Extending Ourselves: Computational Science, Empiricism and Scientific Method* (Oxford, 2004) and *Emergence: Contemporary Readings in Philosophy and Science* (co-edited with Mark Bedau, MIT Press, 2008).

James Ladyman is Professor of Philosophy at the University of Bristol, and co-editor of *The British Journal for the Philosophy of Science* (of which he was previously assistant and deputy editor). He was the Honorary Secretary of The British Society for the Philosophy of Science from 2003 to 2007. He is the author of *Understanding Philosophy of Science* (Routledge, 2002) which received a *Choice Outstanding Academic Title Award*, and, with Don Ross, *Every Thing Must Go: Metaphysics Naturalized* (Oxford University Press, 2007). He is currently writing a textbook on the philosophy of physics. In 2005 he was awarded a *Philip Leverhulme* Prize. He has published many articles on the philosophy of science and the philosophy of physics, including recently the entry on Structural Realism in *The Stanford Encyclopaedia of Philosophy*.

Robin Mackay is founding editor of *Collapse*, translator of numerous articles and of Alain Badiou's *Number and Numbers* (Polity, 2007).

Thomas Metzinger is currently Professor of Theoretical Philosophy at the Johannes Gutenberg-Universität Mainz and an Adjunct Fellow at the Frankfurt Institute for Advanced Study. He is past president of the German Cognitive Science Society and a founding board member of the Association for the

Scientific Study of Consciousness. His focus of research lies in analytical philosophy of mind, philosophy of science and philosophical aspects of the neuro- and cognitive sciences, as well as connections between ethics, philosophy of mind and anthropology. He has edited two collections on consciousness, *Conscious Experience* (Imprint Academic, 1995) and *Neural Correlates of Consciousness* (MIT Press, 2000) and one major English monograph developing a comprehensive, interdisciplinary theory of consciousness, the phenomenal self, and the first-person perspective (*Being No One – The Self-Model Theory of Subjectivity*, MIT Press, 2003). His most recent book is *The Ego Tunnel: The Science of the Mind and the Myth of the Self* (Basic Books, 2009).

Carlo Rovelli is a member of the Institut Universitaire de France and Professor of Physics at the University of Marseille. He leads the quantum gravity research group at the Center for Theoretical Physics of Luminy. He was one of the originators of the 'loop' approach to quantum gravity, one of the main theoretical hypotheses for describing the quantum properties of space and time. He has received numerous awards, including the 1995 Xanthopoulos Award 'for his contribution to the physics of space and time'. He has published around two hundred scientific articles and the monograph *Quantum Gravity* (Cambridge University Press, 2004), as well as books for the wider public, such as *What is Time? What is Space?* (Di Renzo Editore, 2004) and *Anaximander of Miletus* (Dunot, forthcoming).

Martin Schönfeld is a philosopher of nature at the University of South Florida in Tampa, USA. He has written on enlightenment, environment, and China. He keeps a blog on accelerating climate change and edits a climate philosophy newsletter. He is editing topic issues on the heuristic potential of climate change for *Journal of Global Ethics* and *Essays in Philosophy*. He is the author of *The Philosophy of the Young Kant* (Oxford University Press, 2000) and 'Green Kant', in Pojman, ed., *Environmental Ethics* (2008), and is now writing a book on Kantian *klimasophia*.

Conrad Shawcross is a British artist. Having featured in the prestigious *New Contemporaries* in 2001, and *New Blood* at the Saatchi Gallery in 2004, he has since exhibited internationally. Currently living and working in New York as an International Fellow for the arts based organization Location One, in 2009 he will be returning to London to become the Centenary Artist in Residence at the Science Museum, and is currently also working a major permanent commission for the UK government. Recent awards include the Art and Work awards for best sculptural installation of 2007. He is represented by Victoria Miro Gallery in the UK.

Ian Stewart is an internationally-renowned mathematician and Professor of Mathematics at the University of Warwick, dividing his time equally between research into nonlinear dynamics and furthering public awareness of mathematics. His current interests focus on the dynamics of networks. He was born in 1945 and educated at Cambridge and Warwick; he is a Fellow of the Royal Society and has four honorary degrees. His books include *Does God Play Dice?* (Penguin, 1989), *Letters to a Young Mathematician* (Basic Books, 2006), *Why Beauty is Truth* (Basic Books, 2007), and most recently *Professor Stewart's Cabinet of Mathematical Curiosities* (Basic Books, 2009), as well as (with Jack Cohen) *The Collapse of Chaos* (Penguin, 1994), *Figments of Reality (Cambridge University Press, 1997)* and *What Does a Martian Look Like* (Ebury, 2002); and (with Cohen and Terry Pratchett) the bestselling *Science of Discworld* trilogy (Ebury, 1999, 2003, 2005). His awards include the Royal Society's Faraday Medal (1995), the IMA Gold Medal (2000), the AAAS Public Understanding of Science and Technology Award (2001), and the LMS/IMA Zeeman Medal (2008). He appears frequently on radio and television, and presented the 1997 Christmas Lectures for the BBC.

Keith Tyson is an artist who has won international acclaim for his work in many different media and reflecting diverse interests in science, philosophy and art history. Tyson has exhibited internationally, and was awarded the Turner Prize in 2002. He lives and works in London and is represented by Haunch of Venison. http://www.keithtyson.com/

VOLUME V

CONTRIBUTORS: **Julian Barbour, Nick Bostrom, Gabriel Catren, Milan Ćirković, Jack Cohen & Ian Stewart, Nigel Cooke, Iain Hamilton Grant, Alberto Gualandi, Paul Humphreys, Immanuel Kant, James Ladyman, Robin Mackay, Thomas Metzinger, Carlo Rovelli, Martin Schönfeld, Conrad Shawcross, Keith Tyson.**

Ever since Nicolaus Copernicus unmoored the Earth from its anchorage at the centre of the Universe and set it hurtling around the Sun, science has progressively uncovered the lineaments of an objective reality to which human experience stands as only the most superficial and attenuated of abstractions. **COLLAPSE V**, 'The Copernican Imperative', brings together some of the most intellectually-challenging contemporary work devoted to exploring the philosophical implications of this ever-widening gulf between the real and the intuitable from a variety of overlapping and complementary standpoints.

With articles by groundbreaking philosophers and scientists, in-depth interviews with prominent thinkers, and new work from contemporary artists, **COLLAPSE V** addresses the issues of the 'deanthropomorphisation' of reality initiated by the Copernican Revolution, the relation between philosophical (Kantian) and scientific 'Copernicanism', and the enduring chasm between the spontaneous image of reality bequeathed to us by evolution and that revealed by the sciences in the wake of Copernicus.

Editorial Introduction

Robin Mackay

As far as we know, philosophy, indeed thinking as such, happens only on one planet. In our previous volume, we examined the ways in which philosophical and scientific thought pursued a liberation from the local conditions of 'earthly thought', counteracting the limitations imposed by our terrestrial locale and the biological heredity that binds our cognition to it. In this volume, we turn our gaze back towards our home planet to ask how, as products of the Earth, philosophers, scientists and artists have attempted to encompass it in thought; and how the philosophical enterprise of thinking 'the whole' has been, and continues to be, determined by our belonging to the Earth.

There is a timely aspect to this inquiry: Whereas the optimism of the late twentieth century saw 'globalisation' become a byword for limitless expansion, our image of the global in the first decade of the twenty-first century was characterised instead by contraction, by a forced recognition that the increasing technological interconnection and ever-intensifying exploitation of the Earth by humans was exposing finite limits, economic and ecological, of the planet upon which their world-systems are imposed.

Much of the response to the ensuing crises has remained entrenched within nostalgic regret, emotional imprecation and moral imperative. In this volume we attempt to forego this panic response and instead to present a diverse selection of contributions which demonstrate that philosophy, science and contemporary art continue to address the condition of thinking on and of Earth in original and engaging manners.

We know that thinkers have long used the surface of the Earth as a rich source of metaphor: in so far as it seeks for secure 'ground' on which to place thought, geographic cartographic and geological metaphors are endemic to philosophy. But beyond this metaphorics, as **NICOLA MASCIANDARO** argues in his 'Becoming Spice: Commentary as Geophilosophy', the practice of philosophy itself can be seen as a continual process of 'worlding'.

Beginning with the failure of the 'philosophical flight' from the earthbound in Dante, Masciandaro argues that philosophy belongs not to the 'folly' of a vertically-oriented 'straight path' but to a 'circular and endless' movement on the surface of the earth. And for Masciandaro, who directs the project Glossator,[1] dedicated to a contemporary revivification of the practice of commentary, it is the latter that provides the key to understanding this endless movement: commentary as the continual production of knowledge, a practice that 'proceeds by staying'. Philosophy's aim 'to render actual its absoluteness', to enter into self-immanence – the 'Copernican' impulse to absolutise – only proceeds, according to Masciandaro, through commentary's continual 'dwelling on the problem'. He further sees this role of commentary as being encoded in spice, as a global commodity whose currency and commercial movement figures the production of understanding through continual differentiation and distribution. Thus, commentary is not a mere 'condiment', but figures a peripatetic wandering and returning that draws forth the immanence of what is, only by adding to it, by 'spicing' it and thereby 'bringing out' the mode in which it is *more* than it is. For Masciandaro, therefore, 'the *telos* of commentary, its far-off end, is *tellus*, what bears us'; thinking brings us back to a continually-differentiated Earth.

---

[1] See http://www.glossator.org/.

One significant modern attempt to create a philosophy that addresses the Earth system as an 'All' is **F. W. J. SCHELLING**'s *Naturphilosophie*, which sought to encompass within a single set of philosophical principles the production of nature and thought; of thought out of and as a part of nature. In Schelling's 1798 work, previously unavailable in translation, the philosopher revendicates the ancient theory of the 'World-Soul', entirely reconstructing it through the contemporary science of his time, which he supplements with the necessary speculative basis that will allow him to effect his grand synthesis. As **IAIN HAMILTON GRANT** tells us in his introduction to his new translation, Schelling's book must be understood as a bold experiment in systematically thinking 'the All': Not content with providing a transcendental account of thought's *a priori* determination of its object, Schelling attempts to ground this determination in a Nature conceived as a *prius*, the polarisation of whose primitive forces can be traced through all of natural organisation, conditioning even the consciousness through which they become manifest as concept.

The contemporary ecological crisis demands a (somewhat more modest) reframing of the task of conceiving systematically the 'All' of nature – the biosphere within which human beings are increasingly aware of their implication. We are all well acquainted with the dread auguries emerging from what the media generically refer to as 'scientists'; but this reception reveals little as to the difficulties that beset those tasked with making such projections.

Our interviews with **Stephen Emmott**, **Drew Purves**, **Rich Williams** and **Greg McInerny**, scientists working in Computational Ecology and Environmental Science at Microsoft's Research Laboratory in Cambridge, England, offer some insight into the contemporary stakes of ecological thought, revealing ecology as a science in a state of flux and renegotiation.

They describe how, combining empirical knowledge of the mechanisms of growth, evolution and competition with an arsenal of statistical and computational techniques, their virtual 'in-silico' world-systems – Purves talks of them as involving a selection from a 'universe of universes' – aim to refine hypotheses and constrain predictions regarding the effects of climate change. As the interviewees reveal, the challenges they face make necessary a 'new kind of science' in which the barriers between disciplines are being broken down, and the order of scientific research disrupted or reversed. Negotiating the fearsome task of creating, in Emmott's words, 'a precise, predictive science of complex natural systems' calls for a meticulous questioning of received truths, and a triage between abstraction, accuracy, and uncertainty, in a quest for a 'simplicity on the other side of complexity'. As Purves suggests, it is ecologists who are above all properly placed to give a 'high-level view'; but as we see in McInerny's description of his work, the indications of such a high-level view depend crucially on the selection of theoretical frameworks and on our understanding of low-level biological and genetic factors, shifts in the understanding of which can have radical consequences for prediction. In incorporating them into new computational models, Purves, McInerny and Williams have shown that the presence and interaction of these additional factors can crucially alter our understanding of global processes.

As well as exploring the details of the research underway, it was also important in these conversations to reflect on the predicament of the scientist called on to estimate the fate of the planet; a specialist whose area of research has been reinvigorated by the ecological crisis, but who must remain vigilant against overconfidence and oversimplification. Despite their optimism, the unanimous conclusion of our interviewees is that ecology remains a 'young science': a science already capable of providing an adumbration of the future of the biosphere, but which still faces a great many 'unknown unknowns'.

In addition, it emerges that this work is constrained on all sides by the contingencies of its history: dependent on legacy data and the choices made by those who preceded them, ecologists are involved in a continual reevaluation of their scientific and theoretical inheritance. Perhaps the most serious constraint, however, lies in the additional task of presenting their results to a concerned public. Struggling to be heard clearly amidst political manoeuvring, economic exigencies, and the evangelising of activists and conservationists, as Emmott remarks, ecology today must concern itself not only with theorisation and analysis, but also with clear communication of its point of view as a science.

As McInerny points out, 'activism' often reflects the uninterrogated prejudices and desires of those involved more than the state of scientific knowledge. **Timothy Morton**'s work in ecocriticism dissects the ways in which the narratives and aesthetics of 'environmentalism' remain captive to such unavowed assumptions. Morton's *Ecology Without Nature*,[2] which argued that the idea of 'Nature' is only ever an obstruction to ecological thinking, opened by making a heartfelt case for the importance of philosophical thinking and the creation of new concepts in order to prevent our sense of ecological emergency from precipitating a retreat into nostalgia and the safety of thinking 'Nature' as 'something over there'. In his article for **Collapse**, 'Thinking Ecology' – a preview of his forthcoming book *The Ecological Thought*[3] – Morton proceeds to pick apart the ideological attitudes, still in thrall to the Romantic view of 'Nature', that allow environmentalism, under cover of a naive sincerity, to avoid thinking ecological interdependence. As he argues, the latter thought is not to be attained through blithely asserting our 'community' with the denizens of nature. Simple denial of our own gaze, and the 'framing' it imposes on nature, is not an option: it amounts, as he argues, to the perpetuation of a 'beautiful soul syndrome'. Instead Morton invites us to experience the 'humiliation' of recognising our disturbing collective intimacy with 'life' as a

---

[2] *Ecology Without Nature: Rethinking Environmental Aesthetics* (Cambridge, Mass.: Harvard University Press, 2007)

[3] Cambridge, Mass.: Harvard University Press, forthcoming 2010.

'strange stranger', drawing us into a 'dark ecology' in which awareness, rather than implying a contemplative 'letting-be' of 'Nature', delivers a melancholy, ironic recognition that our very rendering of the 'crime scene' implies our necessary and constitutive implication in the crime.

This critique of the ideology of environmentalism is extended and dramatised by UK artist collective FIELDCLUB. Their work explores the humour that emerges in actually following self-sufficiency edicts 'on the ground'; and the irony that comes from raising the principles of ecology to the most general context imaginable. Underpinned by a theoretical position drawing on the long-forgotten neo-Gnostic lore of 'agrosophy',[4] FIELDCLUB remove ecology and the 'anthropic technosphere' from the parochial domain of environmental politics and replace it within the framework of a Bataillean 'solar economy'.

Their irony is not the cynical resignation of the city-dweller; for their work documents a continuing attempt to live 'off-grid', disconnected from public utilities and drawing as little on outside resources as possible. Much of the collective's work draws wryly on incidents in the day-to-day course of this experiment in living, small occurrences that never fail to blacken the name of Eden. This intimate engagement allows them to challenge the credo according to which just a little goodwill and a little less technology could enable humans to temper their depredations in favour of a more gentle and wholesome coexistence with nature.

FIELDCLUB's concern with this uneasy 'complicity' with other living beings leads precisely into what can be seen as assays into Morton's 'dark ecology'. To become close to nature, they demonstrate, is at the very least to repudiate the notion that the Earth is something unreservedly worthy of our admiration, and from which we can draw comforting meaning. The series of devices exhibited in FIELDCLUB's contribution to this volume intimate that man's relation to the soil, no matter how 'traditional' or 'simple', strips us of our 'beautiful soul' credentials and reminds us we must 'kill to live'; at the same time, they lampoon the efforts made through technological mediation to flee the 'scene of the crime'.

---

[4] See http://www.fieldclub.co.uk/texts.php

Evidently, any examination of the relation of thought to the Earth must address the way in which we dwell upon, thus transforming, its surface. **Owen Hatherley**'s project to rescue architectural modernism from the 'Ikea modernism' of 'light and airy' interior design belonging to the vacuous economic optimism of the late twentieth-century[5] leads him to the contention that, in restoring the links of modernism with its less palatable predecessors – such as the proto-brutalism of Hitler's Atlantic Wall – we reawaken a suppressed, but rich and provocative, historical lineage. Hatherley's analysis is inspired by Ballard's discovery of a 'warped modernism' in the structures of the Atlantic Wall. And as Hatherley's discussion implies, if we are to consider Ballard as a precursor to 'psychogeography', the latter must be understood in terms of *regression*, so that, as in Ballard's novels, in the contemplation of these (non)structures we experience an 'end-point of architecture': The enterprise of design and construction degenerates into an atavism where 'primal impulses and prehistoric building forms recur', but which paradoxically (as evidenced by Virilio's adaptation of this aesthetic for his brutalist church) also communicates with an impulse to the sacred. These 'instant ruins' thus tap into an architectural phylum which, actualised by a military 'science of compaction and impact', marries emergency with eternity.

---

[5] See Hatherley's *Militant Modernism* (London: Zer0 Books, 2009)

Hatherley traces the few instances in which this rich seam resurfaces in architecture, but as he observes, in an increasingly hygienically-conservative architectural climate, it now belongs more to speculative thinking and to the work of artists such as Nicholas Moulin. The suggestion that with more attention, it might fuel an 'apocalyptic pulp of our own time' brings to mind the fact that, of course, Ballard's apocalyptic *Drowned World* must be considered the first science-fictional treatment of climate change. From Ballard's reflections on these forgotten structures, Hatherley thus draws out a as-yet unrealised 'earth-philosophy' as remote from tree-hugging as Ikea is from the Atlantic Wall; one that, via the exigencies of total war, sets the chthonic forces of the inner earth flowing through the Apollonian veins of modernism.

Architect and theorist **Eyal Weizman** transports this immanence with the 'chthonic' into architectural practice: His project *Decolonizing Architecture* seeks to apply an 'ungrounding' process to spaces previously invested with colonialism, practicing 'design by destruction'. *DA* has evolved from Weizman's examination of the role that architecture has played in the Israeli occupation of Palestine; in our interview, he describes the way in which he sees architecture per se as interacting with the 'political architecture' of this occupation, and how the structure of the latter has entered into conceptual commerce with theory. Weizman's conception of 'forensic architecture', in seeking to read the nature of historical events through their material traces, implies a new articulation of 'forces and forms', wherein forms not only register the multiplicity of forces that bear upon them, but in turn become actors in this political 'forcefield'. We discuss the way in which this materialist-pluralist conception of politics demands a rethinking of the notions of responsibility, ideology, and resistance, and how *DA*'s processes of 'design by destruction' and 'ungrounding' seek to disrupt the temporalities according to which the very question of a 'solution' to the problem of occupation has been posed.

Discussing the in some cases hostile reception to this work, Weizman also describes how it has led him to reconsider the very function of theory in the context of global politics: The theoretical enterprise can only operate, he argues, through an engagement with actual protagonists, whose functional roles within twenty-first century conflict bring to light the new conceptual frameworks within which that conflict is being conducted. Thus, concepts are not 'in the head' but 'in the world', and only by affirming this embeddedness of theory – by forensically examining the material traces of specific sites, and by journalistically naming names – can theory become a weapon of resistance.

Weizman's examination of the bonds between architecture and the martial recoding and territorialization of the Earth is further developed in **Manabrata Guha**'s 'Introduction to SIMADology'. Surveying today's 'global security ecology' Guha suggests that its regime of thinking the relation of war to the Earth – inherited, as he suggests, from the 'father' of the theory of warfare, Clausewitz – fails to register the radical difference that terror-operations impose upon the martial landscape. What Guha calls the SIMAD – Singularly Intensive Mobile Agencity of Decay – disrupts the Clausewitzian paradigm, drawing war-machines into a 'chthonic battlespace' which they are constitutively incapable of navigating. Even within the new paradigms of warfare which seek to confront changing conditions through 'network' or 'swarm' paradigms, the weapons of 'surprise' and 'terror' are read in the terms of a political and martial imaginary whose inappropriate causal and economic principles doom them to become, ultimately, a component of the threat they aim to neutralise. Extending Reza Negarestani's analysis of 'hypercamouflage',[6] and through a critique of the conclusions of prominent contemporary theorists of war, Guha depicts terror-operations as effecting a transformation on the instrumentalised war-machine of the state, causing it to proliferate and morph uncontrollably as it confronts the chthonic forces against which it attempts to differentiate itself – forces that owe nothing to tellurian structures, and whose eruption can only be registered as having already taken place. In attempting to 'seal off the tellurian surface' from these terror-Events, Guha suggests, war-machines operating on the Clausewitzian model merely generate self-deceiving fictions – bringing about a 'process of ontological decay' whose nature is opaque to strategic thinking. Maintaining the state at a 'tipping point […] between self-destruction and absolute consolidation', the SIMAD thus becomes the co-ordinator of 'global security governance' and the 'biopolitical model of the post-modern state'.

Confronting this 'complicity of visions' and drawing on **Reza Negarestani**'s contribution to **Collapse IV**,[7]

---

[6] R. Negarestani, 'The Militarization of Peace: Absence of Terror or Terror of Absence?', **Collapse** I, 53-91.

[7] R. Negarestani, 'The Corpse Bride: Thinking with Nigredo', **Collapse IV**, 129-61.

Guha in closing declares that '[w]e are that which decays *and* the agents of decay. We are expressions of the terrifying envoiding chemistry of decay'. Negarestani's contribution to the present volume expands this theme into the analytic description of an 'architecture and politics of decay'. Excavating some of the more bizarre preoccupations of mediaeval thought, and tracing their influence on early-modern mathematics, Negarestani suggests that they offer us the formal basis for an 'architecture, mathesis and politics of decay'.

This mathesis, of which Negarestani finds 'the most refined expression' in politics, sees the interior ideal of a form not as an origin, but as emerging processually through its decay, in tandem with a production of exteriorised derivatives. Distancing his thesis from any nostalgic fetishising of ruins and insisting that it not only applies to superficially 'decayed' states but must be thought of as a general principle, Negarestani notes that a 'politics of decay' is disturbing precisely because – like Guha's SIMAD – it invokes a universal dynamic principle that undermines any claims to wholeness and wholesomeness.

Notably, Negarestani's argument also contains a confrontation with the nihilism expounded by Ray Brassier in his *Nihil Unbound*:[8] Science's evacuation of the realm of organic interiority into the exteriority of space, Negarestani suggests, does not take place without a 'twisting' in time and in space. His suggestion of a calculus of decay as 'mathematics with a chemical disposition or chemical revolution via mathematical distributions' problematises any straightforward vector of exteriorization, both in the realm of in/organic matter and in the history of thought, by locating both within a *humus* whose vermicular twisting can never fully be 'worked out'. In a parallel to his remarkable book *Cyclonopedia*, where the molten core of the Earth attests to its immanence with the sun – and again, recalling Guha's SIMAD – for Negarestani exteriority is already a chthonic 'insider'.

---

[8] R. Brassier, *Nihil Unbound: Enlightenment and Extinction* (Basingstoke: Palgrave Macmillan, 2007).

In his precise definition of this positive process of 'decay as a building process', Negarestani in fact provides the abstract key to the strange confluences not only in Hatherley, Weizman and Guha's analyses, but also in Masciandaro's account of the continual self-differentiation of knowledge. As Masciandaro reminds us, commentary's addressing of the earthly condition constitutes, not a resignation to the inescapable finitude of the text, but philosophy's very 'boldness', its 'monstrous' aspiration to continually deform, denature and multiply what it attends to, in a twisting wherein the poetic impulse rejoins with the philosophical imperative, the wandering on the Earth with the will to flight. Negarestani's turn towards those incorrigible commentators, the Scholastics, elicits the formal identity of his vermicular chemico-mathematics with this process of exegetical 'twisting'. Perhaps then Negarestani not only succeeds Schelling as 'the philosopher of the new chemistry' – albeit, as Iain Hamilton Grant has suggested, a 'chemistry of darkness' – but also presents us with a 'chemistry of (the history of) philosophy'.

Needless to say, the Earth, in our dealings with it and our navigations on it, exists for us not in 'immediate experience', but in coded form. The work of artists **Angela Detanico and Rafael Lain** examines the many ways in which the surface of the planet is coded, and their playful constructions explore the peculiar grammatologies that emerge once this stenography between the geographical and the symbolic is in place; its disorientations highlighting the faith we place in our mediated figure of the world, often mistaking the map for the territory.

Charles Avery's work returns to what has long been a favourite geographical trope for philosophy. At a certain point in his practice, Avery decided to locate all of his future work within an imaginary Island, whose locations, inhabitants and culture he continues to render beautifully in a variety of media – including text, as in the enigmatic travelogue *The Islanders: An Introduction*,[9] an 'epilogue' to which Avery contributes to this volume. In **Collapse V** one of Avery's maps accompanied cosmologist Milan Ćirković's discussion of the 'archipelago of habitability'.[10] Setting out from this pairing, **Robin Mackay**'s prefatory essay to our presentation of Avery's work seeks to locate the latter as a possible contemporary successor to a rich history of 'Philosophers' Islands'. As Mackay remarks, the nature of Avery's project demands that 'the work' and its significance be sought, not in any one of the exquisite pieces exhibited by Avery, but in the Island 'itself' – the (unfinished) structural whole that will bind them together.

Our volume closes with two contributions that in very different ways address this philosophical obsession with the island and with the ocean that surrounds it. **Gilles Grelet** presents us with a manifesto of refusal: the task of philosophy as conceived by Althusser and systematically diagnosed by François Laruelle's 'non-

---

10. M. Ćirković, 'Sailing the Archipelago', **Collapse V**, 292-329.

philosophy' – as a series of 'decisions' producing trenchant lines of demarcation that partition the ground of thought – is rejected. 'Ungrounding' himself by taking to the other, predominating element of the planet, with a boat as his 'theory-body', Grelet extols theory as 'world-less', indeed as 'a full-on attack on the world', an angelic thought whose 'crossings' operate without the territorial imperatives of the 'worldly'.

Renée Green's film 'Endless Dreams and Water Between', originally shown in 2009 as part of an installation at the National Maritime Museum in Greenwich, uses the island and its surroundings as the setting for an interrogation into the making of thought in-between four protagonists. Inconclusive, dreamlike and – recalling Masciandaro's opening contribution – both referential and peripatetic, Green's film, the script of which is presented here, concerns itself with the geophilosophical precipitation of thought, as four women driven by a curiosity about their own location and inclinations move toward a speculative coherence that the work preserves in a state of 'clear-obscurity'. The island, a 'non-location' which serves as a navigational point of reference, also allows its inhabitants those uninterrupted vistas for the imagination that have provided writers with (sometimes, as in the case of George Sands, ultimately disappointed) dreams of freedom. As suggested by Masciandaro, it is by 'staying', by contemplating their island locations, that Green's protagonists move towards a collective thinking that expands into the realms of the abstract only on the basis of their localisation and the contingency of their respective interests and circumstances.

Like Avery's, Green's work highlights shifting relations between fiction and fact, physical geography and imaginary geography, that govern our thinking of the Earth and the worlds we build upon it. They join the other contributions to this volume in demonstrating that 'Planet Earth' qua terrestrial entity or biosphere is but one among those many inextricable 'wholes'. Even new efforts at reconstructing it in scientific models are never entirely free from evolutions and selections of their own, from the contingencies of history, and from the legacy of its duality in thought as 'object and omnipresence'.

The bringing together of apparently divergent perspectives within this volume is, we must as ever insist, not merely whimsical. It aims to bring into view avenues of thought which run between them and which may lead to new spaces outside the rigid boundaries of disciplinarity. In our introduction, as in previous volumes, we hope to have indicated some of these; others it will be the reader's business (and, we hope, pleasure) to trace.

It seems appropriate in closing to reflect briefly on the coherence, not only of this particular volume, but of the project as a whole; a coherence which, as is appropriate for a journal of 'research and development', has slowly come to light only in the process of working on the series. Through the creation of these volumes, from the beginning deliberately and sincerely billed as an 'experiment', has emerged a curatorial model in which, rather than all of the contributions to a publication falling within a circumscribed discipline or subject, a broad theme allows contributions from diverse practitioners to form an overlapping chain or (adopting Timothy Morton's term) mesh, whose intermediate links span otherwise disparate elements. The hope is that this connectivity should reproduce itself in the broad audience that **Collapse** assembles; that the 'forced collaboration' operated within these pages should find its counterpart in a strange collectivity of readers who, drawn in by one or two contributions appropriate to their interests, find themselves unexpectedly befriended by writers and thinkers from entirely different 'mindsets'. This in turn suggests a model of the concept according to which the latter resides, not in an hierarchical structure of progressive generalisation (a structure which reproduces and is reproduced in institutional specialisation), but in transversal connections discovered, or produced, 'in the making'. Thanks to a growing network of contributors and readers, each volume brings with it such discoveries, so that its finished state bears but a faint resemblance to the terms of its initial conception.

If, in search of this conceptual consistency, we have traversed the abstractions of mathematics (Volume I), the emerging paradigms of Speculative Realism (Volumes II and III), the legacy of Deleuze (Volume III), the horrors of thought and the thinking of horror (Volume IV) and the Copernican Turn in its many guises (Volume V), only to come back 'down to Earth', it is an Earth which we no longer fully recognise, and which continues to offer numerous challenges – by turns urgent, melancholy, and twisted – to the thought it has given birth to.

We would like to conclude by thanking all of our contributors for their work and their patience in collaborating on this volume, and to our readers for their continued enthusiasm for this process of 'research and development'.

Robin Mackay,
Falmouth, January 2010.

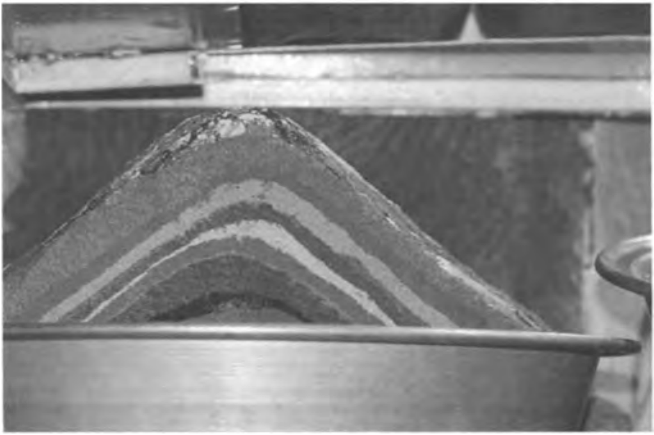
I. PREAMBLE



The twenty-sixth canto of Dante's *Inferno* voyages via the figure of Ulysses into the folly of philosophical *flight*: 'e volta nostra poppa nel mattino, / de' remi facemmo ali al folle volo' (26.124-5) [and turning our stern to the morning, we made our oars wings for the mad flight].[8] The deeper sense of the image is that oars are not wings, that such epistemological search, for what Ulysses calls 'l'esperïenza [...] del mondo sanza gente' (26.116-7), is fatally, merely earthbound. Ulysses's pursuit of 'virtute e canoscenza' (26.120) [virtue and knowledge] beyond the Pillars of Hercules ends in shipwreck within sight of the mountain Dante passes on his way beyond the stars: 'de la terra nova un turbo nacque / e percosse del legno il primo canto' (26.137-8) [from the new land a whirlwind rose and struck the forepart of the ship]. As accentuated by *canto* (prow), homonym with Dante's song-meaning word for the units of his poem, what is crucially at stake here is the boundary between philosophic and poetic modes of knowledge, the very boundary Dante's visionary text would overcome.[9] Ulysses's fate, recalled at the end of *Purgatorio*'s first canto ('Venimmo poi in sul lito deserto, / che mai non vide navicar sue acque / omo, che di tornar sia poscia esperto' (130-2) [we came on to the desert shore, that never saw any man navigate its waters who afterwards had experience of return]), also mirrors the opening impasse of the *Commedia*, where Dante is turned back from direct ascent of 'il dilettoso monte / ch'è principio e cagion di tutta gioia' (*Inferno* 1.77-8) [the delectable mountain, the source and cause of every happiness]. As commentators have noted, Ulysses's unidirectional demise refracts the abandoned prosimetric project of Dante's *Convivio*, which sets sail under the Aristotelian banner of knowledge=happiness.[10] The so-brief rejoicing of Ulysses and his men thus figures the impermanence and impropriety of such an easy equation, the impossibility of realising its truth by any straight path. The way to real knowledge passes through the underworld.[11] 'A te convien tenere altro vïaggio' (*Inferno* 1.91) [It behooves you to go by another way]. This way pursues a path that returns, one that begins by entering the earth.

---

[8] Dante Alighieri, *The Divine Comedy*, ed. C. S. Singleton (Princeton: Princeton University Press, 1973).

---

[9] 'convien saltar lo sacrato poema, / come chi trova suo cammin riciso [...]. non è pareggio da picciola barca / quel che fendendo va l'ardita prora, / né da nocchier ch'a sé medesimo parca' (*Paradiso* 23.62-9) [the sacred poem must needs make a leap, even as one who finds his way cut off [...]. It is no voyage for a little bark, this which my daring prow cleaves as it goes, nor for a pilot who would spare himself].

[10] The *Convivio* opens: 'As the Philosopher says at the beginning of the *First Philosophy*, all men by nature desire to know. The reason for this can be and is that each thing, impelled by a force provided by its own nature, inclines towards its own perfection. Since knowledge is the ultimate perfection of our soul, in which resides our ultimate happiness, we are all therefore by nature subject to a desire for it' (Dante Alighieri, *The Convivio*, trans. R. Lansing [New York: Garland, 1990], I.1).

The geophilosophical significance of Ulysses *folle volo*, newly seen from the sphere of the fixed stars with cartographic clarity as 'il varco / folle d'Ulisse' (*Paradiso* 27.82-3) [the mad track of Ulysses], lies in its contrast to the chthonic-celestial journey that surpasses it. Fleeing the place of human habitation, Ulysses remains ironically fixed to the earth's surface. Entering this place, Dante paradoxically reveals the heavenly beyond within the planet. The former movement is geometrically linear and terminal, the proper projection of the hero's finite concept of life as 'questa tanto picciola vigilia / d'i nostri sensi' (*Inferno* 26.114-5) [this so brief vigil of our senses]. The latter movement is geometrically circular and endless, the mode of the poet's impossible, always-already entering into eternity.[12] The former is terrestrial and territorializing.[13] The latter is spherical and peripatetic.

---

[11] 'The distance that separates Ulysses' point of shipwreck from the pilgrim's survival, or, for that matter, the *Convivio* from the *Purgatorio*, is measured by the descent into hell. This is literally true, according to the geography of the poem, and figuratively true as well, as the descent into the self, *intra nos*, is the prerequisite for the kind of transcendent knowledge that all men desire' (J. Freccero, *Dante: The Poetics of Conversion* [Cambridge, MA: Harvard University Press, 1988], 146).

[12] 'A l'alta fantasia qui mancò possa; / ma già volgeva il mio disio e 'l *velle*, / sì come rota ch'igualmente è mossa, / l'amor che move il sole e l'altre stelle' (*Paradiso* 33.142-5) [Here power failed the lofty phantasy; but already my desire and my will were revolved, like a wheel that is evenly moved, by the Love which moves the sun and the other stars].

[13] As indicated by the opening of Canto 26 of *Inferno*, which prefigures the terms of Ulysses's flight: 'Godi, Fiorenza, poi che se' sì grande / che per mare e per terra batti l'ali, / e per lo 'nferno tuo nome si spande! (1-3) [Rejoice, O Florence, since you are so great that over sea and land you beat your wings, and your name is spread through Hell!]

Yet there is continuity between the two, an umbral link that repeatedly foregrounds the latter as the realisation of the former.[14] Shadowing himself with Ulysses, Dante illuminates the geophilosophical trajectory of his journey. In particular, he uses Ulysses to reflect upon the coming-to-be of the *Commedia* out of and after the unfinished auto-commentarial project that precedes it. Dante's epic originates at the crossing of a threshold or crux defined by the intersection of the boundaries between poetry and philosophy, text and commentary, authorship and exegesis. These are the generic 'Pillars of Hercules' he crosses to become the 'first modern author' and anomalous object of an immediate commentary tradition.[15] The ongoing moment or engine of this becoming, the Ulysses-passing 'navicella del mio ingegno' (*Purgatorio* 1.2) [little bark of my genius] whereby Dante overleaps his own autoexegetical impasse, is the *Commedia*'s originary digression within the dark wood,[16] the pilgrim's turning back from direct philosophic ascent and admission into a subterranean path.

---

[14] As Singleton explains in his commentary on *Paradiso* 27.82-3, the poet's recollections of Ulysses coincide with threshold moments: 'the wayfaring Dante and the souls of those who pass Purgatory both complete successfully a fording which is denied Ulysses. And now, as the pilgrim is about to cross over from "the human to the divine, from time to eternity" (*Par.* XXXI, 37-8), his last glance earthwards takes in the "mad crossing" of Ulysses: again he stands on a "shore" that will forever be denied to the ancient hero.'

[15] See D. Parker, 'Interpreting the Commentary Tradition to the *Comedy*,' in *Dante: Contemporary Perspectives*, ed. A. A. Iannucci (Toronto: University of Toronto, 1997), 240-58; A. R. Ascoli, 'Auto-commentary: Dividing Dante,' chapter 4 of *Dante and the Making of A Modern Author* (Cambridge: Cambridge University Press, 2008), 175-226.

[16] 'Nel mezzo del cammin di nostra vita / mi ritrovai per una selva oscura, / che la diritta via era smarrita' (*Inferno* 1.1-3) [Midway in the journey of our life I found myself in a dark wood, for the straight way was lost].

I take this moment, which corresponds more precisely to the duration between the pilgrim's being turned back by the *lonza* (panther or leopard) and his meeting with his poet-guide Virgil (*Inferno* 1.31-60), as an invitation to think commentary's geophilosophical dimension, its constituting the *form* of philosophy's belonging to the earth. The question of this form is not only a problem of style and representation. The problem, as Dante's dramatisation of it reveals, concerns the very *how* of thought as a necessary relation between its content and its experience.[17] To succeed philosophically, to indeed arrive at and produce its truth, thought must realise or render actual its own absoluteness, the 'identity of identity and difference' with respect to itself. Thought must become the body it belongs to, a self-moving vehicle that carries its subject with it.[18] This imperative is beautifully presented in the *problemic* movement of the Dantean pilgrim who neither ascends above nor enters the earth, whose lower foot is always the firmer ("l piè fermo sempre era 'l più basso,' 1.30), and who is repeatedly turned back ('i' fui per ritornar più volte vòlto,' 1.36).

---

[17] A problem to which commentary in particular speaks: 'Western culture could be characterized as being irreparably driven between *Halacha* and *Aggada*, between *shari'at* and *haqīqat*, between subject matter and truth content. Any healing between these terms has become impossible (this, incidentally, is evident in the loss of the commentary and the gloss as creative forms) – at least since the demise of the medieval theory of the four meanings of writing. (This theory has nothing to do with the gratuitous exercise of four successive and distinct interpretations of a text; rather, it takes place among them, in *the living relationship* between subject matter and truth content' (G. Agamben, *Infancy and History: The Destruction of Experience*, trans. L. Heron [London: Verso, 1993], 160, my emphasis).

[18] Cf. Augustine's description of the way of arrival as what joins seeing and dwelling: 'discernerem atque distinguerem, quid interesset [...] inter videntes, quo eundum sit, nec videntes, qua, et viam ducentem ad beatificam patriam, non tantum cernendam sed habitandam' (*Confessions* [Cambridge, MA: Harvard University Press, 1950], 7.20) [I could discern and distinguish what difference there was between [...] those seeing where to go but not seeing how, and those seeing the way leading to the blessed homeland, which is not only to be discerned, but dwelt in].

Such a turning and circling motion which passes inside and across the philosophy/poetry boundary is exemplary of the commentarial impulse, an impulse which paradoxically proceeds by staying. Understood in these terms, the pilgrim's impasse, whereby he is caught in a motion that keeps him to the earth, is not simply the problem which the salvific production of the *Commedia* resolves, but its very labour.[19] Staying with the earth is the means of not remaining stuck on it, just as a boulderer proceeds by tenaciously experiencing the problem, staying *within* the encounter of the crux and passing through its difficulty (*ex-per-ientia*, 'coming out of and going through'). On this model, the geophilosopher is one who philosophically experiences rather than flees the earth, who passes through by remaining with it. Geophilosophical experience entails facing, more and more deeply, the fact of earth as the place of philosophy, and more profoundly, experiencing earth as facticity itself, the site of thought's passage to the absolute.[20] Commentary, the space of deictic and anagogic understanding, encodes this experience in the form of spice. As spice is a foundational term of terrestrial exploration, so commentary is the form of our geophilosophical becoming-spice, the practice whereby thought enters the earth and makes itself aromatic, that is, achieves the nature of a panther: 'This is an animal that is said to be parti-coloured, indeed colourful, and is extremely beautiful [*speciosissimum*] and gentle. [...] When it eats and is thus satiated, it hides in its cave and sleeps. But after three days it rises from sleep, and emits a great roar, and from its mouth comes forth a very sweet odour like all spices.'[21]

---

[19] The circular form of this productive impasse is elaborated in the pilgrim's later disclosure of the cord with he had hoped to capture the *lonza*: 'Io avea una corda intorno cinta, / e con essa pensai alcuna volta prender la lonza a la pelle dipinta' (*Inferno* 16.106-8) [I had a cord girt round me, and with it I once thought to take the gay-skinned leopard]. The cord is figurally associated with dialectic. See F. Masciandaro, 'La corda di Gerione e la cintura-serpente della Dialecttica,' *La conoscenza viva: Letture fenomenologiche da Dante a Machiavelli* (Ravenna: Longo, 1998), 45-54.

[20] 'We now know the location of the narrow passage through which thought is able to exit from itself – it is through facticity, and through facticity alone, that we are able to make our way towards the absolute' (Q. Meillassoux, *After Finitude: An Essay on the Necessity of Contingency*, trans. R. Brassier [London: Continuum, 2008], 63).

A more literal image of geophilosophic implication between commentary and spice is provided by Martin Behaim's annotated globe (Fig. 1), made in 1492 on the eve of the great European voyages of discovery. The globe presents the superimposition of two geometries: one, of commentary, a global ancient genre, as a kind of writing that in its very form seeks to sphericise a text, to surround it on all sides; the other, of spice, the original global commodity, as a kind of writing on the earth, a movement that marks and remarks relational networks. Next to the Spice Islands, Behaim provides a lengthy gloss detailing how 'spices pass through several hands in the islands of oriental India before they reach our country' that concludes as follows: 'Twelfthly, those who use the spices buy them of the retail dealers, and let the high customs duties profits be borne in mind which are levied twelve times upon the spices, the former amounting on each occasion to one pound out of every ten. From this it is to be understood that very great quantities must grow in the East and it need not be wondered that they are worth with us as much as gold.'[22] As the product of these geometries, the comment demonstrates interpretation as commerce, a laborious extraction of significance across time and space whose very process generates the value it apparently only translates, and exposes the inescapable spatiality and topology of understanding, the matrices of distance and desire that make for the pro-duction of meaning, its being brought into presence. It brings to mind the enigmatic lines, interpreted by Francis Bacon as prophesying the age of discovery and made to comment on the image of a ship passing the Pillars of Hercules in the frontispiece to his *Novum Organum* (1620): 'But you, Daniel, shut up the words, and seal the book, until the time of the end. Many shall run to and fro, and knowledge shall increase' (Daniel 12:4).[23] These may be read, phenomenologically rather than factually, as figuring exactly the earthly restlessness of understanding, its interpretive movement *around* that draws forth from what cannot be penetrated. Between the sealing of the text and the increase of knowledge is established the

[21] W. B. Clark, *A Medieval Book of Beasts: The Second-Family Bestiary: Commentary, Art, Text and Translation* (Rochester, NY: Boydell & Brewer, 2006), 123. Given Dante's emphasis on the beauty of the *lonza*, this is very likely the animal he has in mind, although the determination of its species 'seems next to impossible' (R. T. Holbrook, *Dante and the Animal Kingdom* [New York: Columbia University Press, 1902], 95) and is 'another of the *Comedy*'s little mysteries likely to remain unsolved' (Robert Hollander, commentary on *Inferno* 1.32-54, Dartmouth Dante Project <http://dante.dartmouth.edu>). More importantly, Dante's *lonza* is thus itself both figure and instance of the production of commentary's perfect object, something that generates unending commentary via the fact that it cannot be said or explained, only shown or indicated. Fulfilling the relation to *spice*, such an object is *special*: 'The *species* of each thing is its visibility, that is, its pure intelligibility. A being is special it if coincides with its own becoming visible, with its own revelation' (G. Agamben, *Profanations*, trans. J. Fort [New York: Zone, 2007], 57).

[23] 'And this proficience in navigation and discoveries may plant also an expectation of the further proficience and augmentation of all sciences; because it may seem they are ordained by God to be coevals, that is, to meet in one age. For so the prophet Daniel speaking of the latter times fortelleth, "Plurimi pertransibunt, et multiplex erit scientia': as if the openness and through passage of the world and the increase of knowledge were appointed to be in the same ages' (Francis Bacon, *The Advancement of Learning*, 2.10, cited from *Francis Bacon: The Major Works*, ed. B. Vickers [Oxford: Oxford University Press, 2002], 184).

surface over which understanding moves, a surface that is planetary, in the sense of enclosing what it contains. This is in an essential way the movement of philosophy, or rather philosophy itself as movement, 'the urge,' in Novalis's optimal topological definition, 'to be at home everywhere.'[24] For the practice of this restless urge also moves as over the surface of a whole, *as if movement itself would be relocated* and made the omnipresent term of equation between anywhere and everywhere. Such an equation is present in Heidegger's call to 'practice planetary thinking along a stretch of the road, be it ever so short,' which locates the global in a local path, the universality of thinking in the grounded practice (figural and/or literal) of walking where one is.[25] The movement of philosophy is thus not the means to, but precisely a freedom from destination, a *peri-patos* or around-walking that realises itself as processual and gerundive. 'Philosophy is philosophizing.'[26]

Tracing the movement of philosophy in these terms, as grounded in a movement of being that is unmistakably earthly and planetary, intersects with two essential features of commentary and geophilosophy that my exploration will pay particular attention to: digression and immanence, respectively. Digression belongs to commentary with respect to its 'go-and-stop' structure, its pausing of the text so as to move tangentially from it in any direction, but never so far or long as to prevent or forget returning.[27] The place of digression is the margin, the space into which commentary moves simultaneously away from, toward, more deeply into, and far beyond its text. The digression of commentary is not aimless or arbitrary, not merely wayward or adjacent. It is rather a wandering at once in and against the gravity of its return, like hunting or gathering *along the way*. Immanence belongs to geophilosophy, in all of its permutations and senses, as philosophy oriented to Earth, this earth, as the here-and-now place of its origin and space of its truth or realisation. Geophilosophy, above all via Nietzsche and Deleuze and Guattari, who established the term in the former ('Nietszche founded geophilosophy'), embraces the experiential, phenomenological fact of the absence of a transcendental outside and the rootedness of thinking in earth. 'There is no outside!' says Zarathustra, and the animals reply, 'In every Instant being begins; round every Here rolls the ball. There. The middle is everywhere. Crooked is the path of eternity.'[28] 'Thinking is neither a line drawn between subject and object nor a revolving of one around the other. Rather, thinking takes place in the relationship of territory and earth,' say Deleuze and Guattari.[29] Or, as Diane Chisholm explicates, 'The prefix *geo* does not signify a specialized branch of philosophy; it signals, rather, the *topos,* or the *now here,* of philosophical inquiry in place of a transcendental metaphysics that believes itself above being placeable, abstractly nowhere and universally everywhere.'[30] Geophilosophy's characteristic discursive ambivalence or confusion regarding the distinction between the literal earth and earth-as-metaphor, encapsulated in its Nietzschean phrasal cornerstone 'the meaning of the earth' [*Sinn der Erde*] and erroneously dissected by academic commentary, is part and parcel of its investment in immanence. The earth is the present object par excellence that can never be approached from distinctions between metaphorical and literal, figure and ground. Earth is so deeply present that its meaning is always falling back into earth 'itself.' Earth is 'too much with us,' as Wordsworth says of 'the world,' the *saeculum* of human work and worry, longing for a proportional belonging to the earth that world occludes. But it is exactly the combination of the earth's phenomenal unboundedness as object and omnipresence as fact that constitutes its inevitable diurnal occlusion, its constantly being forgotten via its very presence. So Heidegger grasps earth by defining it as closed and closing on itself: 'The earth appears openly cleared as itself only when it is perceived and preserved as that which is by nature undisclosable, that which shrinks from every disclosure and constantly keeps itself closed up [...] The earth is essentially self-secluding.

[27] 'Between the seemingly unavoidable and somehow joyful drive of commentary toward *copia* and commentators' obligations to show that their work is task oriented [...] between an aesthetics of exuberance and an aesthetics of streamlined reader functionality, commentators tend to develop a specific rhythm that one could perhaps characterize as "go-and-stop". On the one hand, they certainly want the user to appreciate the *copia* of the knowledge offered, but on the other hand, they hardly ever forget to insist on the rigorous functionality of their commentary, as if they anticipated protests of readers who would get lost in the meandering cross-references of the text on the margin.' To set forth the earth means to bring it into the Open as the self-secluding.'[31] Earthly immanence (from *in manere*, to remain within) is the remaining-within-itself whereby earth always remains within, is immanent to, world, the mode of its being that makes it always here. Earthly immanence is thus the counterpart of the presence of space, as that which everything always remains within. Earth is proportional to space, the chthonic to the khoral, which always remains without: 'And there is a third nature, which is space [*chōra*] and is eternal, and admits not of destruction and provides a home for all created things, and is apprehended when all sense is absent, by a kind of spurious reason, and is hardly real – which we, beholding as in a dream, say of all existence that it must of necessity be in some place and occupy a space.'[32] In short, space is to the sky as earth is to the ground. Earth and space are the twin dimensions where the boundary between the topological and the spatial totally breaks down. In one direction, space, embodied in the sky, gives way to absolute place, Plato's imperceptible container where everything must be. In another direction, place, embodied in the ground, gives way to absolute space, the abyss whose bowels Nietzsche esteems. In the neighbourhood of their mutual extremity, each becomes the other. And in the region of their most proximate differentiation, there is world (ground-sky), the mutually disclosing relation of earth and space that Heidegger calls the Open and feared technology to be closing.[33]

[33] Keith Tester comments on Heidegger's fear upon seeing photos from the moon: 'The photographs implied a containment of the meanings of the earth even as they also implied a freedom of humanity [...] from their natural home. But in that

Commentary is geophilosophical in the sense of being a movement that produces the immanence of the earth both formally and actually. Formally, commentary makes of a text, its earth, an *orbis*, a round world, by bringing text into the space around it. A dwelling in and on the text, commentary accords with Heidegger's explication of work as a dialectic of earth and world: 'Upon the earth and in it, historical man grounds his dwelling in the world. In setting up a world, the work sets forth the earth [...]. The work moves the earth itself into the Open of a world and keeps it there. *The work lets the earth be an earth*.'[34] Commentary likewise does not break its text, but preserves its integrity, shaping itself to it even in the midst of digging through it interlinearly and dwarfing, dominating it circumferentially. Something of the phenomenal earthiness of this complex relation is captured by our tendency to speak both of footnotes as *mines* and of *mining* footnotes. Commentary lets the text be a text and furthermore brings it into the open as self-secluding in the sense of presenting itself, not as some transparent medium for seeing behind or underneath it, but as *further* text. 'What [...] hermeneutic topologies of the below and the behind share,' says Gumbrecht, 'is a categorical – not to say dramatic – distinction between a level of primary perception and an always 'hidden' level of meaning and intentionality [...] In contrast, commentaries do not aim at a level 'below,' 'behind,' or even 'beyond' the textual surface, but commentators nevertheless do not see texts 'from above' or from that famous 'distance' that we so

---

containment, the photographs also made the earth a problem to be dealt with; an opportunity to be exploited, a standing reserve waiting for animation by the designs and desires of humanity through technology' (*The Inhuman Condition* [London: Routledge, 1995], 3).

34. Heidegger, 'The Origin of the Work of Art,' 46.

readily associate with objectivity. We expect commentaries [...] rather to be "lateral" in relation to their texts of reference, and we want commentators to position themselves in "contiguity" not so much with an author but with the text in question. It is this contiguity between the commentator's text and the text on which to comment that explains why the material form of the commentary depends on and has to adapt to the material form of the commented-on text.'[35] Yet, it is absolutely necessary to add (else the deep *dialectical* relation between text and commentary might be lost), that commentary's topological contiguity with its text does not delimit its interpretive, archaeological function, but rather institutes it as realised and to-be-realised in the text itself and our being before it. In other words, commentary is an immanent geo-graphy, an inscriptional earth-writing that continuously asserts by its very movement that its truth belongs *here* in the most palpable and factical sense, that it is *written into* the place of reader and text, as exemplified by the formal continuities between glossing and graffiti. This more complex relation between commentary and text, the movement, neither orthodox nor subversive, whereby commentary keeps to and maintains the surface of its text by perforating it, is present within Reza Negarestani's concept of Hidden Writings: 'Hidden Writing produces [...] positive disintegration, or more accurately collectivization of one author (voice) or an authorial elite, and its transformation to an untraceable shady collective of writers, a crowd [...] So-called hermeneutic rigor follows the logic of textual stratification, and can be achieved by hermeneutical tools corresponding to the layering order of its text. But the subsurface life of Hidden Writing is not the object of layers and interpretation; it can only be exhumed by distorting the structure of the book or the surface plot [...] To interact with Hidden Writings, one must persistently continue and contribute to the writing process of the book.'[36] Commentary constitutes a structure of understanding and experience, i.e. consciousness, that opens world to earth. It is writing's way of staying original, in ever-new nearness to its earthly origins, in productive proximity to the fact that all writing is only on the earth. The *telos* of commentary, its far-off end, is *tellus*, what bears us. 'Turn it and turn it again for everything is in it; and contemplate it and grow gray and old over it and stir not from it' (Aboth 5.22). What the Talmudic commentator here says of the Torah is sayable of the earth.[37]

---

[35] Gumbrecht, *The Powers of Philology*, 43-4.

Understanding commentary as geophilosophy, then, will involve understanding the relation between digression and immanence, as when two people, walking in conversation, stop walking and face each other. Or as when the Phoenix, in order to re-become itself, departs from her home, the blissful enclosure of Paradise, and seeks 'hunc orbem, mors ubi regna tenet' [this circular world where death rules].[38]

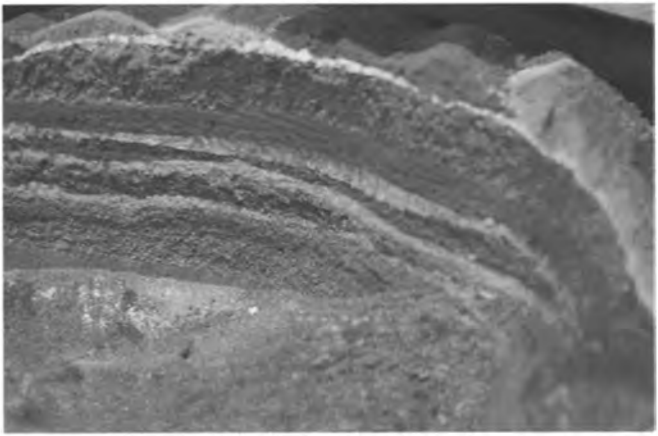
[36] R. Negarestani, *Cyclonopedia: Complicity with Anonymous Materials* (Melbourne: Re.Press, 2008), 62.

[37] Richard A. Cohen similarly identifies the 'concrete and productive integrity of spirit and matter' as a chief characteristic of (Levinasian) exegesis: 'Letters give rise to spirit, call for commentary, and spirit is rooted in letters, in a textual richness that is one of the marks of sacred literature, or literature taken in a sacred sense [...]. To fly with a text, to be inspired by it and discover its inspiration, requires not that one have wings, that one hover above it. Rather, it requires that one's feet be firmly planted on the earth, in touch with the concrete, never losing sight of a properly human dignity' (*Ethics, Exegesis and Philosophy: Interpretation After Levinas* [West Nyack, NY: Cambridge University Press, 2001], 247).

[38] Lactantius, *De Ave Phoenice*, ed. M. C. FitzPatrick (Philadelphia: University of Pennsylvania, 1933), line 64.

Here she encloses herself in a nest of spices, burns in her own flame, and is reborn. On the way back home, she carries in her claws the remains of her own body, mixed with balsam, myrrh, and Sabean frankincense, which she 'in formam conglobat ore pio' [forms with loving mouth into a globe].[39]

II. THE SPICE MUST FLOW



That spice has in fact been used to conceptualise commentary exemplifies one of its essential functions: to confound distinctions between utility and pleasure, necessity and luxury, food and flavor, literal and figural. In the Talmudic tractacte *Masekhet Soferim*, which deals with regulations concerning the preparation and study of the holy books, it is stated, 'The Torah is like salt, the Mishnah like pepper, the Gemara like spices.

---

[39] Lactantius, *De Ave Phoenice*, line 120.

The world cannot exist without salt, without pepper, or without spices. So also the world cannot exist without the Scriptures, and the Mishna, and the Gemara' (15.8). The evident purpose of the comparison is to articulate simultaneously the shared absolute necessity of all three texts and the superior value of the commentaries, in keeping with a reverence expressed more extremely elsewhere in the Talmud: 'He who only occupies himself with the study of the Torah is as if he had no God' ('Abodah Zarah 17b). Logically, the comparison produces a kind of ambivalence-without-ambivalence with regard to their relative values, so that the Gemara (commentaries on the Mishna, the written oral Law which, by a proportional logic, both expounds and is esteemed as equiprimordial with the Torah), are identified as more valuable than the value that grounds them. Commentary-as-spice is not merely an authoritative supplement to revealed scripture, not a condiment, but something that actually holds the essence of revelation as living process. Or as Gershom Scholem explains, in fortuitously tellurian terms: 'The Biblical scholar perceives revelation not as a unique and clearly delineated occurrence, but rather as a phenomenon of eternal fruitfulness to be unearthed and examined [...] Out of the religious tradition they bring forth something entirely new, something that itself commands religious dignity: commentary.'[40] This is commentary's ex-uberance, the way it bears forth a text's unending abundance, the durable newness of its sempiternal self-difference, the perfect plenitude of its unfinishing futility, in other words, a text's *continuing being*, its staying itself by always being other and more than itself.

---

[40] G. G. Scholem, 'Tradition and Commentary as Religious Categories in Judaism,' in *Understanding Jewish Theology: Classical Issues and Modern Perspectives*, ed. J. Neusner (New York: Ktav Publishing, 1973), 46-7.

'"Futility." [says Dr. Yueh to Lady Jessica] He glanced at her. "Can you remember your first taste of spice?" "It tasted like cinnamon." "But never the twice the same," he said. "It's like life – it presents a different face each time you take it. [...] And, like life, never to be truly synthesized."'[41] Commentary-as-spice thus upholds commentary as more *text* than the text it comments on, in a mysterious manner than both destroys and leaves intact the commentary/text distinction. Or, commentary embodies, not simply the relation of reader to text, but the relation whereby the text is itself. It is an externalisation of the existential medium whereby it is what it is, its essence or being. This accords with a proportional Talmudic passage which makes the ambivalence-without-ambivalence logic explicit: 'They who occupy themselves with the Bible [alone] are but of indifferent merit; with Mishnah, are indeed meritorious, and are rewarded for it; with Gemara – there can be nothing more meritorious; yet run always to the Mishnah more than to the Gemara' (Baba Mezia 33a). In other words, commentary materialises the movement, the flow of the text that makes it more than itself. And this *more*, this thing that is not a thing that makes all the difference, is spice. Commentary belongs to its text paradoxically as a property at once incommensurable and identical with its substance. In the graded terms of the comparison, such paradox is held within the aspecificity of the category of spice, the way it is both genus and species, such that spice simultaneously includes, exceeds, and is one of several among salt and pepper. With regard to spice's mixed resonances with the dimensions of pleasure and value, the metaphor may be understood as signaling that commentary is luxury as the perfection of necessity, the fruition of an essential textual value, or that commentary embodies the value of the value of the text, the earthly sublime or beyond *within* the text that makes it meaningful in the first place. Accordingly, talmudist Rabbi Hanina claimed that 'were the Torah, God forbid, to be forgotten in Israel, I would restore it by means of my dialectical arguments [*pilpuli*]' (*Baba Metzia*, 85b).[42] Wondrously, *pilpul* registers at once with round movement, hermeneutic dialectics, and spice. Jeffrey Rubenstein explains: 'Although literally meaning "turn from side to side", hence "search, examine, investigate", *pilpul* was derived by the Bavli from "pepper" (*pilpel*) and refers to intellectual sharpness and acumen. The term seems to be applied to a range of activity, including reasoning, interpreting and discussion, and need not always refer to sharpness in dialectics per se.'[43] *Pilpul*, glossed by Daniel Boyarin as the dialectical 'logic of commentary,' thus denotes the very *movement* of commentary's becoming, the roundabout way it enters into vital relation with the text as its own event.[44] 'Suspending time and space,' says Sander Gilman, '[*pilpul*] confronts the opinions of all authority, seeking the moment of resolution hidden within seemingly contradictory positions.'[45]

---

[41] Frank Herbert, *Dune*, 64.

The place of commentary is the space of spice. The sense of this is fulfilled by understanding spice as flow, currency, a travelling thing that does not leave its site of origin, something whose aromatic ability to permeate what is proximate to it, to have always already permeated it, marks it as not a *thing* at all, something not bounded by time and space. Spice as the figure of commentary's hermeneutic *location* of meaning as a center, the turning movement that reveals and re-reveals a text's heart, also coordinates with the identification of spices with Eden as the mythic, lost, metaphysical center of the world. As Milton writes of Satan's approach to Eden, 'now gentle gales / Fanning their odiferous wings dispense / Native perfumes, and whisper whence they stole / Those balmy spoils' (*Paradise Lost*, 4.156-9). Just as the alar movement of these lines destroys the distinction between breeze and scent, so not only spice's aroma but spice itself *is* what it is *of*. Spice is the substance of the *topological* filling of space, a fundamentally spherical phenomenon whose pluridimensionality defines it as the olfactory analogue to the ancient definition of God as a sphere whose center is everywhere and circumference nowhere. Accordingly, when a thirteenth-century Beguine named Sybil sought to demonstrate to her community the fact of her conversations with angels, she strewed, or more properly glossed, her house with spices.[46] And in the *Zohar*, the height of mystical vision, which intersects with the cabalist's intercourse with his wife on the midnight of the Sabbath, 'the point in time outside of time when God, attracted by their devotion, likes to visit them,' happens through the saturating medium of spice: 'These souls are there bathed in the spices of Paradise, and behold all that is within their capacity to behold.'[47]

Commentary-as-spice shows commentary as the savour of the significance of text, the actual phenomenal third thing between reader and text, subject and object, that exceeds both in a manner correlative to Aristotle's definition of tragedy as mimesis in 'spiced language' [*hêdusmenôi logôi*] (*Poetics*, 1449b25) – a definition which follows not condiment-logic but the ancient understanding of spice as the very potential of the edible: 'For when salts and seasonings [*hêdusmata*] generally are combined with a food,' says Alexander of Aphrodisias in his commentary on Aristotle's *Meteorology*, 'out of both a single thing is created (*apoteleitai*), when the food takes on an edible character from the seasonings.'[48] The sense of this notion becomes especially palpable in the context of commentary on the *Song of Songs*, not coincidentally at once the most spiced and the most

of New York Press, 1998), 33; *The Zohar*, ed. J. Abelson, trans. M. Simon and H. Sperling (with P. Levertoff, vols. 3 & 4), 5 vols. (London and New York: Socino Press, 1933), III.389. Here citing the latter from the former.

[48] Alexander of Aphrodisias, *On Aristotle's Meteorology 4*, trans. E. Lewis (Ithaca: Cornell University Press, 1996), 89. Clarifies: '*hêdusmata*, which is a metaphor from cooking (sweeteners, condiments, aromatic herbs, spices), are usually taken [by modern commentators] to be non-essential additives to food, while it is precisely these additives which characterize the art of cooking [...] it is the interpreters of the *Poetics* rather than Aristotle who underestimate the importance of condiments to cooking as much as the significance of music for tragedy [...]. The proper use of *hêdusmata* is identified, not only with the art of cooking, but with the civilized way of eating: without seasoning, foodstuffs like meat and fish are undesirable and almost as if they would be eaten raw. This is at least what Hegesandros claims, an author of the second century BC, who 'in his Commentaries (FHG iv 418) says that everybody is fond of *hêdusmata*, not of meats or fish; and if they are not available nobody is happy to offer the meat or the fish (alone), nor does anyone desire the raw and the unseasoned' (G. M. Sifakis, *Aristotle on the Function of Tragic Poetry* [Herakleion: Crete University Press, 2001], 56-70) – a human logic that is followed even (and perhaps especially) when the human is the meal: 'When police searched the kitchen of the late twentieth-century cannibal Jeffrey Dahmer, so the story goes, they found nothing but the refrigerated flesh of his victims and [...] condiments; no fruit, vegetables, cereals or dessert' (T. Morton, *The Poetics of Spice: Romantic Consumerism and the Exotic* [Cambridge: Cambridge University Press, 2000], 31, Morton's ellipsis).

commented-upon of biblical books. Here, elaborating upon more universal links between odour and divine presence, the work of interpreting what spice is becomes spicy itself, the contemplative activity of commentary a becoming-spice. Spice, like a textual aroma of the Paradise which both is and is to come, signifies for the commentator the highest sense of Scripture, the 'anagoge, foretaste of heavenly things.'[49] The possibility for such loving collusion between embodied imagination and intellectual experience, for the interpretation of spice to become a kind of transcendental tautology, is captured in Bernard of Clairvaux's generous exegetical invitation in a sermon on the Song of Songs: 'Every person [...] is free to pursue the thought and experiences, however sublime and exquisite, that are his by special insight, on the meaning of the Bridegroom's ointments.'[50] Alan of Lille, remembering the Song of Songs, defines cinnamon and its theological meaning in one breath: 'Cinnamomum est species aromatica, interna contemplatio' [cinnamon is an aromatic spice, inward contemplation].[51] That *species* here still holds a semantic relation to appearance underscores the overlap. Commentarial contemplation, like those pleasurable sensations that happen to us near other substances, is an *aromatic* phenomenon. This phenomenon is realised in the mind's own becoming-spice or attaining of a quality that is open, expansive, permeating.

As Hugh of St. Victor explains, whereas meditation is an 'assiduous and shrewd drawing back of thought [...] [that] is always about things hidden from our understanding,' contemplation is 'a keen and free observation of the mind expanding everywhere to look into things [...] [and] is about things *as manifest*.'[52]

Spice is not a figure, but a generational integrity of spirit and letter, matter and desire, a sensuous reality whose structure takes the mind that *absorbs* it beyond itself, a hermeneutic psychedelic. Commentary, whose etymology (via *comminisci*, to devise, invent) indicates the creativity of thinking *with* something, is the inverted, external projection or manifestation of spice as such an integrity, the materialization of thinking as a condensation and spreading over a surface; or as Deleuze and Guattari say in their chapter on geophilosophy: 'thinking consists in stretching out a plane of immanence that absorbs the earth (or rather, '*adsorbs*' it).'[53] Susan Ashbrook Harvey perceives this in commenting on Gregory of Nyssa's *Commentary on the Song of Songs*: 'Gregory's olfactory imagery highlights the limits of noetic experience [...] In such instances he seems to rely on what the body can know through smell in order to capture what eludes the mind in understanding.'[54] And Arthur Green feels this when saying 'The canticle itself, we might say, became the "locked garden" of which it speaks, opening itself to those whose hearts longed to dwell by its streams and to be intoxicated by the spices of its perfumed gardens.'[55] Although my body, in the lightness of its earthly gravity, as the very space of odour, of what is neither/both subject and object, needs desperately to delete their critically-safe correlationism (Susan's *seems* and Arthur's *we might say*) or at minimum, ~~strike it through~~. How else will we ever taste the joy Bernard testifies to: 'Happy the mind that has been wise enough to enrich and adorn itself with an assortment of spices such as these'?[56] And not simply to adorn, but to become, following spice as the potentiality of a non-consumerist relation to world: 'In eating the world, boundaries between subject and object are broken down and in another way rigidly maintained. In the poetics of spice, however, a utopian space is imaginable in which boundaries between subject and object evaporate, as they are not predicated on a dialectic of consumer and consumed.'[57] *Where* else will we dine on texts in this way, the way late mediaeval bibliomane Richard de Bury asks us to, like *panthers*: 'You must first eat the volume with Ezekiel, that the stomach of your memory may be internally sweetened; and thus after the manner of the perfumed panther (to the breath of which men, beasts,

and cattle draw near that they may inhale it), the sweet odour of your aromatic conceptions [*conceptorum aromatum odor suavis*] will be externally redolent'?[58]

More discursively, commentary-as-spice embodies the risky work of philosophy, understood by Levinas as the 'adventure' of producing 'the truth of what does not enter into a theme' via the reduction of the said to the saying, a reduction which is 'both an affirmation and a retraction of the said' and which operates as a *continual interruption of essence*: 'The reduction could not be effected simply by parentheses which, on the contrary, are an effect of writing. It is the ethical *interruption of essence* that energizes the reduction.'[59] This is philosophy not, of course, as a discipline among several, but as the spice of disciplines, what makes all disciplines 'ways and kinds of philosophizing,' part of the movement Heidegger calls the attack [*Angriff*] that '*the Da-sein in man launches* [...] *upon man*,' driving us 'out of everydayness and [...] back in to the ground of things.'[60] Like *pilpul*, the movement of philosophical truth-production, says Levinas, is round and multitemporal: 'it is produced out of time or in two times without entering into either of them, as an endless critique, or skepticism, which in a spiralling movement makes possible the boldness of philosophy, destroying the conjunction into which its saying and its said continually enter. The said, contesting the abdication of the saying that everywhere occurs in this said, thus maintains the diachrony in which, holding its breath, the spirit hears the echo of the *otherwise*.'[61] And, it is a movement that originates in proximity: 'Saying states and thematises the said, but signifies to the other, a neighbor, with a signification that has to be distinguished from that borne by words in the said. The signification to the other occurs in proximity.'[62] So commentary, which happens in proximity to and not (as in the case of its bastard offspring the annotated critical edition) in parenthesis from the text, which moves from this proximity as the very ground of its truth, and which is saturated with its own event in the form of the *extra* or outside presence of its essentially deictic gesture, may be called the *savoury circulation of the interruption of our exposure to the otherwise*.[63]

This essentially philosophical othering function of commentary, its diachronic expansion of the saying within the said, or holding open of the event of the text via the very procedure of encircling and enclosing it on all sides, like an unending erection of fortifications each inviting further and new forms of attack, is analogous to the apophatic function of the monstrous as explicated by David Williams: 'In the aesthetic production of the Middle Ages a favoured way of achieving [the progressive negation of logical affirmations about the world and the real] was to deform the representation of the thing described in such a way as to call into question the adequacy of the intellectual concept of the thing in relation to is ontological reality.'[64] Or as Carl Pyrdum writes, saying more than he thinks, 'Nothing *spices* up the margins of your boring old psalter like a picture of a cute monkey doing something really odd, like riding a stork who has a demon's head for a butt.'[65] Just as spice also deforms and distorts the material to which it is applied through a kind of reverse denaturation that turns the merely ingestible into the truly edible, so commentary is a fundamentally monstrous discourse directed toward the denaturing of the text into the earthy, ontic immanence of what it represents. Mazy, decentring, gargantuan, discombobulating, rhizomatic – the formal structure of commentary, geometrically proportional to the characteristic conceptual density and difficulty of philosophical and theoretical language that digressively makes one stop and think, is essential to its quote-unquote-meaning, its desire to multiply explanation and representation fractally, to generate more and more perceptual enclosures, spaces within which the unrepresentable is brought into presence. Commentary thus exemplifies a more universal interventional tendency within human thinking that can be called the *inevitable intrusion of the fictive*, our irreplaceable and individuating poetic compulsion to deform the object of understanding precisely so as to understand it, as the only way it can *actually* be understood.[66]

[66] Cf. 'But since there is some comparison between eating and learning, it may be noted that on account of the fastidiousness of many even that food without which life is impossible must be seasoned' (Augustine, *On Christian Doctrine*, trans. D.W. Roberston, JR. [New York: Macmillan, 1958], 4.11.26).

Yet another way of saying this: commentary *twists* its text spatially, that is, *the geo-metry of commentary is spicy*, following Timothy Morton's ingenious modeling of the word-concept of spice: 'The poetics of spice is a Möbius strip upon which an object appears to behave like a subject, until we have followed this behaviour right round to the "other" side, upon which a subject appears to behave like an object. The distinction, however, between subject and object is not collapsed, and they remain in tension [...]. *Species*, *specious* and *specie* suggest that *spice* belongs to a set of words that denote the non-universal, particular, contingent realm of appearance. But when we look 'behind' spice to find some general or universal category that might substantiate its meaning or fix its place, we find none. We simply re-encounter spice. It is as if the universal were on the side of the particular itself.'[67] Spice is a pure immanence or double one-sidedness whose structure is only intelligible in the form of *spherical* movement, movement that reaches the other side by staying on this one and in so doing simultaneously destroys and realises the distinction between the two. Explorer or exegete, spice is what gets you around earthily, what manifests the universal as the particular itself, in the place where you stand. Via spice, one goes through an impenetrable surface by going over it, by *staying* with it.

So the impulse *not* to escape, *not* to flee, to stay, to remain, not in stillness, but in the movement that one already is, in the more restful motion that dwells in the space of the ontological ambivalence of statements like *I am walking*, that knows it will arrive on the other side only as *this* one, resonates seismically with both geophilosophical immanence and the work of commentary.

---

[67] Morton, *The Poetics of Spice*, 33-5.

The project of Nietzsche's tradition-dislocating and tradition-deepening call to 'remain faithful to the earth' and dwell in the 'new gravity' of the eternal recurrence of the same, a call that emanates with the earth itself, in the moment of Nietzsche's stopping before and being stopped by 'a powerful pyramidal rock nor far from Surlei,' is ordered towards immanence not as the negation or opposite of transcendence, but more truly as its *forgetting*, the experience of which he finds in sound: 'There is no outside! But we forget this with all sounds; how lovely it is that we forget!'[68] Sonically forgetting that there is no outside is not negation, much less some enchanting illusion that there is an outside, but more purely the post-cephalic letting go of the burden of consciousness that there is *no outside*, the apophatic negation of the negation of an outside that opens into full experience of the becoming of the *this*. '[N]o longer bury your head in the sand of heavenly things, but bear it freely instead, an earthly head that creates a meaning for the earth!'[69] Commentary is a homologous *amor fati* that stays with its text gravitationally, remains faithful to it as what remains, as what it cannot depart from. 'The womb of the inexhaustible earth ceaselessly gives birth to what is new; and each one is subject to death [...] Man should not cast aside from him the fear of the earthly; in his fear of death he should – stay. He should stay. He should therefore do nothing other than what he already wants: to stay.'[70] Commentary *stays* with its text, commits wholly to it, both in the quantitative sense of promising to *produce* commentary across its continuity and in the qualitative sense of promising to *extract* significance from each of its moments as a plenitude. In the words of fifteenth-century Talmudic scholar Isaac ben Jacob Campanton, ‘Always strive to show the necessity of all the words of the commentator or author, and for every utterance, why did he say? [...] And you shall take care to compress (*Itsamtsem*) his language and to squeeze out the intention, in order than not one word shall remain superfluous.’[71] In other words, commentary stays with its text *as a sphere*, as an object whose every point, via structural identity with every other, is both infinite and infinitesimal. Commentary’s durational staying with its text equals its self-acceptance as labour, as sustaining and unfinishing diurnal production-towards-death. Commentary thus means praxis, not without, but freeing itself from results, from anxious care about what does not belong to us. Accomplishing nothing, commentary becomes *capable* of everything and so constitutes the potentiality of a hermeneutic whose teleology and instrumentality fundamentally differ from, but do not necessarily contradict, the dominant *thesistic* standards of academic discourse. Commentary is knowledge-production as *immanent* to its labour, whether of writer or reader (which goes to explain the genre’s superior survival in law, religion, philosophy, pedagogy).

---

[68] Quoting, respectively: Nietzsche, *Thus Spoke Zarathustra*, 'Zarathustra's Prologue,' 6; 'The Recurrence of the Same,' notebook entry from August 1881, cited from *Thus Spoke Zarathustra*, trans. G. Parkes (Oxford: Oxford University Press, 2005), xxii; and *Thus Spoke Zarathustra*, 'The Convalescent,' 175.

[69] Nietzsche, *Thus Spoke Zarathustra*, 'On the Hinterworldy,' 21.

[70] F. Rosenzweig, *The Star of Redemption*, trans. B. E. Galli (Madison: University of Wisconsin Press, 2005), 9-10.

Why not therefore also make in *this* place a hermeneutic bridge between commentary and the sound which Nietzsche indicates as the vehicle of immanence, of what cannot, if it is to really be itself, have a vehicle? Again, spice provides the link, the material to build across space.

---

[71] Cited from Boyarin, ‘Pilpul: The Logic of Commentary,’ 6.

'The verb (*verbum*),' says Isidore of Seville, is so called because it resounds by means of reverberation (*verberatus*) in the air.' And: 'Spices [...] seem to have gotten the name "spice" (*aroma*) either because they are proper for putting on altars (*ara*) for invocations to the gods or because they are known to blend and mingle themselves with air (*air*). Indeed what is scent if not air that has been tinctured with something?'[72] Ergo, the spiciness of commentary similarly consists in its being textual sound, semantic aroma, the re-verberation, to play Isidore's etymology backwards, of the word it comments on.

Like word, like spice, commentary is space-filling. Whence Gumbrecht's suggestion of an imminent return to commentary in the context of our being haunted by new technic vistas of emptiness: 'The vision of the empty chip constitutes a threat, a veritable *horror vacui* not only for the electronic media industry but also, I suppose, for our intellectual and cultural self-appreciation. It might promote, once again, a reappreciation of the principle and substance of *copia*. And it might bring about a situation in which we will no longer be embarrassed to admit that filling up margins is what commentaries mostly do – and what they do best.'[73] Yet commentary does not simply fill space the way all writing *takes up* space. Rather, it fills space only in the sense that it also *folds* space, produces moments of identity across it, across the impassible, intimate distance that commentary auto-institutes as the text/commentary distinction. This distinction is simultaneously the inviolable, irreducible space of writing itself (the dimension of the page that cannot be filled in order for writing to ex-sist) and the crease through which commentary folds this space. Accordingly, commentary works to hold forever open *and* totally fill writing's space, as if to absolutely disclose the place of writing, which means to realise it as *curved space*, the immanent space-becoming-place through which everything leads back to itself. This spatial curving that commentary realises is visible materially as the becoming-round of the text/commentary border and conceptually as the turning motion commentarial reading and writing take: away from the text, turning back towards it, repeat [...] Commentary rotationally transforms the *space* of writing into an earthly *place*. Simple textual space-filling discloses the space of writing as writing's potentiality, the page, by enclosing and surrounding it *from the inside*. Commentary, whose meaning is founded upon proximate separation from its text, continues the enclosure *from within the outside* and thus holds open the space of writing by bounding it, pushes writing to the limit where the space of writing *intersects* with what it already is, the real space of the world. In other words, commentary does not merely take up room, but *uses room* to make itself the world, to bring its text back to earth. Infinite commentary on an infinitesimal text is commentary's ideal, not actually, but only as an unimaginable concept reasserting its deep desire, namely, to spatially achieve the ontological breaking-point of the text, the situation where there is *neither anything outside the text nor nothing outside the text*. Commentary seeks not to end, but to un-end writing, to arrive at writing's plenitude and ouroboric starting/stopping point, the saturated phenomenon of its perfection, as grasped by Agamben while contemplating the completion of the unfinished last work of Damascius, and final scholarch of the School of Athens and so-called last of the Neoplatonists,

---

[72] Isidore of Seville, *Etmologies*, trans. Stephen A Barney (Cambridge: Cambridge University Press, 2006), 1.9.1, 17.8.1, respectively.

[73] Gumbrecht, *The Powers of Philology*, 53.

On First Principles (!): 'The uttermost limit thought can reach is not a being, not a place or thing, no matter how free of any quality, but rather, its own absolute potentiality, the pure potentiality of representation itself: the writing tablet! [...] This was why he was unable to carry his work through to completion: what could not cease from writing itself was the image of what never ceased from not writing itself [...] [E]verything was finally clear: now he could break the tablet, stop writing. Or rather, now he could truly begin.'[74] This point is not being finished with writing, but writing's becoming an unending beginning, the sphericization of the space of writing or our finding of the page as *unbounded finitude*, a surface for limitless writing whose every mark is first and last. Commentary's filling of the margins is an exercise in intentional, exuberant futility directed toward an ultimate forgetting of the outside, toward continual writing of the omnipresent impossibility of separateness, the always-never asymptotic union of text and world.

All of above goes to explain why, in the appendix of Frank Herbert's *Dune*, we read that 'the O.C. [Orange Catholic] Bible and the Commentaries,' a product of humanity's encounter with the outer dark via space travel and the textual analogue of the orange spice gas used by Guild Navigators to fold space, 'permeated the religious universe.'[75]

Introduction to Schelling's *On the World Soul*

Iain Hamilton Grant

EDITIONS

The first edition (1798) of Friedrich Wilhelm Joseph Schelling's *On the World Soul. An Hypothesis of Higher Physics for Explaining Universal Organism* was published by Perthes in Hamburg, as was the second, revised edition (1809) to which a new Foreword and Essay 'On the Relation between the Real and the Ideal in Nature, or the Development of the Basic Propositions of the Philosophy of Nature from the Principles of Gravity and Light' were added. The third edition (1809), also published by Perthes, slightly revised the second edition, but added no new material.

The edition from which the present translation is taken is that found in vol. II of K.F.A. Schelling's edition of *Schellings sämmtliche Werke* (*SW*), XIV vols (Stuttgart and Augsburg: J.G. Cotta'scher Verlag, 1856-61), reprinted in a new order, ed. Manfred Schröter (Munch: Beck, 1927), and the numbers in the margin refer to this edition. It is based on the 1809 edition of Schelling's text, and supplies the changes from the first edition in footnotes.

The text is found in vol. I, 6 of the new *Historisch-Kritische Ausgabe* (*HKA*) of Schelling's works, which provides a concordance with *SW*, but does not contain the 1806 essay, despite retaining the second edition's Foreword, which serves principally to introduce the accompanying essay, along with Schelling's revisions to the main text (in footnotes). The *HKA* edition is a work of considerable scholarship, with some one hundred and fifty pages of explanatory notes (some translated here), and was used as the source for Stéphane Schmitt's translation *De l'âme du monde* (Paris: Éditions Rue d'Ulm, 2007), which I have also consulted. Also consulted is the magnificent *HKA Ergänzungsband zu Werke Band 5 bis 9*, which contains a wealth of material on the scientific background against which Schelling produced his naturephilosophical writings up to 1800. Since the *HKA* remains incomplete yet infuriatingly references Schelling's works, where these have appeared in the *HKA*, only in that edition's pagination, I have maintained the *SW* pagination, since it remains the only complete referenceable edition of Schelling's works as a whole.

The section translated here includes the first edition preface (*SW* II, 347-51), which contains the nearest thing to an overview provided for this work, and the initial setting out of the 'primary force in nature' (*SW* II, 381-97). The footnotes are in part my own, in part K.F.A. Schelling's notes to *SW* II, and in part Jörg Jantzen and Thomas Kisser's, from *HKA* I,6, and their provenance is noted in the text.

INTRODUCTION

This is the second of Schelling's three major, early naturephilosophical books, published in 1798 between the *Ideas for a Philosophy of Nature* (1797; *SW* II, 1-343) and the *First Outline of a System of Naturephilosophy* (1799; *SW* III, 1-268). The other key naturephilosophical works of this period are the *Introduction to the Outline* (1799; *SW* III, 269-326) the *Universal Deduction of the Dynamic Process* (*SW* IV, 1-78), which Schelling published in his *Journal of Speculative Physics* vol. 1, no. 2 (1800). Across these works, Schelling had demonstrated an extraordinary capacity for synthesising the results, procedures and hypotheses that were leading the field in each of the sciences. As a result, the *Weltseele* is a systematic yet experimental, or 'constructive' work in the sense Schelling gave this term, pursuing the 'decomposition' of the All by chemical, electrical, meteorological and vital means across the entirety of the 240 pages of the *SW* it takes up.

It is often claimed that Schelling merely pursues the goals established by Kant's transcendental philosophy – namely, to suspend ontology in the interests of rational certitude, and therefore to place the ethical at the head of philosophy. Yet whereas analysis and synthesis were powers of the understanding for Kant, for Schelling, they are powers of nature; not content with chemical *analogies*, Schelling pursues a chemical philosophy, a distinction recognised by Novalis when he called Schelling 'the philosopher of the new chemistry, the absolute oxygenist'.[1]

Accordingly, *On the World Soul* presents a single, consistent 'decomposition' or *analysis* of nature into its primitive forces. Indeed, 'primitive force' is precisely the

---

[1] Novalis, *Die Christenheit oder Europa und andere philosophische Schriften* (Köln: Könnemann, 1996), 300.

object of a 'higher science of nature', i.e., that at which this science aims. The work therefore pursues this object through the media of light, heat, gases, electricity, magnetism, meteorology, until it arrives at a determination of the concept of polarity, which became something of the cliché of Idealist philosophy of nature. At the core of this concept, however, is the 'dualism' or *real opposition* of forces[2] that animate all natural phenomena. Therefore, upon making the transition from 'anorgic' to organic nature, *On the World Soul* demonstrates a continuity of analysis in the twofold sense that primitive forces are thereby exhibited as the common medium of all phenomena, and that there is therefore no *specifically vital matter or vital force.* Rather than seek a substance dualism dividing the natural world, Schelling pursues that immanent duel of forces throughout it, by which nature is *organised.* So just as the concept of polarity is misunderstood if considered purely conceptual rather than actual, so too the oft-touted 'organicism' of romantic naturephilosophy ignores the true focus of Schelling's work: the origins and conditions of natural *organisation*, of which minerals, animals, weather systems and chemicals are merely regional expressions.[3]

---

[2] See the third thesis with which the present translation concludes: 'real antithesis is possible only between things of one kind and common origin' (SW II, 397). Note the *chosiste* difference Schelling here introduces with respect to Kant's account of real antithesis in 'Attempt to introduce the concept of negative magnitudes into philosophy' (Ak. II, 167-204), tr. David Walford in *The Cambridge Edition of the Works of Immanuel Kant. Theoretical Philosophy 1755-1770* (Cambridge: Cambridge University Press, 1992), 207-41.

[3] There has been a lively debate on Schelling and self-organisation, beginning with Marie-Luise Heuser-Kessler, *Die Produktivität der Natur. Schellings Naturphilosophie und das neue Paradigma der Selbstorganisation der Naturwissenschaften* (Berlin: Duncker und Humbolt, 1986). Bernd-Olaf Küppers' *Natur als Organismus. Schellings frühe Naturphilosophie und ihre Bedeutung für die moderne Biologie* (Frankfurt: Klostermann, 1992) is a critical response to the thesis that there is a parallel between the modern natural scientific conception of self-organisation and Schelling's conception of the

What Schelling may here be said to retain from Kant is therefore twofold: (1) the conclusions of the latter's study of real (or actual, *wirkliche*) opposition; (2) that because the primitive conflict of forces is the *object* of the philosophy of nature, such forces are never (by 1, above) 'transcendently' available, i.e., uninvolved in actual oppositions, on the one hand, or something 'in themselves', on the other. In other words, the analysis of forces results necessarily in actual individuation. Rather therefore than the structure of consciousness furnishing phenomena and their conceptual forms, nature is its own analyst. This point is clearly made by Karl August Eschenmayer,[4] whose *Propositions from the Metaphysics of Nature* Schelling excitedly noted towards the end of his *Ideas for a Philosophy of Nature* of the same year.

---

same, and the debate is critically presented by Camilla Warnke, 'Schellings Idee und Theorie des Organismus und der Paradigmawechsel der Biologie um die Wende zum 19. Jahrhundert', *Jahrbuch für Geschichte und Theorie der Biologie* 5 (1998): 187-234. See also *Selbstorganisation. Jahrbuch für Komplexität in den Natur-, Sozial- und Geisteswissenschaften 5: Schelling und die Selbstorganisation* (1994), ed. Marie-Luise Heuser-Kessler and Wilhelm G. Jacobs.

[4] Karl August Eschenmayer (1768-1852), medical doctor (1797) and chief medical officer (1800-1811) in Kirchheim an der Teck, Württemberg, before becoming professor of medicine and philosophy in the University of Tübingen. After two excellent critiques of Schelling's philosophy of nature, the first, 'Spontaneität = Weltseele', published in Schelling's own *Journal of Speculative Physics* vol. 2, issue 1 (1801), and the second, anonymously, as 'Über Schelling: Erster Entwurf und Einleitung' in the *Erlanger Literaturzeitung* no.67 for July 4, 1801. In *Propositions from the Metaphysics of Nature applied to Chemical and Medical Objects* (*Sätze aus der Natur-Metaphysik auf chemische und medizische Gegenstände angewandt.* Tübingen: Jacob Friedrich Heerbrandt, 1797: 8), from which Schelling quotes at the end of the *Ideas for a Philosophy of Nature* (*SW* II, 313-14n; tr. Errol E. Harris and Peter Heath. Cambridge: Cambridge University Press, 1988: 249), Eschenmayer writes: 'There is no absolute freedom or bondage of the forces in matter. – For the concept of matter would be eliminated thereby. In absolute freedom the forces would be independent of one another, and an infinitely larger or smaller degree of matter, that is, no degree at all, would be existent. Absolutely bound, the gradation would be equally eliminated and sensibility = 0.' Jörg Jantzen gives an excellent account of Eschenmayer's work in Thomas Bach and Olaf Breidbach, eds., *Naturphilosophie nach Schelling* (Stuttgart-Bad Canstatt: Frommann-Holzboog, 2005), 153-79.

In deciding whether naturephilosophy extends Kant's transcendental philosophy or inverts it, such passages are crucial:

> [I]t is only from the standpoint adopted by the metaphysician of nature that the necessary assumption of these forces can be proven and the duplicity of matters and forces which so many have introduced into natural science to explain the phenomena, justified. The theoretical dualism for natural science is actually postulated by dynamics, but we do not commonly observe its lineage. Thus we set acids and alkalis in opposition to one another, two electrical and two magnetic materials; hence Gren assumes a gravitational and an expansive force [...]. Ultimately such a dualism is deduced from the necessity of the original positing and oppositing, which are the conditions under which even the possibility of our consciousness stands.[5]

If the dualism in question amounts to the actual opposition of forces – in a later passage from the same work,[6] Eschenmayer argues that even Kant *proves their existence*, rather than demonstrates their transcendental necessity – and conditions 'even the possibility of our consciousness', it is clear that the 'positing' at issue is primitive, issuing *in* rather than *from* consciousness. It is precisely this inversion that *On the World Soul* pursues. Of course, that the ensuing 'constructions' thereby lose any purely epistemic guarantee follows from this; and here we note, albeit telegraphically, a central difference between Schellingian and Hegelian speculation: if the latter aims at the identity of identity and difference, the former differentiates the identity of the dualism that forms it.

---

[5] Eschenmayer, *Propositions from the Metaphysics of Nature*, 3.

[6] Ibid, 60.

Finally, then, what sort of a theory of nature is the higher one from which this hypothesis concerning 'universal organism' derives? It shares with Kant's *Transition between Metaphysics and Physics* (*Opus Postumum*),[7] and with a great many contemporaneous natural scientists, the aether hypothesis. While the beginning of the twentieth century marked the end of the hypothesis concerning such a substance, its real import is that it is an attempt at a physical field theory. As such, the problem it poses concerns whether this 'universal medium' is a substance separable from the forces it vehiculates, or whether it is nothing other than the totality of such forces in actual oppositions. If this seems a merely historical point now, consider the extent to which powers ontologists from Bruno to our contemporaries, consider forces not as primitive, but as properties – the question 'what of?' still remains.[8]

In consequence, the animating 'soul of the world' that is the object of the work translated below is no indicator of a substance dualism, and instead assumes the character of a properly dynamic, field-theoretical theory of nature *within which alone* a dualism not of substances, but of forces accounts for individuation and organisation.

---

[7] Schelling supplies this as the title of what is published as the *Opus Postumum* in his obituary for Kant (SW VI, 8).

On the World-Soul

F.W.J. Schelling

Foreword to the First Edition 34

The reader, provided only that he has sufficient desire or curiosity, will become acquainted with what the goal of this treatise might be, and why it bears this inscription at its head.

The author first finds it necessary to explain himself on two points, so that no prejudices are assumed with regard to this inquiry.

The first is that no artificial unity of principles is sought or intended in this work. Consideration of the universal metamorphoses of nature as well as the state and progress of the organic world certainly conducts the natural scientist to a *common principle* in which, fluctuating between inorganic and organic nature, is contained the first cause of all change in the former and the final ground of all activity in the latter. Because this principle is *everywhere* present, it is *nowhere*; and because it is *everything*, it cannot be anything *determinate* or *particular*; language has no appropriate term for it, and the earliest philosophies (to which, after having completed its cycle, ours is gradually returning) have handed down to us an idea of it only in a figurative guise.

But a unity of principles is unsatisfactory if it does not return to itself through an infinite series of individual
48 effects. I hate nothing more that the mindless striving to eliminate the multiplicity of natural causes through fictitious identities. I observe that nature is satisfied only by the greatest dominion of forms, and (according to the claim of a great poet)[1] that it delights in *arbitrariness* in the deathly management of decomposition. The law of gravitation alone, to which even the most mysterious of cosmic phenomena are finally reduced, does not only permit, but even causes the heavenly bodies to be disturbed in their course, so that in the most perfect of cosmic orders there reigns the greatest possible disorder. Thus has nature circumscribed the vastness of space, which it has sealed within eternal and unchanging laws, widely enough in order within it to delight the human mind with the appearance of lawlessness.

Just as soon as our consideration of the idea of nature as a *whole* arises, the antithesis between mechanism and organism, which has held up the advance of natural science for long enough, and that may be as contrary to our inquiry as to many others, disappears.

It is an old illusion that organisation and life cannot be explained from natural principles. – If it were thus to be said: the *first* origins of organic nature are *physically* inscrutable, then this *unproven* assertion serves only to discourage investigators. It is of course permissible to oppose one audacious assertion to another equally audacious one, and so science advances not a single step. Yet at least *one* step towards this explanation would be taken were we able to show that the graduated series of every organic being is formed from a gradual evolution of one and the same organisation.

---

[1] Schelling is referring to Schiller's *Dom Karlos*, act 3, from which he borrows his language.

That our experience has known no reorganization of nature, no transition of one form or type into the other (although the metamorphoses of many insects and, if every bud is a new individual, also the metamorphoses of plants could at least be adduced as analogical phenomena) is no proof against this possibility; for, were a defendant to answer it, the changes to which organic as much as 34 anorgic [*anorgische*] nature is subjected, could (until a universal stagnation of the organic world comes about), have happened over ever longer periods, for which our small periods (which are determined by the cycles of the earth round the sun) provide no measure, and are so large that until now there has been no experience of the course of a single one. Fine. Let us abandon these possibilities and see what then is true and what is false in the antithesis between mechanism and organism, so as to determine with as much certainty as possible the limits within which our understanding of nature must remain.

What then is that mechanism which frightens you as would a ghost? Is mechanism something that persists in itself, or is it not instead simply the negative of the organic? Must not the organic precede the mechanical, the positive precede the negative? Now if in general the negative presupposes the positive (as darkness does light, as cold does heat) and not vice-versa, then our philosophy must not begin with mechanism (as the negative), but rather with the organic (as the positive), and therefore of course the former is not so much to be explained by the latter, but rather only can be explained by it. Not where there is no mechanism, no organism, but rather conversely, where there is no organism, there is no mechanism.

To me, organisation in general is nothing other than an arrested stream of causes and effects. Only where nature has not inhibited this stream, does it fly forward (in a straight line). Where it inhibits it, it turns back on itself (in a circular line). Therefore, the concept of organism does not rule out all succession of causes and effects; rather, this concept indicates only a succession that *enclosed within certain limits*, flows back on itself.

Now, that the original limit of mechanism cannot be explained empirically, but must instead be *postulated*, I myself will show (by induction) in what follows; it remains
50 however to be proven philosophically. For since the world is only infinite in its finitude, and an unrestricted mechanism would destroy itself, then universal mechanism must be restricted *to infinity*, and there will be as many *individual, particular worlds* as there are spheres within which universal mechanism revolves in itself, so that, in the end, the *world* is an *organisation*, and a *universal organism* is itself the *condition* (and to that extent, the positive) of *mechanism*.

Viewed from this height, the particular successions of causes and effects (that delude us with the appearance of mechanism) disappear as infinitely small straight lines in the universal curvature of the organism in which the world itself persists.

Now what philosophy has long taught me, that the positive principles of organism and mechanism are the same, I have sought to prove in the following work from experience, in that the universal changes in nature (on which even the existence of the organic world depends), lead us at last to the same *first hypothesis* on which the universal assumption of natural scientists has long since made the explanation of organic nature dependent.

The following treatise therefore falls into two sections, the first of which treats of the force of nature that is manifest in the universal changes, while the other undertakes to search for the positive principle of organisation and life. The common result of these is that *one and the same principle binds anorgic and organic nature.*

The incompleteness of our knowledge of first causes (such as electricity), the atomistic concepts that lay here and there in my way (e.g. in the theory of heat), and finally the impoverishment of the dominant modes of thought regarding many objects of physics (e.g. meteorological phenomena), soon required that I be early led in the first section to make many special explanations – explanations that scatter the light, that I would wish to cast on the whole amongst particular objects, so indeed, that at the end they 35
can be collected again in a common focus.

The *wider* the sphere of inquiry is drawn, the more clearly one sees the deficiency and impoverishment of the experiments that up to now fall within its circumference, and thus few will feel the incompleteness of this attempt more deeply or vividly than he who conducts it.

⁂

Note. This work is not to be viewed as a continuation of my *Ideas for a Philosophy of Nature.* I will not continue it before I find myself in a position to conclude the whole with a *scientific physiology*, that alone can round off the whole. First I hold it as a duty not merely to *venture* something in this science, the errors of which at least the perspicacity of others will effect the discovery and refutation.

I must nevertheless wish that the reader and critic of this treatise be familiar with the ideas presented in that work. The authority for assuming all positive natural principles as homogeneous, is only to be gained philosophically. Without this *postulate* (I presuppose that one knows what a *postulate with a view to a possible construction* is),[2] it is impossible to construct the first concepts of physics, for example, the theory of heat. Idealism, which philosophy is gradually introducing into all the sciences (it has long since become dominant in mathematics, especially since Leibniz and Newton), still seems to be little understood. The concept of *action at a distance*, for example, against which some still beat their heads, rests entirely on the idealist notion of space: for according to this notion, two bodies at the greatest possible distance from each other can be represented as in contact with one another, and contrariwise, bodies which (in accordance with the common conception) are in actual contact, as acting on one another at a distance. It is quite true that a body only *acts* where it *is*, but it is equally true that it only *is* where it *acts*, and with this single proposition the last piece of armour of the atomistic philosophy is overcome. I must abstain here from offering still further examples.

---

[2] Schelling's theory of the postulate is given in 'On Postulates in Philosophy', the appendix to the 'Explanatory Essays on the Science of Knowledge' (1797), where Schelling writes, 'the expression "postulate" is borrowed from mathematics. In geometry, the *original* construction is not *demonstrated*, but *postulated*. This *original* (the simplest) *construction* in space is *the moving point*, or the *line*' (*SW* I, 444). Adopting this as the principle of a constructive philosophy, Schelling advocates a philosophy concerned 'only with original constructions', which does not 'consider any existential proposition *analytically*, but *synthetically* (as *arising* in synthesis)' (*SW* I, 447).

PART I: ON THE FIRST FORCE OF NATURE 37

> Venient tempus, quo ista, quae nunc latent, in lucem dies extrahat et longioris aevi diligentia. Ad inquisitionem tantorum una aetas non sufficit. – Itaque per successiones ista longas explicabuntur. Vienet tempus, quo posteri tam aperta nos nesciisse mirentur.
>
> [*Grant him time and lifelong diligence to bring to light what is hidden. Life is not sufficient for so many inquiries together. – Therefore let him make far-reaching advances in explanation. In time to come, we must wonder to whom so much will later be clear.*]
>
> Seneca[3]

Every motion that returns to itself presupposes, as the 38 condition of its possibility, a *positive* force that (as *impulse*) *initiates* motion (turning the starting point, as it were, into a line), and a *negative* force, that (as attraction), draws the movement back into itself (or prevents it from flattening out into a straight line).

In nature everything strives continuously forwards; we must seek the ground as to why this is so in a principle that, as an inexhaustible source of the *positive* force, always reinitiates movement in the world and uninterruptedly maintains it. This *positive* principle is the *first force of nature.*

But an invisible power draws all the world's phenomena into an endless circuit. We must seek the ultimate ground as to why this is so in a *negative* force that, in that it continuously limits the effects of the positive principle, conducts motion in general back to its source. This *negative* principle is the *second* force of nature.

---

[3] Seneca, *Naturalis Quaestiones*, VII, 25, 4-5.

These two conflicting forces conceived at the same time in conflict and unity, lead to the idea of an *organizing principle*, forming the world into a system. Perhaps the ancients wished to intimate this with the *world-soul*.

If the originally positive force were infinite, it would lie entirely beyond the limits of all *possible perception*. Restricted by the opposing force, it becomes a *finite magnitude* – it begins to be an object of perception, or manifests itself in *phenomena*.

The one *immediate* object of *intuition* is the *positive* in every phenomenon. We can only *infer* the *negative* (as the cause of the merely *experienced*).

82 The *immediate object* of the *higher theory of nature* is therefore only the *positive* principle of all motion, or the *first force of nature*.

The first force of nature *conceals* itself behind the *individual phenomena* in which it is revealed to the desirous eye. In *individuated matter* it breaks out throughout the entire cosmos.

To grasp this *Proteus of nature* that recurs again and again in ever changing forms and in numberless phenomena, we must cast the net more widely. Our progress will be slow, but all the more certain.

The matter that in every system radiates from the centre to the periphery – *light* – moves with such force and velocity that some have even doubted its materiality, since it lacks the universal characteristic of matter, inertia. But to all appearances, we know light only in its *propagation*; most probably it is only in this state of *original motion* capable of reaching our eyes as light. Now every *propagation* and every *becoming* is accompanied by a particular and appropriate motion, however. If a very much higher yet nonetheless finite degree of elasticity were instantaneously to arise, there will also arise a matter of the highest degree of elasticity that, since the essence of elasticity is the expansive force, will expand into a space in proportion to the degree of this force. This will now give the appearance of matter in free motion, as if, so to speak, exempted from the universal laws of inertia, it held in itself the cause of its own movement.

Now this movement, however great or fast we may assume it to be, differentiates itself from every other, so that an equilibrium of the forces arises in any given matter, only according to degree. For let that elastic matter, without 38
any resistance that a body of lesser elasticity could set against it by its impenetrability or by the attractive force of its dissemination, spread out in a completely empty space, then since the degree of its elasticity is of course finite, and the elasticity of every matter decreases in proportion as the space in which it expands is increased, by which its gradually lowering elasticity reaches an equilibrium of forces relative to its degree of expansion, and thus makes *rest,* that is, a permanent state of matter, possible.

Therefore *light*, although it moves with wonderful speed, is nevertheless for that very reason neither more nor less *inert* than any other matter whose movement is no object of perception. For, to state it at the outset, *absolute* rest in the world is *not anything*, all rest in the world is merely apparent, and properly only a *minus*, but in no way a complete absence, of motion (= 0). The movement of light is therefore an *original* movement of which *every* matter as *such* has its share, except that, no sooner has matter *reached* a permanent state, with the minimum speed that light would equally have attained, than its original forces will have reached a common moment.

Since every matter fills its particular space only through the reciprocity of opposing forces, that it therefore *permanently* fills *that same* space, i.e. that the body persists in its condition, cannot be explained without accepting that these forces are equally *active*, whereby then the non-thing of absolute rest disappears of itself.

All rest and all persistence of a body is simply *relative*. The body *rests* in relation to a *determinate state* of matter; as long as this state continues (as long, e.g., as the body is solid or fluid), the moving forces will fill space with *equal quantity*, i.e. they will fill *the same* space, and *to that extent* the
84 body will appear to *rest*, although that this space is continuously filled can only be explained by a continuous motion.

That therefore light expands on all sides in rays, must be explicated by conceiving it as in *constant propagation* and as *originally* expansive. That light also reaches relative rest we can directly infer from this, that the motion of light from an unending mass of stars is not transmitted to us.

It is not in the interest of natural science to admit anything *unlimited*, nor any absolute force, but rather to consider each of these always and only as the *negative of its opposite*. Now we too may, of whichever of the forces we wish, let it grow to the highest degree thinkable, but we will never be able to bring it to the *absolute* negation of its opposite. Hence the striving of those who derive universal gravitation from the impact of some unknown matter that forces bodies against one another, is entirely idle; for since this matter creates gravity, without itself being heavy, we must conceive it as an absolute negation of the attractive force; but as such it would cease to be an object of possible construction and would as it were disappear into the universal repulsive force, leaving no material principle to explain universal gravitation, but only the obscure idea of a *force*, which is precisely what this hypothesis sought to avoid.

What keeps light within material limits, what *finally* turns its motion into an object of perception, is the force of attraction.[4] If some natural scientist assumes light itself or a part thereof as *imponderable*, all they thereby state is that a great force of expansion (which, as an original force, leaves all our explanations at a standstill) is active. Since however 38
this force of expansion never exceeds the limits of matter, i.e. can never become absolute, so *gravity* can certainly be considered as *collapsing* into a matter, as into light, but never as completely *negated*.

To that extent, it is not absurd to assert a *negative gravity* of light;[5] for since this expression, borrowed from mathematics, always indicates not a mere *negation*, but rather an *actual opposition*,[6] so *negative attraction* is in fact nothing more nor less than *real repulsion*,[7] so that this term states nothing more than what we have long known, that a repulsive force is active in light. Should this however suggest some cause by which the absolute (not the specific)[8] gravity of the body may be reduced, the concept of such a cause has long since been banished into the realm of fantasy.

---

[4] 1st ed.: 'its ponderability'. [K.F.A. Schelling].

[5] The concept of 'negative gravity' was applied by Friedrich Albert Carl Gren, amongst others, although he later modified it, in his *Systematic Handbook of General Chemistry*, 4 vols (2nd edition, Berlin and Halle: Waisenhaus 1794-6), vol.1, 136: 'The gravitational being of particles of free caloric cannot consist in their rectilinear radiation. Hence it may already be demonstrated *a priori* that caloric is not subject to gravity, and nor can it be proven to be gravitational by any number of *a posteriori* experiments. Caloric is therefore an imponderable elastic fluid.' [editors' note, *HKA* I,6: 288].

[6] See Kant, 'Attempt to introduce the concept of negative magnitudes into philosophy', *Kants Werke* (Berlin: Königliche preussische Akademie der Wissenschaften, 1901ff) *Ak.*.II, 165-204, tr. David Walford and Ralf Meerbote in *Theoretical Philosophy 1755-1770* (Cambridge: Cambridge University Press, 1992, 202-41; here *Ak.* II, 193; 1992: 230-31: 'So far I have merely considered the grounds of real opposition, in so far as they *actually* posit in one and the same thing determinations, of which one is the opposite of the other. A case in point would be the motive forces of one and the same body which tend in exactly the opposite direction; and here the grounds cancel their reciprocal consequences, namely the motions. For this reason, I shall [...] call this opposition *actual opposition* (*oppositio actualis*).'

If accordingly no degree of elasticity can be thought as the highest possible, so that above this there are still higher degrees, and between these given degrees and the complete negation of all degree innumerable intermediary degrees can be thought, so too can each elastic material can be considered as the mean proportion of a higher and a lower degree, that is, as *composite*. If *we* have the means to decompose such a matter chemically, we never arrive at it; it is enough that such a decomposition is possible, and that nature has the means to effect it. Therefore (even if the colours of a body do not indicate a decomposition of light), we will consider *light* not as a simple element, but rather as the product of two matters,[9] one of which, as elastic as light, can be called the *positive* matter of light (the *fluidum deferens* according to de Luc), and the other, less elastic by nature, the *negative* (ponderable) matter of light.

---

[7] Kant *Ak.* II, 179-80; 1992: 218: 'Now if you call *attraction* a cause, of any kind you please, in virtue of which one body constrains other bodies to press upon the space which it itself occupies or to set in motion (though here it is sufficient simply to think of this attraction), then impenetrability is a *negative attraction*. This serves to show that impenetrability is as much a positive ground as any other motive force in nature. And since negative attraction is really true repulsion, it follows that the forces with which the elements are invested and in virtue of which these latter occupy a space, albeit in such a way that they impose limitations even on space itself by means of the conflict of the two forces which are opposed to each other – it follows, I say, that these forces will give rise to the elucidation of many phenomena.'

[8] 'With the term "specific gravity" is designated the relations of the weight of a body to the space it occupies. A body is called *specifically more gravitational* or *heavier*, than another when it weighs more, *specifically lighter* when it weighs *less* than the other, when they occupy the same space.' J. S. T. Gehler, *Physikalisches Wörterbuch*, 6 parts (Leipzig: Schwickert, 1787-1796), part 3, 902 [editors' note *HKA* I,6: 291].

[9] 1st ed.: '*two matters*' [K.F.A. Schelling].

The positive matter of light is, in relation to light, the ultimate ground of its susceptibility to expansion and *to that extent*, absolutely elastic, although we cannot at all think it 38 as matter without considering even *its* elasticity in turn as finite, that is, as itself *composite*. It is the first principle of natural science that no principle be considered absolute, and that a *material* principle be assumed as a vehicle of every force in nature. Natural science has, as if by some happy instinct, steadfastly pursued this maxim, and would sooner always hypothesise unknown matters to explain natural phenomena than resort to absolute forces.

Hence the advantage of the concept of the *original forces*, which dynamic philosophy has introduced into natural science,[10] is now strikingly evident. Namely, they do not in any way serve as *explanations*, but rather only as *limit concepts* for empirical natural science, by means of which the freedom of the latter is not only unthreatened, but is rather secured, because the concept of forces, since each of these admits an infinity of possible degrees, none of which is an absolute (the absolutely highest, or the absolutely lowest), opens for it an infinite scope within which it can explain all phenomena *empirically*, that is, from the *reciprocity of diverse matters*.

---

[10] The background of the 'dynamic philosophy' to which Schelling here refers is provided by Kant's *Metaphysical Foundations of Natural Science*, but also by his own *Ideas for a Philosophy of Nature*, which draws also on Eschenmayer's *Propositions from the Metaphysics of Nature* (cf. n.4 in my introduction above, and George di Giovanni, 'Kant's Metaphysics of Nature and Schelling's *Ideas for a Philosophy of Nature*, *Journal of the History of Philosophy* vol.17 (1979): 197-295.

Indeed, natural science has from the very first helped itself to this freedom in explanation, albeit indeed without being able to protect itself against the charge of arbitrariness which from this point on becomes invalid, since according to the principles of a dynamic philosophy outside the sphere of known matters there yet remains a broader one for unknown, other matters that yet we cannot pass off as invented, as soon as the degree of their energy is assumed to be proportional to actually observed phenomena.

So much for the rectification of common notions.

When I assert the *materiality* of light, I do not thereby exclude the opposite view, namely, that light is the motion of a moved medium. In the *Ideas for a Philosophy of Nature*, I posed the question: Must not the light from the sun propagate to us by decomposition? At issue was whether
87 we might not unify the *Newtonian* and *Eulerian* theory of light. What exactly do Newton's supporters want? A matter that has its own, proper relations to bodies, that is, that is capable of its own effects.[11] And what, by contrast, does Euler, and those who agree with him, want? That light is the mere phenomenon of a moving, vibrating medium. Yet must the vibration be necessarily *mechanical*, as Euler thinks? Who can prove that, between earth and sun, a matter does not fill it that is decomposed by the effect of the sun; and could not this decomposition propagate even into our atmosphere, since in precisely this there is a source of light?

---

[11] '*Aether, celestial air, the fine matter of the universe, materia subtilis, elementum primum Cartesii.* Names that the natural scientist applies to the finest and most elastic fluid matter that is spread throughout the entire universe and penetrates the interstices of all bodies. Everything that can be said about these objects is *hypothetical* and acknowledged only to explain certain appearances; direct and clear experimentation on the existence and properties of the aether are entirely lacking.' Gehler, *op. cit.*, part 1: 82 [editors' note *HKA* I,6: 294-5].

In this way, we would have what Newton wants: a particular light-matter that is equally capable of chemical relations; and what Euler wants: a propagation of light by simple vibration of a decomposable medium.

As far as I know, both *Newton's* and *Euler's* supporters admit that each of these theories have their own difficulties, which elude those of the opposing theory. Would it not therefore be better, instead of setting these views in opposition one to the other as has until now been done, to consider them as *reciprocally supplementing one other*, so as to combine the advantages of both into *one* hypothesis?

One important argument for this new theory is that all the light we know is indeed only the *phenomenon of a propagation.* For

1) Assuming too, that the light that now reaches us is the same light that less that around eight minutes before radiated from the sun, then as has already been shown, we cannot explain the diffusion of light in all directions without assuming that this motion is *original.* But there is original motion in a matter only for so long as it has not yet reached a *dynamic equilibrium*, that is, for as long as it is still conceived as *becoming.*[12] Therefore all light that is in

---

[12] Compare Eschenmayer, *Propositions*, 22ff: 'According to dynamical concepts, an equilibrium arises when two opposing degrees of reality act against one another. Here, however, we are only discussing a relative equilibrium, in which the effects of the two forces are thought not as cancelled by, but rather only as equal to, one another. An absolute equilibrium exists where two forces completely cancel each others' effects so that they are no longer an object either for mathematical construction or for the analysis of experience. We may think of an absolute equilibrium symbolically by way of the lever. As long as force and weight are distributed over the arms of a lever in some manner, then a calculation of the magnitude of motion also takes place, just as when I think of the force and weight as combined in the hypomochlion (fulcrum), the magnitude of motion is = 0. This is absolute mechanical equilibrium which, for mathematicians, is no longer an object. We can indicate a dynamic absolute equilibrium with the example of plus and minus electricity. As long as each works

contact with our organ is indeed such as remains in a state of *propagation.*

2) That the light from the sun is actually *merely the phenomenon*
88 *of a constant decomposition of its atmosphere* has been carried to a high degree of probability by *Herschel* (*Philosophical Transactions for the Year 1795*, vol.1).[13] According to the simplicity of means that we apply to the greatest and most widespread effects of nature, we may all the more extend this conjecture to all self-illuminating bodies in the cosmos, as many phenomena of its light seem to confirm such an origin; of which more below.

Since I have seen Mr *Herschel* himself, to make his hypothesis of the origin of sunlight more probable, appealing to the *propagation of light in our terrestrial atmosphere* (the Northern Lights, that are frequently so large and luminous, that they can probably be seen from the moon; the light that often in clear, moonlit nights, covers the sky), I am all the more strengthened in the conjecture that indeed all light is propagated by the vibration of an easily decomposable medium (see *Ideas for a Philosophy of Nature*, S.36).

---

on the other at a distance, we have the sensation of electricity, but as soon as the one passes over into the other, every expression of this fluid vanishes and becomes = 0 for experience.' [Editors' note *HKA* I,6: 297]

[13] William Herschel, 'On the nature and construction of the Sun and the fixed stars', *Philosophical Transactions of the Royal Society of London for the Year 1795*, part 1, 46-72: 'That the sun has a very extensive atmosphere cannot be doubted; and that this atmosphere consists of various elastic fluids, that are more or less lucid and transparent, and of which the lucid one is that which furnishes us with light, seems also to be fully established by all the phaenomena of its spots, of the faculae, and of the lucid surface itself.' [Editors' note *HKA* I,6: 297-8]

Since then, I have read *Lichtenberg's Meteorological Fantasies*[14] from the opportunity afforded by *Herschel's* hypothesis, and from this too it seems to me that the hypothesis is more confirmed than refuted.

3) It is now agreed that the light that arises in the combustion of bodies, is propagated from the environing air, and indeed from those parts of it that, from their efficacy in the advancement of vital functions,[15] have acquired the name *vital air* (*aer vitalis*). Already from the outset it may be conjectured that indeed *all* the light that we are in a position to create, takes its origin from the vital air.

In the work referred to, I have maintained that the new system of chemistry, as soon as it has acquired its due extent, could indeed develop into a universal system of nature. The present work should provide the test for such an extended employment of it. The discoveries concerning the properties of the *gaz oxygène* should long ago have made it clear that oxygen, if it is what it is currently taken to be, 38 will indeed be much more than just that. We have even begun to ascribe to the ponderable basic matter of the vital air the most extraordinary effects in nature. Against this, one remark, that strikes me as very true, will be made, that it is absurd to accord an in itself inert body of the sort that so-called oxygen is, such power. (See, for example, what Brandis says in *Essay on the Vital Force*, p. 118.)[16] Most important in this chemical discovery is the *constant coexistence of this basic matter with the energetic matter* manifest in *light*, so that until now one had at least every right to consider it as genuinely that matter to which nature opposes the constant effects of an *ethereal, universally distributed fluid.*

---

[14] Gorg Christoph Lichtenberg, 'Geologisch-Meteorologische Phantasien', in *Göttinger Taschen Calender. Für das Jahr 1798*: 83-120. *HKA* I,6: 298-9 cites Lichtenberg's discussions of the conditions under which variations are observed in the quantity of light from the fixed stars.

[15] Christoph Girtanner, *Anfangsgründe der antiphlogistischen Chemie*, second edition (Berlin: Unger, 1795), 61: '*Combustion* consists in the decomposition of oxygen gas by a body with which oxygen has a greater affinity than with caloric. *Burnable* or *combustible bodies* are such as have a great affinity to oxygen. During combustion oxygen is combined with the combustible body and acidifies it. The caloric previously bound to oxygen becomes free and bonds with the adjacent bodies; hence light and heat'

Since the vital air is a composite matter, and since all expansible fluids must be considered as composed of an original elastic fluid and a ponderable matter, we may here, since we find ourselves in the domain of a higher science, abandon the metaphorical language of chemistry and conceive the so-called acid-matter [*Sauerstoff*] or oxygen[17] as the *negative matter of the vital air* that in combustion is combined with the body, while the *positive* goes under the form of *light.* For brevity's sake we will designate light by +O, but oxygen itself by –O (provided that we do not thereby think of +E and –E).

If accordingly the vital air is the source of light, and –O is the *ponderable* matter whereby a *freely circulating,* highly elastic *fluid,* surrounding the planet, *limited* in its *motion* and as it were fastened to gravitating bodies, then the *old theory of Descartes, Huygens* and *Euler ceases, at least partly, to be hypothetical,* and perhaps, as *Newton* himself dared only conjecture, at the end of his *Optics*,[18] will be proven.

[16] J. D. Brandis, *Versuch über den Lebenskraft* (Hannover: Hahn, 1795).

[17] A. Lavoisier, 'Freier Auszug aus dem *Taité elementaire de Chimie à Par. 1789 mit Anmerkungen*', in *Physikalisch-chemische Schriften. Aus dem Französischen gesammelt und übersetzt*, vol. 5 (Greifswald: Anton Ferdinand Röse, 1794), 161: '*Vital Air*. Like all gaseous matters, the breathable part of our atmosphere contains caloric, to which something must be added to manifest this kind of gas. We may most appropriately call this acid-matter (oxygen, from oxus and geinomia), because through its bonding with most substances it produces acid; hence the vital air is acid-matter gas (oxygen gas).'

[18] Isaac Newton, *Optics*, Query 22, in Andrew Janiak, ed., *Newton. Philosophical Writings* (Cambridge: Cambridge University Press, 2004): 138-9. 'May not planets

What we call *light* is now itself the phenomenon of a *higher* matter capable of many more and other combina- 39 tions, and with each new combination takes on yet another mode of activity. Although it seems to be the most simple element, an *original duplicity* must nevertheless be assumed in light, or at least the light from the sun seems to be the sole cause that sparks and maintains all duplicity amongst the earths.

In light, as it radiates from the sun, only one force seems to govern, but doubtless as it approaches the Earth, another, antithetical matter enters with it and thus, since it is itself capable of bifurcation, forms together with that matter *the first principle of the universal dualism of nature*.

Such a dualism must however be assumed, because without opposing forces, no motion is possible. Real opposition is only thinkable, however, between *magnitudes of the same kind*. The original forces (to which in the end all explanations revert) would not be opposed to one another were they not originally *one and the same* (*positive*) force, which only acts *in opposite directions*. For this very reason it

---

and comets, and all gross bodies, perform their motions more freely, and with less resistance in this aetherial medium than in any fluid, which fills all space adequately without leaving any pores, and by consequence is much denser than quick-silver or gold? And may not its resistance be so small as to be inconsiderable? For instance; if this *aether* (for so I will call it) should be supposed 700,000 times more Elastick than our air, and above 700,000 times more rare; its resistance would be above 600,000,000 times less than that of water. And so small a resistance would scarce make any sensible alteration in the motions of the planets in ten thousand years. If any one would ask how a medium can be so rare, let him tell me how the air, in the upper parts of the atmosphere, can be above an hundred thousand times rarer than gold. Let him also tell me, how an Electrick body can by friction emit an exhalation so rare and subtle, and yet so potent, as by its emission to cause no sensible diminution of the weight of the electrick body; and to be expanded through a sphere, whose diameter is above two feet, and yet to be able to agitate and carry up leaf-copper, or leaf-gold, at the distance of above a foot from the electrick body? And how the *effluvia* of a magnet can be so rare and subtile, as to pass through a plate of glass without any resistance or diminution of their force, and yet so potent as to turn a magnetick needle beyond the glass?'

is necessary to think all matter as *originally homogeneous*, for only insofar as it is *homogeneous with itself* is it capable of a *bifurcation*, that is, of *real opposition*. But every *actuality* already presupposes a bifurcation.

Where there are appearances, there are already opposing forces.[19] *Natural science* therefore presupposes as its immediate principle a *universal heterogeneity*, and to be able to explain this, a *universal homogeneity* of matter. Neither the principle of absolute homogeneity nor that of absolute heterogeneity is the true one; the truth lies in the *union of the two*.

91 Without original heterogeneity no partial motion would be possible in the earth. For the opposing forces possess a necessary striving to *equilibriate*, that is, to set themselves into a relation of *minimal reciprocity*; consequently, were the forces not *unequally* distributed throughout the universe, or were the equilibrium not constantly *destroyed*, all partial motion would ultimately vanish from planets, and only a universal motion would persist, until perhaps finally even the inert, lifeless masses of the planets would collapse into a single heap, and the entire world sink into inactivity.

---

[19] Kant, *Critique of Pure Reason* (A265/B321) 'We are acquainted with substance in space only through forces which are active in this and that space, either bringing objects to it (attraction) or preventing them penetrating into it (repulsion and impenetrability). We are not acquainted with any other properties constituting the concept of the substance which appears in space and which we call matter.' See also Eschenmayer, *op. cit.*, 5-7: 'Matter is conceivable only by assuming two basic forces, and matter fills a space not through its mere existence, but by forces. Now since the empirical filling of space is given as endless difference in our intuition, but the multiplicity of a force can only consist in degrees, we may also consider these differences as degrees. Qualities are therefore degrees, and a degree of matter is any magnitude of proportion in which the attractive and repulsive forces stand one to the other. It is in this way that the dynamic is distinguished from the mechanical philosophy of nature.'

In order that the forces be unequally distributed throughout the universe [*Welt*], an original heterogeneity of the planets in each system must be postulated. There must be a principle that not only incites, but also, by continuous influence, sustains the conflict of particular matters on subordinate planets. Were this principle uniformly distributed throughout the universe, then it would soon find itself in equilibrium with opposing forces. It must therefore flow from somewhere else than, and from outside, the individual planets; in each system there must be only *one* body that always generates this principle anew, and dispatches it to all the others.

There is therefore no doubt that the *self*-illuminating bodies of the solar system owe this property to a quality that is properly their own, and which they obtain from the very beginning through a universal precipitation from the common solvent medium that precedes the formation of worlds.

To this extent, the view that the light from suns is generated from their own laps, still has a great deal going for it. Or should suns only be *light magnets*[20] for the universe, and all the light that nature generates from throughout all space be collected in them? Must there be, apart from planets and suns, a third class of bodies that are expressly determined to those processes by which nature generates ever new light matter (perhaps comets)? If for a moment we 39 think the world as finite, we must believe that from that point where the common centre falls, there emanates a constantly renewed and inexhaustible stream of positive matter. Is *Lambert's* argument that the planets that cycle within the centre of the solar system must be *dark*, convincing?[21] The star that in the sixteenth century suddenly appeared in Cassiopeia shone for one month more brightly than Sirius, and once it had arisen, as if from the void, gradually reduced in brightness, manifesting always weaker colours before finally disappearing completely; or was the star that Kepler saw at the start of the following century near the heel of the Ophiuchus, which demonstrated a constant change of colour (running through almost all the colours of the rainbow), but was as a whole *white* – according to Kepler's statements the brightest phenomenon in the heaven of fixed stars – perhaps, as *Kant* suggested, extinct suns reviving from their ashes, or were they the stage for another great process, by which nature generated light in the depths of the universe?

---

[20] Peter Joseph Macquer, *Chymisches Wörterbuch oder Allgemeine Begriffe der Chymie nach alphabetischer Ordnung. Aus der Französischen nach der zweyten Ausgabe übersetzt und mit Anmerkungen und Zusätzen vermehrt von Johann Gottfried Leonhardi*, 2nd edition, 7 parts (Leipzig: Weidmann, 1788-1791), part 4, 577: *light magnet* is the 'Proper name for Balduinic Phosphorous. This is nothing other than a combination of chalk with nitric acid. […] This phosphorous (which some… call *light magnets*, because it only lights once exposed to light at a distance) […]'. [Editors' note *HKA* I,6: 303.]

At least if, following Herschel,[22] the propagation of light in the sun is only an *atmospheric process*, then there must be a reason why at all solar atmospheres erupt into light propagations. Must we assume that originally some elastic essence from which nature propagates light, accumulates around the solar body, and that the existence of this matter in the atmospheres of subordinate astronomical bodies is due to the long influence of the sun alone? At the very least, the source of light in our atmosphere is not *purely* and *unmixedly* to hand.

---

[21] See J. H. Lambert, *Cosmological Letters on the Arrangement of the World Edifice* (Augsburg: Klett, 1761), tr. S. L. Jaki (Edinburgh: Scottish Academic Press, 1976): 'Should I, however, out in the common centre of the fixed stars, which together constitute a system, a body toward which they all gravitate, then I must give that body an enormous size and I must enhance its mass so much that even the most distant stars of the system would have considerable gravity toward it, because this is always proportional to the mass. Were I here to write a novel, I would then state that this body has either no proper light or only a very weak one. I would so arrange the world that the smaller dark bodies, like, for instance, the planets, would move around bright suns, but these again would orbit around dark bodies. For the suns would need no other light because they themselves possess so great a brightness, while the dark body can still sufficiently be illuminated by the suns which move closest around it.' [Editors' note *HKA* I,6: 303.]

[22] See note 13, above.

Who knows if suns are not surrounded by a completely *pure air*,[23] while a principle proper to planetary atmospheres prevents the outbreak of the propagation of light? There, in the sun's vicinity would shine an unchangingly pure light, unmenaced by any hostile principle. If it developed from the constant decomposition of a gaseous essence, we 39 would have to think this as provided with an extraordinarily high degree of elasticity, since as the largest masses of every system, suns, through the original transition from a fluid to a solid state, emit the largest quantity of elastic matters. To this, of course, is to be added the effect of gravity, which maintains the sun's atmospheric cover by intense compression, increasing its original elasticity to an extraordinarily high degree.

It is known that the intensity of light in its propagation is proportional to the degree of elasticity of the air from which it propagates. We experience this in great cold, when all fire burns brighter, sparks spread more quickly, electric light arises from the least friction, and even the earth's atmosphere at the poles radiates in electrical rays.

---

[23] Gehler, *Physikalisches Wörterbuch* part 2, 371: '*Gas, dephlogisticated, dephlogisticated air, non-combustible air, pure air (Bergman), Fire air (Scheele), artificial pure air (Keir), vital air (Ingenhouss), Empyreal air, Gas dephlogisticatum, aer dephlogisticatus, Aer purissimus, aer verus factitius, aer vitalis, gas ou air dephlogistiqué*: That component of the atmospheric air that makes it suited to sustaining fire and the breathing of animals.' [Editors' note *HKA* 1,6: 304.]

If then around the central body a gaseous essence emanates of so high a degree of elasticity that light propagation erupts unprovoked of itself, then continuous rays of light from these would spread in all directions and an ethereal sea would fill the empty spaces of the entire system whose midpoint they occupy, then indeed even spread into the spaces of more distant systems. For if the light developed never comes to rest until the gradually decreasing elasticity of its mass attains equilibrium, then the space it occupies at rest becomes proportional to its elasticity. But the degree of elasticity can increase to infinity, and be assumed to be as great as the explanation of appearances requires. Therefore the elastic matter that is propagated from the circumference of our sun can spread in a steady, unbroken stream to our atmosphere. The daily revolution of the earth will necessarily create the change of day to night, but not prevent the light from other, far distant suns from maintaining the continuum of their atmosphere with ours. Just as the hemisphere that we inhabit turns 94 towards our sun, so too will larger light rays penetrate it, and effect the phenomenon of *day*. A common medium fills our entire solar system; every individual planetary body will acquire as much light from the commonality as is possible in accordance with the quality of its materials, but nowhere in the whole planetary system is there a hiatus, or a space that is not filled by the common atmosphere of all.

If finally the fixed stars too yet belong to a higher system, governed from a common central body, then the atmosphere of this system will also be common. Thus the atmosphere of each sun is in contact with the atmosphere of a higher system, and all the light that is spread throughout the world is the common light of one *universal atmosphere*.

If meanwhile an original diversity amongst the planetary bodies exists, then the universal light cannot be *uniformly distributed*, but must radiate from all spaces of the world to the *suns*, and only from these to the planets.

Doubtless, however, it is not only individual, divergent rays that come to us from the sun, it is the *decomposed solar atmosphere*[24] itself that, as a constant whole, reaches even to us. The phenomenon of day is inconceivable as an accidentally diffused light. Since a source of light was formed in the vicinity of dark bodies, would this not at the same time have to be set in motion by the influence of the sun? The conflict of elastic matters in our atmosphere can only arise when our globe is transformed into a self-lighting body by an alien influence, becoming *sun and planet* at the same time, and thus combining heterogeneous properties in itself.

It is not enough, however, that the positive principle is only non-uniformly distributed throughout particular solar systems. If it radiates uniformly to a subordinate planetary body, a universal uniformity would soon arise upon it, that would ultimately terminate in a universal decomposition.

Light could not act upon the subordinate planetary bodies unless a force were extended over them that, excitable by light, must be primitively affinate to it. That however no enduring excess of this force of nature arises through the influence of the sun's light, is ensured by the world's very structure, by the change of day and of night, of the seasons, even by the form of the planets, since, to judge analogically in accordance with the form of our earth, without doubt wherever light rays strike most vertically (towards the equator), the greatest mass is accumulated; while where they more obliquely hit (towards the pole), they gradually flatten off.

---

[24] See note 13, above.

395 The *positive* cause of all motion is the force that fills space. If motion is to be maintained, then this force must arise. The phenomenon of every force is therefore a *matter*. The first phenomenon of the universal force of nature, through which motion is sparked and maintained, is *light*. What radiates to us from the sun (since it maintains motion) appears to us as the *positive*; what our earth (as mere reagent) opposes to that force, appears to us as the *negative*. Without any doubt, what bears the aspect of the *positive* is a constituent of *light*; with it, we simultaneously acquire the positive elements of electricity and magnetism. The *positive* in itself is *absolutely-one*, therefore the primitive idea of an inexhaustible *primal matter* (of aether), which, as if broken down in an infinite prism, extends into innumerable matters (as individual rays). All multiplicity in the world arises only by the various *limits* within which the positive acts. The factors of universal motion on the earth are *positive*, which radiates to us from outside, but the *negative* is what belongs to our earth. The latter, evolved from a positive force, is capable of an infinite multiplicity. Where a force of nature encounters resistance, it forms its own sphere, the product of its own intensity and that of the resistance it encounters.

396 The negative force is aroused only by the positive. Therefore in all nature, neither of these forces exists without the other. In our experience, as many individual things (particular spheres, as it were, of the universal forces of nature) arise as there are different degrees in the reaction of the negative force. Everything terrestrial has this property in common: that it is opposed to the positive force that radiates to us from the sun. In this original antithesis lies the seed of a universal world organisation.

This antithesis is postulated *absolutely* by natural science. It is not susceptible to an empirical, but only to a transcendental deduction. Its origin is to be sought in the original duplicity of our mind, which only constructs a finite product from opposing activities.[25] Those who adhere to experimentation know nothing of this antithesis, although they could not deny that their constructions of natural phenomena (for example, combustion) are wholly and utterly incomprehensible without such a necessarily postulated, if not empirically demonstrable, conflict. Those who simply propound this antithesis (for example, in the theory of combustion), expose themselves to the reproach that they invent hypothetical elements where they ought to experiment. This contradiction can only be settled by a philosophy of nature.

Experimental physicists are right to adhere to the positive, for this alone is directly intuitable and cognizable. Those capable of the larger view of nature must not be afraid to confess that they have *inferred* the negative; it is not for that reason any less real than the positive. For where the positive exists, the negative exists – and precisely because of it. Neither the latter nor the former exists *absolutely* and *in itself*. Both maintain a single, isolated existence only in the moment of conflict; where this breaks off, the two disappear into one another. Nor is the positive perceptible without contradiction; and when they boast of a direct intuition of the positive, they themselves presuppose the negative.

---

[25] See Eschenmayer, *Propositions*, 3: 'A remark is to be made here that it is only from the standpoint adopted by the metaphysician of nature that the necessary assumption of these forces can be proven and the duplicity of matters and forces which so many have introduced into natural science to explain the phenomena, justified. The theoretical dualism for natural science is actually postulated by dynamics, but we do not commonly observe its lineage. Thus we set acids and alkalis opposite one another, two electrical and two magnetic materials; hence Gren assumes a gravitational and an expansive force [...]. If we understand ourselves properly, then it is only in name that these materials differ, but are one in concept, and the assumption of such a dualism becomes necessary as soon as we analyse the concept of matter in regard to the category of quality [...] Ultimately such a dualism is deduced from the necessity of the original positing and oppositing, which are the conditions under which even the possibility of our consciousness stands.' [Editors' note, *HKA* I,6: 306]

This is what Newton found. As he established the force
7 of attraction as the negative principle of universal planetary motion, he does not deny, but rather affirms, that it is an *inferred* principle. He does not attempt to present a direct intuition of it, but rather *postulates* it, since not even the directly-intuited positive would be possible without it. He even acknowledges that if this principle were intuitable, merely apparent, then rather than being the actual force of attraction, it would have to be simply the illusion of a jostling, gravity-producing matter. That is, he shows that the demand to know something positive concerning the force of attraction is vain, and is based on inconsistent concepts.[26]

---

[26] See Newton, *Optics* Query 31: 'Have not the small particles of bodies certain powers, virtues or forces, by which they act at a distance, not only upon the rays of light for reflecting, refracting and inflecting them, but also upon one another, for producing a great part of the phaenomena of Nature? For it is well known that bodies act one upon another by the attractions of gravity, magnetism and electricity; and these instances shew the tenor and course of Nature, and make it not improbable, but that there may be more attractive powers than theses. For Nature is very consonant and conformable to herself. How these attractions may be performed, I do not here consider. What I call attraction, may be performed by Impulse, or by some other means unknown to me. I use that word here to signify only in general any force by which bodies tend towards one another, whatsoever be the cause. For we must learn, from the phaenomena of Nature, what bodies attract one another, and what are the laws and properties of attraction, before we inquire the cause by which the attraction is performed.' Eschenmayer, *Propositions*, 60f: 'I conclude with the remark that Kant, in the proof of the existence of an attractive force and the explication of its properties, has gifted us the key with which in the future the majority of the burdensome problems of nature may be resolved, and even the windows that were opened by the immortal Newton, when he accepted the attractive force as valid but not a priori provable presupposition for discovering the laws of gravitation, is satisfied by the proof of their existence that Kant presented.'

Let us from the first solemnly renounce a *physical* explication of that universal conflict of the negative with the positive principles, from which alone the system of nature develops harmoniously. And in order that our philosophy does not, by reason of its assertions, take second place to experimental physics, let us demonstrate, by a complete induction, embracing all phenomena, that its one-sided explanatory method actually comes to nothing without inner contradiction (the source of all life), and makes any construction of the first phenomena of nature impossible.

We will consider it proven:

1) That light *is the first and positive cause of universal polarity*;

2) that *polarity can create* no principle without having *an original duplicity in itself;*

3) finally, that *real antithesis* is possible only between things *of one kind and common origin.*

New Ecologies

Interview with Stephen Emmott, Drew Purves, Greg McInerny and Rich Williams

The many dire environmental warnings to which we have become accustomed all have their basis in predictive models devised by scientists. But what degree of confidence can we place in such models, and on what basis are they constructed? Scientists in the Computational Ecology and Environmental Science Group at Microsoft's Computational Science Lab, based in Cambridge, England are working at the cutting edge of environmental science, devising new methods to computationally model climate change and its effects. This work involves adapting statistical methods to reflect the particularities of the extremely complex and interconnected objects of biology and ecology.

In **COLLAPSE** *'s interview with four of the scientists working at the Lab, we discuss the new impetus that environmental concerns have imparted to ecology as a science, demanding a re-examination of its objects and its aims. They describe the delicate compromises that must be made between tractability, complexity, and the urgency of the problems which they are addressing, and the necessary confrontations with the historical scientific legacy involved in rethinking the biosphere. In this process, new models of scientific thought and practice are emerging.*

STEPHEN EMMOTT (HEAD OF COMPUTATIONAL SCIENCE)

COLLAPSE: Some may be surprised to see Microsoft involved in scientific research of this kind; could you explain the aims of, and the thinking behind, your team's work?

STEPHEN EMMOTT: When Microsoft asked me to join the company, science certainly wasn't natural territory for the organisation. That Microsoft is doing science – and in particular natural science – is the result of my convincing the people who run the organisation that science is set to become increasingly important to Microsoft, that Microsoft has the potential to make a significant contribution to the future of science, and that there are many potential benefits to Microsoft actually doing (in addition to just funding) science. The case I set out was as follows: Firstly, that there is every reason to believe that science (in particular natural science – or more accurately, a precise science of complex natural systems) is set to be the single most important driver of our times (especially in relation to environment, health, medicine, energy and the future of computing), the impact of which in the twenty-first century, from a societal and economic perspective, is likely to dwarf that of 'IT era' of the twentieth century. Secondly, that new kinds of software will power this science – enabling the realisation of unprecedented ability for predictive multi-scale models that permit 'Grand Challenges' in science to be tackled, large scale 'in-silico' experiments (e.g., future climate), highly novel data acquisition, analysis and visualisation techniques, and enhancing creative imagination in scientific discovery (interestingly, much in line with what Alan Kay originally envisioned in the 1970s as the potential of computing). Thirdly, that science is where numerous developments have come from that have shaped the company's business and technical strategy: the World Wide Web, the Browser, Object Oriented Programming, Search – and science is likely to be where future such developments emerge from.

C: You have spoken of pursuing a 'new kind of science' – could you elaborate on what you mean by this, and how your vision of it relates to that of Stephen Wolfram?[1]

SE: The last century saw an increasing fractioning of science, and 'natural science' has suffered most severely as a consequence of this. Biology, for example, is a discipline that has become divided into (to name but a few) cell biology, developmental biology, genetics, genomics, metabolomics, proteomics, structural biology, microbiology, epidemiology, 'systems' biology, mathematical biology, theoretical biology, cancer biology, population biology, stem cell biology, evolutionary biology, plant biology, ecology, neuroscience and now even 'ageing science'. This has in part been an expected consequence of the increasing specialisation of each of these various branches of biology, but it has been at some cost, and may well be looked upon by future generations of scientists as highly deleterious. I think this century will demand a significant (re)unification of science if we have any hope of making the kinds of advances that are now urgently required and that will fundamentally shape our society and our future. This will require radically new thinking, radically new ideas and radically new approaches in science in order to overcome existing barriers to fundamental advances in natural science – and it is precisely this radically new thinking and these new approaches in science that my Lab is focused on.

---

[1] S. Wolfram, *A New Kind of Science* (Champaign, IL: Wolfram Media, 2002).

As for Wolfram, when his book *A New Kind of Science* was published, both it and he were roundly criticised – unfairly in my view. I think this was because many focused on the narrow 'example' he focused on of Cellular Automata. I wouldn't call CAs a 'New Kind' of science, but Wolfram was actually making a much more important argument: that nature may not obey or be explained by existing mathematics – the 'rules' that have been (arguably) successfully applied to physical systems, most notably calculus and in particular Ordinary Differential Equations; and that therefore there is a strong case to be made that we need a new kind of science that is based on new kinds of thinking and a new kind of computational 'language' or approach that is likely to be fundamentally, radically, different to that of the 'first' (so-called) Scientific Revolution of the late sixteenth and early seventeenth centuries, which continues to dominate science today.

C: In our interviews we have spoken with those in your team who are working on ecology and climate modelling. Why can the kind of approach you have described make a difference specifically in the area of ecology? And what other areas is the lab working in?

SE: Rather than ecology being a priority, it's more accurate to say that the priority is to accelerate a precise, predictive science of complex natural systems – a new natural science – spanning biochemistry to the biosphere. The focus is on both developing new theory about complex living systems as information processing systems (e.g., cells as information processing devices and biochemistry as information processing machinery), and on novel computational approaches that allow the testing of such novel theory – including a scientific, computational and software framework to enable 'impossible' ('in-silico') experiments to be conducted (especially about the interactions between climate and ecosystems, where such an approach is really the only way to conduct experiments, other than the biggest experiment on earth – the one anthropogenic activity is currently conducting). Drew, Rich and Greg eloquently expand in different ways upon why our approach might make a fundamental difference in this area so I shall not attempt to do so here.

C: You have attended global summits on climate change to present this work. What is your impression of what happens when science meets politics?

SE: Well, we've seen recently all too clearly what can happen – with the fiasco of the COP15 outcome, the stolen emails from UEA CRU, the (thankfully unrealised to date) H1N1 flu pandemic issue. The list is a long one – I highlight just a few. My first quarter of a century in science has led towards the increasing impression that politicians of all persuasions are to a great extent guilty of using science (or the statistical summaries of science) much as a drunk uses a lamp-post – for support rather than illumination. On the other hand, one can't really blame politicians for doing so, since scientists are, on the whole, dreadfully poor at communicating science and its implications clearly and simply. Scientists need to do a much better job of informing the policy debate on just about every issue imaginable.

* * *

DREW PURVES (RESEARCH SCIENTIST)

COLLAPSE: It may be that some of the questions we are going to ask will seem naïve to a scientist …

DREW PURVES: This makes me think of Stephen Pacala from Princeton, from whom I learned a lot of science, but who also shaped my thinking about how to be a scientist these days. And he's someone who's always had a lookout for things that other people weren't doing, or which were said to be impossible, and he would just stick his neck out – which is part of his natural character, he's a very confident kind of character. He would just go in with the default assumption that "my naïve thought might just be relevant – let's see". And on several occasions, in the end he's been really listened to. Have you come across this 'wedges' approach to global climate change? It's the one where you say, over a given period of time, here's what we would emit if we were to carry on as we are, and here's what we can allow ourselves to emit if we want to avoid dangerous climate change. Then we look at the graph, and between the two there's this triangular difference. The area under that triangle is the total amount of carbon that we need to avert – the amount that we need to not emit. At the time, I think it turned out to be seven gigatons in total. So Pacala said, "well, let's visualise these seven units as seven wedges that add up to that big triangle, and then let's look at technologies and see how many wedges different technologies can give us." So, you know, more efficient cars gives us two wedges, and so on. And it turns out we've got fourteen wedges of technology right now. If we didn't invent anything else, we've already got fourteen wedges, and we only need seven. So we've got twice the capacity to offset climate change up to 2050. Then it gets harder, because the what-we-would-have-done is getting ever bigger, whereas the what-we-can-do stays still, if you see what I mean. After 2050, he says, you might need some more radical technologies, but even so, to be honest, you still have the other seven left – maybe that will get you another twenty-five years! So you are saying there might be seventy-five years worth of technology in place to solve climate change right now. So he just wrote that down and he gave it to me and said, "what do you think?" I said, "Well, okay, I guess ... " And it is now a standard thing in policy – people talk in terms of wedges, and it featured in David Attenborough's TV show – it had Pacala in it and his graphic with the wedges. It just shows you, to my mind, that a lot of the challenges we are facing are sort of 'nobody's business'. Everyone always thinks it's someone else's business, everyone always thinks that someone else is an expert on it. The fact is, no-one's an expert on climate change, or on solving global resource problems. The economists think "we can't do it because we don't know anything about biology or conservation or agriculture", but the ecologists think "we don't know anything about economics", and so on. So actually, a naïve approach, firstly, is valuable, and secondly, might not be as naïve as you think. When you ask these questions, they are probably the same questions that everyone is asking in that field.

C: And so what do you think of as being, on the broadest level, your contribution to understanding the problems – if not solving them?

DP: There are two sides to it, you see. Going back to the 'wedges' idea for climate change, we firstly need to predict how big the problems are going to be under different kinds of actions of humans, one of which is 'business as usual', where we don't think about it and just carry on; and then, knowing how bad the problems actually are, we need to find out, if we want to cap the problem at a certain level then how much do we need to do? So you are setting the size of the problem.

For instance, in climate change, what you want to know is, what is the relationship between the CO_2 emissions and climate change. You know, the way it is described in books sometimes makes it sound like a pretty simple process: you pour CO_2 into the atmosphere, and it's like thickening the glass, it warms up the earth. There is some of that, but in fact half of the CO_2 we put in the atmosphere goes into either forests or oceans straight away, so only half of what you put in even stays up there. But because oceans and forests are highly responsive to climate, as we change the climate the oceans and forests themselves change – they might suck up either more or less carbon. So actually, at the moment we don't know what the relationship is between the CO_2 that we put in the air and the CO_2 that stays in the air. We don't even know the relationship between CO_2 emissions and atmospheric CO_2. At first glance this seems almost ridiculous – surely you just put it in the air and it stays there; but it doesn't. Secondly, we don't know what the relationship is between whatever CO_2 stays up there and the climate. That's where a lot of my work comes in, because the largest uncertainty at the moment is the forests.

C: Before we discuss your work, by now, readers may well already be wondering how it is that we are assaulted by terrifying predictions about climate change and by directives as to what we must do, if we haven't even determined these simple causal relationships.

DP: People are talking more and more about this now – that it is really hard to convey uncertainty to the public. Up until recently people have been very wary of even admitting there *is* any uncertainty because it was in the balance, you know: Are international governments going to believe or not believe there's going to be a problem? Whereas I think that's done now, and we can be a bit more honest about the uncertainty. So, for example, in principle it would be just about possible to put more CO_2 into the atmosphere and for the global system to react in such a way that the end result of that was *lower* atmospheric CO_2. But frankly, that's extremely unlikely, it would be like a strange over-compensating mechanism. In reality, you can be sure about certain things: you can basically be sure that if you put more CO_2 into the atmosphere the atmospheric CO_2 is going to go up, even though it is not a one-to-one relationship. It is also very hard to imagine that the atmospheric CO_2 could go up without warming up the planet. So basically, you know that if we keep emitting CO_2, then atmospheric CO_2 will keep going up, and the planet will warm, and there will be other climate effects. The uncertainty is about *how much* the climate will change, and how quickly. But even the minimal predictions are still slightly worrying

– the minimal ones say maybe it will only be one or two degrees – but one degree, two degrees could be a big deal. So if you think about the spread of uncertainty it is really tricky, because if you just pay attention to the outer bounds of it, that could be really misleading. If you have a certain range, most of the predictions are going to say that it is somewhere between two and four, but some of the models will give you one and some of the models will give you six. It's quite hard to convey that sort of uncertainty. There are qualitative things we don't know about the subsystems, but I still think there are certain qualitative things that we *do* know, as near as you can know anything. It's very hard to imagine that the earth would overcompensate in some way.

The other debate that I think is really funny – I've had this debate with a relative who's really sceptical, and it's been really interesting bouncing things off him, and he said, "you know the atmospheric CO_2 is going up; how do you know this is caused by humans?" So, if you do an inventory of how much CO_2 humans are putting into the atmosphere and then how much the atmospheric CO_2 is going up, that's pretty suggestive; it's going up by less, not more, than it should, based on what we're emitting – that is, we are putting in more than enough in for it to be going up by the amount it goes up. So, imagine that it's not due to us: you would somehow have to imagine that all of our emissions are being perfectly soaked up by something, and then some other process is responsible …

C: A very circuitous explanation!

DP: Exactly. So, I do almost have to have two heads when I think about it: If you blur your eyes to the system, it doesn't look all that complicated really – I mean, you've got the atmosphere, you put CO_2 into it, there's not that much to it. But in going from that to any more quantitative predictions, suddenly there's a massive break in the amount of complexity that you need to think about.

C: If that 'blurred', high-level view already tells us that we have to reduce CO_2, what is the argument for even striving for a really detailed understanding of it? So that we can determine what's the least possible we need to do ...?

DP: The truth is that yes, that's been the argument. And I worry about this kind of stuff – about the role of this kind of science plays in the climate change debate – for those reasons. I think for a long time, essentially, you just had to persuade governments to worry and take it seriously. Now that job's done. If we could say, here is the exact response of the Earth's systems to different levels of CO_2, that would be fantastic. I guess that's what we are heading towards, but we are a long way from it now. And yet the policy that's really going to matter is being set right now. So there is this question in my mind: you could say – if you ascribe this type of rationality to global government – "I'm spending a bit too much every month, I want to get back to balance, I've got to cut down ten percent, I'm going to stop buying wine." And it's just like that: "you've got to reduce CO_2 by this much"; "Okay, we'll do it, thanks. We'll work out how to do it." Like they are completely rational and in control of everything, right. But in fact, is that the amount of CO_2 that they're going to reduce by, or will the reductions be set entirely by political and economic agendas? They may just want to do it as fast as they can, but 'as fast as they can' is determined by democracy and global economies, and all that kind of stuff. And if that's the case, I mean, look at the UK saying they want a ninety-percent reduction by 2050 and that we're going to carbon-neutral as fast as we can.

If that's the situation, then where does the climate modelling prediction come in? Obviously, there'd be a kind of reactive role for it: You could say, let's assume then that the world does do a ninety-percent reduction by 2050. Putting that into the model, let's see how much climate change, and where, and what should we be worried about. Look, there's a good chance that a chunk of Africa that is currently productive for agriculture would become a desert ... In which case it's just giving us warnings of things to come, if you like. Not the old kind of warnings which were meant to shake someone by the shoulders and say "you have to worry," but actually saying, "no, really, this is exactly what's going to happen, so we better plan for this." So it's giving a different kind of message, I guess.

C: And do you believe your work will contribute in the future to specific warnings, and thus legislation, of this kind?

DP: I would be very much hope so. I would almost say that if it didn't, I'd have failed. I used to think that the main role of my kind of work would be providing predictions of things that policy-makers care about, and how they would respond to different kinds of legislation. For example, if I ban GM crops, what does that do to agricultural productivity?

But more recently, I've come to realise that ecologists in particular have a big role to play in looking at global questions in a joined-up way, looking at all parts at once and what that means. For example, you encourage biofuel demand to offset fossil fuel emissions, but this increases the price of biofuels, which encourages Amazon deforestation in order to grow more biofuels, and that deforestation actually emits CO_2. That kind of tracing of effects, comes naturally to ecologists, but not to many policy-makers, I now realise. Of course, building models of these problems serves a dual purpose – it provides predictions, but also, in describing the model, you describe the problem in way that can really help policy-makers.

But there is another part of me, when I think about myself longer term, and what I want to do with the sort of science I study – the science of complex reactive organisms, especially plants. It says, maybe we just move on to a different kind of scientific problem, like improving agriculture, where you are thinking about plants and their relationship to the environment. And whether we could have much more productive crops, in particular crops that use less inputs – so, even if they are not more productive, they use less water and less fertilizer and things like that. As well as larger questions, sometimes I see things about poverty and I think, "Blimey, maybe I should get on board on that one." It's not like I come in every day and think, "Am I doing the right thing?" like some people do. I've got a lot of momentum. But I do worry sometimes about those things, and keep in mind that the science I'm doing has potential for those other problems too.

C: Returning to your current research, you said that the greatest uncertainty in modelling and prediction concerns the forests, and this is where your work is focussed.

DP: Most of my work at the moment is on forests, which dominate the global terrestrial carbon cycle. There are two projects, and they differ quite significantly in their complexity. One of them concerns the fact that, if you look at the carbon stock that is held in living trees, essentially, as the trees grow, they swell up and that carbon stock increases; what stops it increasing infinitely is that the trees die. So they die, fall over, and then it rots back into the soil and is emitted back out into the atmosphere. So let's consider the rate of tree death – or, to see it inversely, tree lifespans. Now, all the models assume that that lifespan is the same everywhere – that trees basically die one percent per year everywhere. Whereas if you take any kind of more detailed look at this, it will tell you quite the opposite. So, existing models have quite a nuanced approach to how growth depends on temperatures, and the same for rainfall, but the mortality is actually very fixed.

I've got a student at Leeds University who's been trying to get all these forest inventory datasets that have been taken for forestry purposes all over the world, knit them together in a database, and just basically observe the different rates of tree death in different climates, so as to replace that one constant with a function of climate and soil. By doing this we can genuinely help to constrain the future of the global carbon cycle.

C: What explanation can be given for the omission of that factor in the existing models? Is it simply a reflection of the history of scientific disciplines, what ecologists have been interested in (life rather than death)? Or did someone simply make that assumption at a given point and it was never questioned …?

DP: One of the things I have really tried to do is to look at all the parts that are involved in answering one of these questions to do with climate change. Traditionally what we've been taught in science – and to a certain extent it's become the natural tendency – is to do a jump from something that's already been done. So scientists build on each other's work, which of course is good sometimes; but sometimes it just misses an entire area, because you are only ever writing on something that's already been done. So you end up with more and more people studying the physiology of tree growth, and nobody doing death.

This was one of the big benefits to me of the global climate models. Because I was really sceptical about them, like a lot of ecologists still are – "oh, come on, it's too complicated, we're not ready". And it is kind of boring to put them together, because one hundred people have to work together, and it slows you down – I prefer me and a blackboard and a bit of paper – and we know the predictions aren't going to be reliable for a really long time, so you ask whether it's worth the effort … but, as I say, one thing that it really has done is that it's made us question what ecology is about. Well, it's about understanding the biosphere – and these big global modelling efforts have really given a shape to that problem. And there are now entire groups of people doing research and publishing papers on systems that by themselves just look so boring that no one wanted to know before. So people would go to the tropics and it was all the epiphytes, or the intricate relationships between ants and plants, and whatever else, whereas more often than not, they didn't measure the heights of the trees. And now we're doing climate change research, that really matters. In a lot of this work you are just hoping to have a balanced approach that in the future might help us to understand the whole thing. But along the way it opens up many new and very specific avenues of research.

C: A lot of the data that you have to work with was not gathered for the purposes for which you are modelling, which introduces a measure of historical dependence in the selection of the parameters and the setting up of the scientific problem. Consequently, as you're saying, this emphasises the need not to accept the legacy, but to reassess it at each stage.

DP: Yes, but we are just getting there. And in truth, it is partly a matter of time: You produce a lot of data for one purpose, and a bunch of other people say, "Hey, it's good for this different purpose." So there's a natural time-lag that operates through a sort of feedback. Another aspect of this is to do with different communities of people: By and large, NASA just loves putting satellites up, because they love building lasers and they love tracking satellites and doing new exciting things. So there's been a disconnect between the data-gathering and the use of the data; but I think now it is linking up a little bit more. I get the impression that NASA would realise now that they need to make some kind of rational argument – to President Obama, say –

for putting up a satellite to measure sea surface heights or something, and not just because, "Hey, we can do that, isn't it cool" – that actually it matters in some way to people. Still, in the majority of cases, even when people do their own experiments they typically end up analysing the model and asking questions they didn't anticipate when they designed their own experiment, so it even happens on a micro level.

Stephen [Emmott] talks about a 'new kind of science', and we're trying to find the broadest way in which to describe this. But I think some of the activities that make it different – the more day-to-day aspects – include a kind of turning of the scientific process on its head: Traditionally, we start with simple observations, move on to some sort of quantitative measures, and at some point we assemble it into a model and then we make some kind of prediction. Whereas we're now thinking that if you look into a problem for the first time, you might want to *start* by building a model, and then do virtual experiments on the model. We do statistics on the results of those virtual experiments, and then we ask at the end how well we did that virtual experiment. Then, we go and alter our virtual experiment – remember, at this point we are still not going into reality! – for example, we say, let's fertilise the plants halfway through the experiment, does that give me an increased ability to tell my hypotheses apart or not? If so, I'll retain that change to my virtual experiment. So there is this loop, an optimisation loop, and all I'm doing is optimising the design of an experiment, and it is only *after* all of that, that I actually go and do my experiment in reality. Whereas at the moment, even the people that do quite cutting-edge computational science in ecology still design their experiments based on 'gut instinct'; at the end of it they come in with all sort of bells and whistles, computational analysis, but typically they end up thinking, "I wish I had fertilised the plants half way through"! We're now calling this – thanks to Greg [McInerny] – 'joined-up ecology', the idea being that we join up all stages of the scientific process and move up and down it seamlessly. Going back to your question, it means we'd never again gather data without having at least one model ready to use that data.

C: In the case of planetary ecology, how is such a 'virtual world' designed to start with?

DP: On a grand scale, what we should be doing with Earth system models is to make them take in the entire Earth system – so that running the model simulates everything. We don't know how the real Earth system is built, but we have a sort of virtual Earth, which we build with our best guesses, to be realistic. Then we add a virtual sampling system, with virtual satellites and so on. We put that into the virtual model of the virtual earth and we ask, "How well does the virtual sampling scheme observe what we *know to be true*, within the virtual Earth?" We don't cheat – we don't tell the virtual sampling scheme anything about the virtual Earth, even though we know everything about it because we created it ourselves. Everything it knows has to come through the virtual data from the virtual sensors. Next, we can feed that data into a second virtual Earth model. Now we can ask how well the second model reproduces the behaviour of the first. Finally, we can alter the number of satellites and what they're measuring in a way that gives the second virtual Earth the greatest fidelity to the first virtual Earth, and then this is the plan of satellites that NASA needs to build. The point being that this whole (virtual) process is analogous to what we're trying to do in reality. We're trying to gather data, to make a virtual Earth that behaves like the real Earth.

C: People have a naïve idea that what scientists do is go out into the world measuring everything and then go home and write it all down and that's where they start. Whereas a scientific experiment is always constraining: you are always placing a frame over something and it can only tell you what you ask it. But to a certain extent you're saying that the naïve view has been true in the past – that there has been this process of sending satellites up, collecting data and not really knowing what's going to be useful.

DP: That's right, just as people would think. Then you look at all this data and you're trying to figure out what's going on.

I guess this is related to the use of Bayesian statistical methods: I pretty much just use Bayesian as a tool, but in ecology the philosophical implications have been much discussed. It's really a simple way to visualise the way science works: it's quite useful that you've got your current system of belief, and that really it is a sort of probability attached to any universe. So you can imagine a universe where tree death doesn't depend on temperature, but here there's a universe where it does, and here there's another universe where it depends even more on temperature. So you have all these different universes and each one's got a probability – how much do I believe that we're in universe *a* rather than universe *b*? Once you bring in your data it helps you make that decision about which universe you're in:

When I plot tree death against temperature I get this great big steep line, so I'm now really quite sure that I'm not living in tree-death-doesn't-depend-on-temperature universe. So you are continually updating where you think you are. If you knew it perfectly in the end you could say for sure exactly which universe you are in and then simulate your own universe perfectly. And that Bayesian process describes fairly well what scientists do.

C: Using that framework, then, what does your work tell us about the universe we are in that we didn't know before?

DP: The work that I've done that I'm proudest of is that I worked on a model of a forest that let you scale up from the rules that govern the growth and death of individuals to the long-term development of the forest itself – it was a scale-transition problem model. So the question is then examining that and finding a kind of model that works. That involved saying "I'm in the universe where that kind of model works against a real forest" – it was quite carefully tested to see whether it would actually work in a real forest. I've worked with a colleague at the University of Toronto on forestry, and he's looking at the problem of how you optimise any factor in a forest – whether it's yield, conservation value, carbon storing, biodiversity, or whatever. And we've looked at how the trees break up space in the canopy; whether you can understand how the trees' growth and mortality depend on the amount of canopy space that they capture and their size and age and so on. And so we found a lot of things out there: You get this U-shaped mortality rate where trees die quickly when they are young and old, but they die slowly when they are middle-aged, which of course is kind of like what humans do. And we worked out that the reason that the mortality comes down when they are young is that they are moving up the light gradient, so the environment is getting better, whereas when they are old it is worsening. And it turns out that if you double the canopy area you don't double the growth rate for an individual tree, so you discover new relationships like that, which seem to be common across all forests.

All of that does in fact constrain the universe of possibilities, because we didn't know it was going to be like that. And I think that once you know that you can really say a lot more about how forests work in general and how best to manage them.

But the mortality thing I'm really excited about. Again, we really don't know the relationship between mortality and climate; once we've done this work I think we will approximately know what it is and we really will have taken what Bayesians call a 'flat prior' – we really had no prior belief about temperature and drought and their effects on mortality – and created a much more concentrated posterior – we now think that trees die in *this* way in response to climate change. That posterior then becomes the prior for the next piece of work. So the next piece of work starts off thinking we're probably in this one of the many possible universes.

C: Such flat priors correspond perhaps to the type of 'naïve questions' we were discussing – they are factors that we have no beliefs about, because they have not been thought of as significant in the past. As such, considering them introduces new variegations and differentiations in the domain of 'possible universes'.

DP: Actually, I do have some beliefs – which if they're confirmed show how this work on mortality is crucially important in climate change: If you take a gradient across the Earth from a load of places where it is wet, the real difference between wet, say, in the tropics, to wet up north, say the redwoods or somewhere like that, is the length of the growing season. So you've got a twelve-month growing season in the tropics and it gets shorter and shorter as you go up. But it seems that trees die primarily in the on-season. So in the winter, it's almost like pausing a videotape: All the inputs through growth stop, but all the outputs through mortality stop as well. If most of the mortality occurs through pathogens and so on, this makes sense – it gets freezing cold so the trees can't grow but the fungi can't attack them either, so everything just stops. So I actually think that in wet places tree mortality is relatively unresponsive to temperature as opposed to somewhere a little drier, where similar kinds of patterns suggest to me that when you reduce the productivity through drought you actually increase mortality. And that makes sense again: they literally die from the drought. Things like that, just knowing if that is true, could change our prior assumptions about the way that water and temperature interact, and give entirely different predictions. And that immediately impacts the understanding of biomass over the globe: It says that if you reduce productivity by cooling a place down, it doesn't really have much effect because the gains and losses balance each other out; but if you reduce productivity through drying it out, it really changes things as such – the gains come down but the losses actually go up. So you've got this completely different effect.

And that affects predictions, so that, under a given scenario, like 'business as usual, anthropogenic emissions', I've got a prediction for global temperature and one for rainfall – and knowing these things could change that distribution. So, depending on which universe you believe you are in here, now, you get a different trajectory in the future, and if we can constrain which universe we are in, then hopefully that prediction will be constrained and that's what makes it more useful for forecasting climate change.

C: Understanding science 'idealistically' for a moment as being interested in the world for its own sake, it sounds like the advent of our understanding of climate change has opened up a whole new set of problems and questions which, as you were saying, were 'flat priors', which people didn't even think were particularly important questions, or which hadn't even been framed before. So has it opened up a lot of opportunities for studying what we didn't even know we didn't understand before?

DP: Yes, absolutely. You must have heard Donald Rumsfeld's phrase …

C: The unknown unknowns!

DP: I've been surprised how many emails I've had relating that to ecology, you know. People laughed at it at first, then they've started quoting it, thinking, "well actually …".

C: It's quite a profound statement, politicians have said far stupider things!

DP: Yeah, I think that's true. One of the things is that … I don't know, maybe there is a residual feeling of guilt amongst ecologists, because the truth is that there are plenty of ecologists out there whose immediate emotional reaction to the issue of climate change has been "Great! Because I happen to be the kind of person who likes to study the sorts of thing that feed into our understanding of climate change, and who can take the kind of approach that is valuable." You know, I'm a bit like that myself, because no matter how much I try, I can't get that much into the individual biology of species and things like that. Somehow, I can't get into the details – I'm a systematiser, I always want to look at eco-systems as systems, I'm willing to make simple hypotheses and go out there and test roughly whether they are right or wrong. A lot of people don't like that kind of work, because they would say, for example, "how can you say tree mortality has a relation to temperature? Malaysia is roughly the same temperature as Brazil, but Malaysia has got dipterocarps and Brazil doesn't – that doesn't make any sense!" And I say, "well, so Malaysia has got dipterocarps … we'll just have to find out if that matters at a later date."

So for me, there is a slightly guilty feeling of luck, in that my way of thinking is in many ways what is needed for tackling these issues; I think it's great to have a problem to go after, and then you can say, what do we need to do to answer that problem …? You know, we've got this 'shape' for our science, and the 'unknown unknowns', and of course those unknowns are really sort of low-hanging fruit: If you are the first person to take them seriously, then you can do something, you can feel good about it because its important, it feeds into this big issue. And I think that's why its important to have that 'other voice', like I said before, actually saying "erm … no". It's relatively easy to convince yourself that anything you do on this 'map' of what's important to do for climate change scientifically, is really achieving something that's great for mankind. But there is another voice that says, actually, where is the debate right now with climate change – what matters? Is the climate debate finished, because the world has signed up to doing something about it? – Job done, move onto something else like food security or the global economy, poverty and inequality or some other kind of complex problem. Or do we need to do a different kind of science – rather than a science that feeds into the understanding of climate change, or reinforces the warnings that there is trouble coming, do we need to ask different questions: How are we going to cope with climate change? Which regions are going to go through a qualitative change, meaning that we have to start thinking about human migration ...?

So I'm sure I'm not the only one who is on the one hand essentially worried about climate change and thinks it would be great if we averted it; and on the other hand thinks it's exciting because it's given us a great thorny problem. I guess cancer biologists probably feel the same way, sometimes they probably get excited about understanding cancer then feel guilty because actually it's such a horrible thing!

C: As we understand it, the latest models produced have made the problem seem worse than it had previously thought to have been – by building in all these interactions within the biosphere, the predictions for temperature rise look worse than in the simpler models.

DP: Yeah, that's right. With the forest ones, there was this famous result, it was one of the first Earth systems models to include truly reactive vegetation – before, they basically had the vegetation as a fixed thing. [Peter] Cox's team were the first people to say "hey, trees grow and die, and they might be taken over by grasses," and so on; and they put that into the model and warmed up their virtual world. And everything was fine for about fifty years (fifty years into the future, that is) and then something switched in the Amazon and suddenly it very quickly turned into a savannah, and all of the carbon that was in this great big forest suddenly went up into the atmosphere – so it acts as this great big turbo-charge, and in the model it released the equivalent of about sixty years worth of anthropogenic emissions in about ten or twenty years. So this was almost like a 'top-up', you know: we put it in, and the forest will match our CO_2. And that's the top line, if you look at the spread of the predictions which were in the IPCC report five or six years ago, their top line is exactly that, it's the Amazon collapse.

But then there is another model, to be honest equally believable, where as things warm up and the CO_2 increases, the Amazon trees just grow ever faster and store up ever more carbon.

Now, what I think is that, as we have added in these extra biotic feedbacks, there has been more freedom in the model – more things can happen, and one of those things is that there can more disastrous results. And that has been an important warning, I think, not to treat the system like a bath where you pour carbon in here and it comes out there. Actually, it's this non-linear thing, much more unpredictable. So that's been an important general message. But the question now is whether it's possible to constrain these feedbacks sufficiently to get back to a decent prediction! Or whether the only contribution from that work is a really general "hey, this is dangerous, you'd better …". Are these feedbacks simple enough that we can understand them sufficiently well to say, "right, now here is the prediction, and sure, it's different to one that we had before, but this one is right", or is the general message that Earth's systems are so complicated that we should simply not expect to be able to predict them? That's the other conclusion isn't it? Because there are always more feedbacks we could put in.

C: To have a complex enough model we would have to build another Earth.

DP: Exactly! If we could build another Earth that we could run much faster than the real Earth, it would be a useful tool!

C: Firstly, there is a problem of abstraction – to know which parameters need not be considered within a model. But, given the interconnected nature of the biosphere, in doing so one always risks neglecting feedback effects, and therefore leaving 'unknown unknowns' out of the picture. What you were describing before, with the virtual worlds, seems to be an iterated methodology designed to avoid that.

DP: It's interesting to hear you take that very abstract, general view – talking about the Earth model like it's any other complex system. I think that is actually very helpful when we're thinking how best to improve these models. Like you say, we can use general principles to help us. Sometimes, being deliberately blind to the reality, and the details, can be really helpful.

To be honest my instincts are: Yes, the feedbacks are there, but it shouldn't be that hard. We just need to do them correctly. There will be this initial chunk of effort, and we will bring the uncertainty down by about ninety percent, and then yes, you could spend the rest of your life doing the other ten percent. But I feel like, if we could approximately know the things that we need to know …

There is a project now for instance, AMAZONICA,[2] which is a bunch of people, some of whom I know, who are all just focused on that one issue of 'will the Amazon collapse into a savannah or not under climate change?' If they answer that question, they will have taken the single biggest uncertainty out of the Earth system models overnight, really. And, you know, that's maybe a big fifty percent, and if you do fifty percent of what's left with a similar-sized project, you might get there. But then at the same time someone might say "hey, you haven't put in the boreal permafrost lichen feedback in there" … So, while someone is constraining the Amazon, someone else might be increasing the uncertainty somewhere else!

C: All this might lead someone not conversant in the field to ask what kind of 'certainty' we are talking about here. It seems difficult to accept that we could ever reach the point of having any degree of confidence.

---

[2] See http://www.geog.leeds.ac.uk/projects/amazonica/.

DP: And we won't know for sure until it's either happened or not. People have said similar things elsewhere in the history of science, you know, 'why the guess?' 'why the prediction?'. And to be honest, I don't really believe it. I couldn't exactly prove it.

C: But to remain a scientist, you have to retain some faith in the predictability of nature!

DP: Exactly. So, here is an interesting example: there is a diagram that people often see. It's this chart that has temperature horizontally, rainfall vertically, and it's got zones drawn on it, and each zone corresponds to a different kind of vegetation. Now that basically applies all over the globe. So if you know the average temperature and the average precipitation, you can essentially say what kind of vegetation will live there: grassland, savannah, evergreen forest, deciduous forest, and so on. And that happens in South America, North America, Africa, Malaysia. By and large, all these different places have different plants that have evolved separately, but the relationship between climate and vegetation is the same.

Another example I really like which I find incredibly compelling is this weird kind of shrub: It's a bit like an aloe, and what it does is die off every year and the new vegetation grows back on top the old and it ends up looking like a great palm tree kind of thing about twelve feet tall. You find them in the high tropical Andes – cold, but on the equator. These are unusual places, they have huge diurnal swings of temperature. Now, if you go over to Mount Kilimanjaro, which is also a tropical, high mountain, you find shrubs that look exactly the same but they have no evolutionary history in common at all. Another example is succulents like cacti: you've got old and new world cacti, they look really similar, they do similar things, they have evolved similar tricks to do with water. You find them where you have two wet seasons a year, that's the rule. Wet-dry-wet-dry, every year. Not wet-dry once a year – that gives you something else, maybe grassland.

So the new world and old world cacti look really similar, but have no common evolutionary history. What this tells you is that there is predictability out there in ecology. For me, I see a lot of signs of determinism – if you know *a* you can predict *b*. Even if prediction does not work, we can simple observe that *a* and *b* are highly correlated in effect, so the shrubs are highly correlated with high tropical environments and so on. So for me, it says that nature isn't this unpredictable, wacky thing. And if that's true in this context, why shouldn't I be able to take something like a tropical forest and warm it up and dry it out, why shouldn't that be predictable too? So that's essentially what we are looking at when we look at these diagrams.

If I didn't see that kind of predictability in nature, I think I would be having major thoughts about being in ecology. You know, even if it was predictable on some micro level… You must have thought about this whole Creationism/Darwinism thing, where a lot of people say Darwinism isn't scientific because its not predictive, all it ever does is explain things after the fact. Whether or not that's true, I think that if there wasn't this sign of predictability in ecology that would be all that we were doing, we would be saying, well, we've got coalescent shrubs in the high tropical Andes, they are the only place on earth I'd find them, I'd like to find out why, and somehow with enough effort I would be able to unravel the fact that there was an original aloe that didn't have a stem, and then one evolved that grew up on a stem, and so on. But to what end? That's literally just uncovering a story, a kind of archaeology, if you like, rather than ecology. Whereas to actually say there is this determinism, there is this pattern, *a* leads to *b* here, *a* leads to *b* here, so why is it in general that *a* leads to *b*? That's much more scientifically interesting.

C: If we simply deal with correlations, we ignore a large part of what is important for the operation of biological systems – which includes contingent things like contiguity, the fact that a certain species is separated from a habitable region by an ocean, and so on; but here you seem to be saying that it is valuable sometimes to abstract from the actual contingent conditions of the Earth, and look at the hard-and-fast rules in nature quite apart from the way in which they have, in evolutionary history, played out …

DP: Sometimes, yes. More generally, I'd say it's a case of working out for which processes knowing the history helps you to predict the future, and for which processes working out the history is just a waste of effort.

C: You said that you can't get interested in biology on the level of species. But the relation of your work to biology seems an important question. What status does a thinking of these questions on a global scale have in relation to biology? Is it a kind of 'ecological physics' which abstracts entirely from biological knowledge?

Although your work combines high-level modelling and 'on-the-ground' research, because ecologists have to think on a global scale, it must be difficult to connect that back to any of the things that we know deterministically on the biological scale: it's almost like there is a disconnect between the two things, that you are talking a different language.

DP: I think to some extent that is true. I think if you pushed most ecologists they would say the same thing, that's its really all about taking what we know about individuals and maybe less than that, like physiology, scaling up from there and working out what gives you these patterns. There are two ways that people talk about ecology: It's either the study of the interactions among organisms and their environment, or it's the study of the distribution and abundance of organisms. You really need both to define ecology, because what it should be doing is explaining and predicting the abundance and distribution of organisms *from* their interactions with each other or their environments, that's what it's about really.

I think that's what we want. I see the patterns at large scale and you are right, with some of the things that we do, like this work on mortality, we just find a pattern in mortality against climate, and use that pattern in a model. Everything in there happens from this kind of large-scale 'blur our eyes' standpoint. But really, more exciting for science is to ask, how do we get to this pattern from what we know about the way things interact? So, as I've explained, we would look at trees and how they interact with different species, how they put carbon into trunks and roots, and how from that we can explain why trees die more slowly when it's cold …

C: As you've said, before the modelling process begins, before you do these global-scale models, you already have some intuitions of what might be the case and what is important to look at, and those come from thinking about actual trees, individual trees, and their interactions.

DP: Yes. That's exactly right, you come from both directions really. Sometimes you'll look at the pattern and you will instantly have a little guess about what it is about the interactions that is causing that pattern, or sometimes the other way around, you know about the interactions and you have a guess as to the pattern. This comes back to 'joined-up science' again.

I'm working with Greg on this whole modelling effort looking into the distributions of organisms, which are highly correlated with the environment – it's another sign of determinism. So it implies that if you change the climate, this distribution is going to change. If you always find beeches when the annual temperature is between *a* and *b*, and, owing to climate change, that annual temperature band moves across the map, you'd expect the beeches to move, right? But a lot of the models people have used to predict that movement are simply incompatible with any of what we know about how organisms interact, and that just seems, to Greg and I, the wrong way to do the model.

Their models, for instance, say that if you removed all the tree species on earth except beech, the beech trees would just stay where they were. And any forest ecologist will tell you that no, of course if you remove all the other trees on earth, the beech trees will just spread into the vacated zones. They'd be pushed back through competition. And if your model doesn't do that, if it doesn't show that if you remove species then the remaining species move into the remaining space, then there is something wrong.

So, Greg thinks a lot about these sorts of things, more deeply than I do, I tend to rush in and say 'let's see what we can do'. He really wants to get a set of models that are consistent with the theories about the way organisms interact or the theories about what really causes the distribution of particular species; he wants to work that kind of theory into this applied modelling which describes how they are going to respond to climate change.

So, firstly, I think there is a disconnect; but secondly, it's all about removing that disconnect … as much as possible.

C: Do you sometimes have moments when you are absorbed in work, in the technical work of building these models, and suddenly have a flash of realisation that it is actually this planet, and all of our lives, that your work is talking about – or does the reality of what you're trying to model disappear beneath the process of doing the work? One would suppose that it would have to, otherwise your job would be extremely stressful!

DP: Yes, I very much do have those moments. It's been over ten years since I started my PhD, and in that period I've learned a bit about plant ecology, done a very few bits of new work, and have maybe sharpened my plans about what to do next. In the meantime CO_2 has risen a lot, there have been wars, people have starved to death, and a species of dolphin has gone extinct. We'll never get it back. So yes, it's a good job that most of the time, I'm lost in a much more abstract world.

C: Finally, if we were to run a model where humans actually achieve the ideal and become 'carbon neutral', do we know what ramifications that (unlikely) scenario would have?

DP: We have a range of emission 'scenarios', some of which are very optimistic. I'm not sure whether there is one where we achieve the ideal – but there should be. You would think of course that the result would be that on that great day when we stop emitting, everything stops changing. But there's no way that would happen. The Earth system is so complex, has all these time-lagged effects, that it would keep changing for centuries anyway. And that's before we consider the many other kinds of impacts human have on the Earth system, quite apart from carbon emissions. It really is, unfortunately, very very scary when you think about the next thousand years of the unremitting effects of humans. We're going to be staving off one disaster after the next – hopefully.

* * *

GREG MCINERNY (POST-DOCTORAL RESEARCHER)

COLLAPSE: Could you tell us what is involved in the work you are currently doing?

GREG MCINERNY: At the moment I'm working with what are called Species Distribution Models (also known as Bioclimate Models, Climate Envelope models or Niche Models). Basically, this involves trying to produce a description of why populations occur where they do rather than elsewhere. For instance, an organism has tolerance limits for temperature, so we may be able to describe those in a model. The organisms may also have tolerance limits for light levels, so we can include that extra gradient in the model. And so on, with factors such as rainfall, the occurrence of frosts.

Because there is variation in the environment across the Earth (for example in temperature and availability of light) we can begin to get an approximation of where things can live across the globe. These are the basics of a Species Distribution Model – a mapping of a species' 'success' across variables that can describe its geographical distribution.

These are quantitative models developed from data using statistics, so there are lots of considerations with regard to how the statistical assumptions match up with the biological assumptions. The hope is that if you get the quantitative description right, you can use that model to make predictions – for instance, in relation to climate changes. If the spatial distribution of temperatures is going to change, we can make basic predictions about where organisms will be in the future. Will Britain have a Spanish Flora in a hundred years' time?

Up until now most of the models have been merely statistical descriptions, usually based on correlative relationships between observed presences and absences of a species, and the 'climate' variables that have been measured as part of that. However, when such models are used to make projections for climate change or for a different area of the earth, the results don't necessarily hold much weight.

This is because the assumptions of the statistics aren't explicitly biological, and in fact implicitly ignore most of our ecological understanding. So Drew and I are trying to create 'next-generation' Species Distribution Models where a bit more biological and ecological understanding goes in at the beginning – for instance, competition between species. The factors determining where species can occur include both abiotic and biotic factors.

I really got interested in climate change during my PhD because I was investigating what the important factors were for climate change responses and how those factors might interact. The simple conclusion was that more processes are important to describing climate change responses than we actually study now. And, importantly, that the novel interaction between these processes can lead us to new understanding. Climate changes have occurred in the past and these events could have had a large influence on why we have the biodiversity that we do today, and what we will have in the future. Once you accept the importance of these interactions between processes during climate changes, then you need to study things in a different way. A mechanistic way.

In the simplest sense, a statistical model just draws information from the raw data. So if you've got *x* variables and your observation data, you choose the ones that you are interested in and then you do some kind of regression looking for correlations between the variables and the observations. In that way, you discover a fact about the correlation between variables, but there is no causal information whatsoever in there. What we want is to include the causes – the important processes. Then the models will be valuable to the research community to develop the knowledge and understanding that can really inform policy.

C: So, with a statistical model in physics, say – where the fundamental causal mechanisms are known – the predictions need to be supplemented with that knowledge in order to give a full understanding; but what has been lacking so far in biological computational models is knowledge of those causal mechanisms. Furthermore, one would assume that in the biological realm, such mechanisms may not scale smoothly, and may be subject to unexpected discontinuities under certain conditions – and indeed this is precisely what we need to know in order for the models to be useful: In effect, we need to define a kind of behavioural landscape that tells us where statistical correlations between variables remain constant, and where they break down and in what way. And that's precisely the task of 'eco-logy' here – supplying a logic of the living environment to supplement this raw data-processing.

GM: In principle yes, understanding the mechanism is the key to developing the most useful statistics. In ecology we know an incredible amount about the mechanisms but we don't necessarily go about developing models in the best way, based on this knowledge. We are a relatively young science compared to physics! We do know a lot but don't necessarily implement all of it.

But also we are very different from physics – dealing with units that are highly variable, that can change (through plasticity or evolution) to new forms, and that live within an environment that varies through space and time. That makes it far more interesting than physics!

If we could develop the 'behavioural landscape', that would be a good proximate solution to modelling. We would be able to make predictions based on those correlations. But that model may in turn be specific to correlations that occur in a certain set of conditions. If we change the climate then during climate change new processes may become more important in describing a new set of correlations. So a purely correlative model becomes a second choice.

That is where the methodology of Species Distribution Modelling begins to break down, because it was *descriptive*, and we need something that is actually *predictive*. And yes, that is exactly where the ecology should come in.

C: The model needs to account, not only for all of those different variables and their correlation, but for the causal interaction between variables as well.

GM: Yes – if you strictly follow a principle of parsimony when you are building your models, you would go for the simplest explanation. But there are a variety of ways in which you can judge that 'simplicity': Is it purely statistical simplicity, or simplicity with regard to the topic being studied?

Ockham's razor would need to be used in a different way if you are to build a model that is applicable to a different set of conditions as well. So in the case of Species Distribution Models the data you have is from a 'stable' climate, but from that you want to build a model that is applicable in a changing climate. You have to begin with a set of requirements that are known to be important before you approach a problem – for instance a set of important processes and their relationship to climate – rather than being a bad statistician and just looking for statistical interactions. If we take the challenge on appropriately and in a biologically-meaningful way then we could have a model that can cope better with situations such as climate change.

C: Is there a conflict between this attempt to build in all the complexity of the empirical biological world, and the need to build a model that is actually tractable, from which are going to be able to extract something of use? Is there a trade-off there?

GM: Totally. This generates conflict between what we might think occurs and what is actually tractable in a model in a rigorous way. We need models that are rigorous so that we can inform, but also tractable so that we can progress.

The trade-off comes in many forms. Firstly it is important to bear in mind that the set of requirements will depend on what the question is. At the moment the set of requirements is very large with respect to climate change prediction, because we haven't been able properly to explore what is actually important as we don't yet have the models. Once we have those models there may be some approximations or simplifications that can be made.

But if we were only interested in 'stable' climates then we could be less explicit about some processes. These are trade-offs involved in making models that are as simple as possible but as relevant as possible.

We also have to make models that are implementable and within which the statistics can actually work.

For instance, for each part of the model we are going to have parameters that control the strength of effects of different processes within a model. The more complicated the model, the more parameters we need to evaluate and the more combinations of parameters can potentially exist. Parameters can trade off against each other, so a high value in one can compensate for a low value in another and vice versa, so the interpretation of the theory has to acknowledge the statistical methods.

Also, the more complicated models get, the more difficult it becomes to analyse models so as to attribute cause and effect. We also have trade-offs defined by the amount of data we have: With low levels of data, as is generally the case in ecology, we are restricted in what we can actually parameterise.

A good way of exploring the challenges of model building is the generality/precision/reality trade-off described by Richard Levins.[3] A general model would apply to many species but would as a result be less realistic for specific species or situations. We could make highly precise models but that may come at the cost of generality as it becomes so specific. To build a realistic model might reduce your ability to be precise as we lack appropriate data for the realistic mechanisms and have to draw out information in a less precise way. This is one of the reasons why ecological science always challenges you and requires a bit of a philosophical bent.

One of the components of our Next Generation Species Distribution Models is investigating how you could incorporate competition into a model and make it tractable.

---

[3] R. Levins, 'The Strategy of Model Building in Population Biology', in *American Scientist* 54 (1966), 421–31.

C: Competition for resources between species?

GM: Yes – So, say you have six species of grass, which are using reasonably similar sets of resources, then in your model you could have a matrix which statistically describes how strong the interaction between species A and species B is, between A and C, and so on until you have the full matrix. For all the species described, you will have a value for each of those pairwise interactions.

That can make considering large communities of species difficult because the matrix grows non-linearly. If I have two species the matrix would have two parameters, the effect of A on B and B on A. If I have three species we need the effect of A on B, A on C, B on A, B on C, C on A and finally C on B. That's six parameters. If it was describing interactions between ten species, the matrix would have to contain ninety parameters. You can see that the parameters don't scale linearly with number of species that you consider, as you would like them to.

What we've done is to use ecological theory to make that relationship between number of species and number of parameters linear. One way is to describe interactions in terms of effects and responses, so A has an effect on other species and a response to other species. Field experiments have shown that this can be a useful way of describing the competition and allows us to make the model more tractable.

We can add more detail by describing in the model species traits that define competition – for instance, a plant's rooting depth or its height might define competition for water or light. Then we can describe competition in terms of the difference between traits. This is similar to an effect and response model, but the model includes description (and so assumptions) at a greater level of detail. We can go on to further levels of detail but we might need more data to do so.

In this case we find that ecological theory actually makes that model more tractable than the statistical interpretation of the problem. Our parameters scale.

The ecological theory reduces, not the amount of data, but the complexity of the model that you produce: To make it tractable, the amount of parameters in that model has to be as small as possible, really. So on the one side you've got knowledge of what you should be putting into the model, all of which you need; and on the other side you've got the practical nature of actually modelling so it has to be as small as possible; and this produces an appropriate solution for the task.

C: So, not only is the theoretical framework crucial to building models that answer to the complexity of the domain, but it can actually *reduce* complexity as compared to a purely statistical model. One could expect this, since the very notion of looking for statistical correlations involves a deliberately 'blind' approach to the data. Is this a novel approach because modellers have been unsure about the ecological theory they should employ? One could understand such a reticence, since ultimately the accuracy and the usefulness of a model would depend on the ecological-theoretical framework that you use.

GM: Yes, theory is crucial. Theory deconstructs the world into useful abstractions, general models of mechanism. Then, given the parameters that are realistic, we can make a prediction of the outcome. If we were only able to interpret the world in a correlative way humans wouldn't be able to accomplish all the amazing tasks that they do.

It's basically the power of explanation: We can say that lots of factors are important to an event, and give a precise answer that relies on complicated interdependence between the factors, or we can describe how those factors are mechanistically related to each other, in which case the interdependence may actually be smaller. We are reducing the problem through theory.

But explanation can be complicated, so some non-mechanistic correlations are very useful and may provide a simpler solution. The trade-offs in model building return and then we have to think about task-orientated solutions to the problems rather than an omnipotent model that reconstructs the entire world.

As to the second part of your question, about the selection of which theory to use, this is more about the human condition: Theory is sometime caricatured as the domain of the 'thinkers' – mathematicians, physicists – rather than the 'doers' – the people who apply models to practical situations. There is an incredible amount of theory out there but isn't necessarily applicable in practice. So we need to think in a joined-up way and develop ecological theory within the context of statistics, and statistics in the context of theory. This can be an unenviable task sometimes, as you may be less productive in doing so, and you may need to invest much more initial effort in being technically and conceptually literate in more techniques, ideas, skills, and so on.

Also, the theoretical and statistical communities can be separated socially – even at conferences theory sessions may be specialised and populated by theoreticians. We need more democratically-selected theory and we need to increase the interactions between increasingly specialised communities. So the short answer is that this reticence can exist because it is hard to mix theory and stats; but it should be recognised that we can shift the culture of our science to make it easier. We are all theoreticians whether we like it or not, so we need to increase the dialogue.

C: We're talking, then, about the effect of a contingent institutional history concerning the disconnect between computational science and ecological theory?

GM: From the more institutional and historical points of view there are choices that are made during science's development that are driven by the personality of individuals and groups and the natural growth of scientific communities. You only have to look at the names of models, theories and philosophies to see that individuals have had a large influence on a 'punctuated' development of science. This is especially so where a new scientific revolution occurs, such as that around computers, and when new subdisciplines emerge. Personality can play a large part in how new groups engage with each other. There is some trade-off between establishing a new approach and not getting swamped by previous approaches, whilst also maintaining a useful dialogue.

But it is a 'disconnect' found more widely across ecology: Field ecologists use theory in a very direct way but don't always recognise it as theory. There is a lot to be gained by extending our joined-up view of ecology, as it informs the generation of good experiments, which in turn inform better theory. In many cases, theoreticians are the most computer-literate and appreciate the value of this interaction. So the real challenge is to enable a larger dialogue with the broader community.

C: With this in mind, and to start again at the beginning, maybe you could explain what you understand by 'ecological theory'?

GM: Theory is a simplification of the world that allows its prediction, i.e. an explanation. This is a very broad interpretation and takes in mathematical or syntactic formulations, but also verbal and visual formulations.

'Life' is a complicated multi-scale system, so theory requires useful abstractions. For instance 'population growth rate' has got ecology a long way so far, but is an abstraction that takes in survival, growth and fecundity of a population. These abstractions may be useful in some cases but, again, more detail may be useful elsewhere. In this case a joined-up approach would consist of theory that is based in abstractions that are measurable in field or laboratory experiments, or that are retrievable from data.

Ecology doesn't really have laws like physics does in its construction of theory, so it's an understanding of the actual mechanics of how ecological interactions would work. You could go on all day and all night describing the processes of life in lots of detail. But there are certain things which field, laboratory, simulation and mathematical experiments have shown to be useful simplifications of models, showing what is best left out.

C: So any *applied* ecological theory is essentially *not* a complete account of causal interaction in the domain, but involves primarily a principle of abstraction.

GM: Definitely, this is where the boundaries of scientific disciplines are usually formed. And in some cases these boundaries are useful – but in others we need to make cross-cutting abstractions. Population Ecology generally considers the world from the organism above. This obviously leaves out most of biology. Theory is a question of understanding the system in the appropriate way.

C: And you suggested that the level and nature of this abstraction is determined by experimentation – so experimentation on the ground sets the parameters for modelling?

GM: Yes and no. Not all experimentation is going to be directly applied in a quantitative model. It may highlight new facts, mechanisms, and so on. It is more about exploration. This might set the parameters and formulation of modelling, but modelling might reveal that more useful model formulations are available for that same process, and then experiments may need to address different questions and field observations may be ideally made in a different way. Then there needs to be feedback with experimentation.

It's just how science progresses, but we need to recognise that the feedback between the theory and experimentation comes from an appropriate dialogue between sub-disciplines. For instance the statistics used by an experimenter may not be useful to a theoretician, and the abstractions used by a theoretician may be useless to an experimenter. This is of course a caricature but the principle holds true.

C: This suggests that, short of a purely statistical approach, you can't have a mathematical model that doesn't somehow rely on some theory-based filtering of what goes into it, this filtering itself perhaps having been influenced by previous empirical experimentation … A prior selection, an abstraction, always sets the scene for any scientific work – Philosophers will recall Immanuel Kant's famous comments about Galileo's 'inclined plane' experiment: 'reason has insight only into that which it produces after a plan of its own, and […] it must not allow itself to be kept […] in nature's leading-strings'.[4]

GM: The way I always think about it is with reference to 'population thinking'. Ernst Mayr said that an overlooked 'benefit' of Darwin's theory to science was the abstractions he made in thinking about the system. Darwin saw variation within populations and put that into his verbal model of how the populations worked and then ran his thought experiments.

Some variations could be more successful than others in surviving or reproducing, and so give rise to natural selection, a natural process. So Darwin showed that once you've thought about the right sort of 'population' of variation, in this case very literally variation in a population, then the dynamics can come out of that system. In his case natural selection could occur, whereas it could not occur in previous models because the variation is abstracted out. A lot depends on abstractions.

---

[4] *Critique of Pure Reason*, Bxiii

'Population thinking' gives clarity about what you want to include in your model. A lot of the time it has a single form that you'd actually go for because you are interested in a certain kind of dynamics. For instance you might need to acknowledge that there is variation in ages within a population and so abstractions on age need to be assessed. The variation doesn't need to be heritable, you just need to get the correct units. For instance, using numbers of individuals within a population can give very different results to using numbers of individuals of certain age classes within a population.

In the case of natural selection, evolution wasn't possible theoretically until Darwin got the abstractions correct. Darwin's great innovation was to give importance to variation within the species. For instance, if there is variation in different grasses then the small ones might get selected in certain environments and the big ones might get selected in other environments, but if there is no variation, that population's going to have no change in its average no matter what environment you put it into. Now, you could easily think that some other trait was important in your model – it doesn't necessarily have to be variation – but, say, if you are creating a model of a species' whole geographic distribution, it isn't going to move through space in response to climate change unless there are parts of the model which actually incorporate movement or dispersal of organisms in some way. It's that basic and fundamental.

C: Obviously, there is a 'selection' at work within scientific ideas themselves, according to the insights they yield.

GM: That's the progress of science! But it is important to recognise the correct form of selection. One of the best ways of putting it, I heard from Rich Williams: The ideas have to be agile.

C: So, the aim of Species Distribution Modelling is to try to understand why species end up in one place rather than another; and that's going to be important to understand species' reaction to climate change.

GM: Yes, indirectly – it is understanding abundance and distribution that is of fundamental importance: If you reduce down all ecological questions they would come down to 'why is what where': Why things occur where they do and in what amounts – which obviously requires understanding why they don't occur where they don't as well. If you can predict abundance of a species, then you're doing pretty well – and, as ecologists, we can't yet do that. In that sense Species Distribution Modelling encapsulates all of ecology. But, as we've discussed, the *current* models do not – because ecology is also fundamentally a science of interactions.

From the point of view of climate change, having appropriate Species Distribution Models would enable you to actually make predictions about what areas are important for future biodiversity: Living in the world where we live now, we need some sort of protected areas, but where would it be best to put those protected areas in order to conserve everything that we've got now; how can we develop a network of protected areas that can safeguard the future of that biodiversity?

If we caricature climate change as an increase in temperatures across the globe and consider that populations have limits as to where they can live defined by temperature, we would expect geographic range shifts in those populations. At the hot end of their range populations will become less successful as the temperature warms, and so they will reduce in number; but at the cold end of their limits populations will become more successful as the local temperatures move towards the organism's optimum temperature. As populations colonise locations that were previously uninhabitable, a geographic range shift can be induced by climate change.

Now, one of the properties of a range shift is that there will be lags in the rate at which locations become available and the rate at which populations colonise these areas. Things aren't in all places all of the time selecting where to live, they are born in places and might seek new places from there, with a limited ability to move. It is through these lags that the shape of a population through space is generated.

If you think about the shape of a drop of water on a flat surface, that's a bit like the shape of a population along a gradient. Now if you tilt that surface, the water droplet changes shape. It becomes more like a teardrop. That's a reasonable analogy for the change in the spatial structure of populations under climate change.

A recent piece of theoretical work I did[5] looked at how that change in structure affects evolution.

---

[5] G. J. McInerny, J. R. G. Turner, H. Y. Wong, J. M. J. Travis and T. G. Benton, 'How range shifts induced by climate change affect neutral evolution', *Proceedings of the Royal Society B.* doi: 10.1098/rspb.2008.1567.

What this highlights is that, as soon as you start thinking about climate change, you are actually thinking about a whole new, different but predictable, part of ecology and biology. The lags create a new quasi-equilibrium with the environment during climate change. This alters who is most successful in a population through space and in relation to the environmental conditions they experience. Because the individuals colonising new habitats contribute far more to the next generation, whilst those at the rear of a range shift are contributing less to the next generation than they would have done without climate change. This means that a genetic revolution in a population could happen far more quickly during a range shift induced by climate change. The suggestion is that genetic changes and evolution could happen more rapidly during climate change. This might be very important to our understanding of how biodiversity is maintained and generated. Whilst the great focus has been on the extinction of species that couldn't survive, because of the way this frees up resources for other species, these spatial processes have been overlooked.

So we have the genetic changes occurring in a population; but also, populations are exposed to environmental conditions – such as temperature – in a different way. This alters how natural selection will act within populations: Individuals may be exposed to 'novel' temperatures. It's a new area of ecology and evolution really.

C: So this could alter significantly the type of issues we think are involved with climate change, and their impact on biodiversity.

GM: It's certainly interesting from the point of view of how we manage biodiversity in the future, but it also makes you think about how those processes have generated the biodiversity we see today. These processes are a bit like a phase transition from one form of dynamics in stable climates to another form of dynamics in a changing climate. The suggestion is that the forces change populations more quickly during climate change, and it takes a while to 'relax' after a range shift. So we might be able to understand how species are packed together through space – what are their niches, why are they a certain size – through this better understanding of climate change responses.

C: So attacking the specific problems of climate change uncovers new insights into the general problem of species distribution, the very framework in which that problem is posed.

GM: Yes, this could give us some insights into why there are the number of species there are, rather than ten times more or ten times less. *Niche* is the key term, because if you could model the niche more appropriately than you could have better Species Distribution Models; but then people get scared of saying that they are doing niche modelling, because the niche is a nightmare!

C: How has the niche been understood in ecology generally; and in your work how do you *mathematically* define it – what kind of space does it exist in?

GM: It's difficult, because different people use the word 'niche' for vastly different things. It started out as a description of where a species is likely to be found – a correlative description. The simple explanation of the niche is the set of conditions in which a species can survive. For instance the ranges of temperature, light, water availability, pH, and so on. [G.E.] Hutchinson defined the niche as an *n*-dimensional hyper-volume.

C: With, in each dimension, limits of tolerance?

GM: Yes, within this hyper-volume, everything's going to have some sort of limited range where its births and deaths are equal, another range where births are more, and so on. So long as deaths aren't greater than births, then the species can survive.

It gets a little bit more complicated, because species might also *augment* the environmental variables, for instance light may be reduced by a tree. If you think about these variables being used as resources, you get a different formulation of the niche than if you think of variables as merely defining tolerance. Light is directional, so if I'm a tree in an area with my favourite light level I might thrive. But through my growth, anything below me in height gets less light. So I've engineered my environment a little bit – it doesn't just affect me, it affects everyone else. And my presence affects my offspring as well, if they can't get far enough away from me.

From the resources that come in, you've altered the niche and created something else. So if a second species is present, it might do better in that altered light environment if it prefers shade. Or it might do worse if it needs higher light levels than are possible with the presence of the tree.

C: If one species disappears from an environment, the niche 'landscapes' of other species change. Which is a crucial consideration in trying to predict species which are at risk of extinction.

GM: Totally. This is where facilitation and competition come into it. We generally conceptualise the niche in the absence of other species as the 'fundamental niche' and that in the presence of other species as the 'realised niche'. And another species may in fact be a specific *requirement* of the fundamental niche, as a resource. Another species can make the realised niche bigger than the fundamental niche, through facilitation.

Of course, the realised niche is what we are generally able to observe in the real world. But the realised niche is context-dependent – that is, it might depend on what combination of species are present. There are in principle an infinite number of realisations of the niche possible based on species interactions alone. There are many other factors that determine the realised niche, such as the spatial arrangement of a variable and so how populations interact through immigration and emigration.

C: Not to get too caught up in voluntaristic language, but could we say that any species 'tries' to expand its niche, to simplify the world according to what is important to its survival, so that the environment is a kind of 'interference pattern' of each species' monocultural 'ideal world' (a kind of organic niche-fundamentalism)? So the problems of biodiversity aren't limited to preservation – they also involve a consideration of how the evacuation of one niche will alter another, will allow another species to expand perhaps dangerously – in a 'cascade' effect.

GM: It is probably best to first consider why a species has a limited range in the first place – why it has a niche and why that niche is defined the way it is.

Everything has ranges, so there must be some trade-offs in the physiological engineering of life that means being good at something makes you less good at something else. Some species are more generalist than others, so there are differences between trade-offs at different points of a gradient, or different ways of doing that engineering that can overcome obstacles.

But there can also be barriers created by the structure of genes and their inter-relationships. Linkage between genes may mean that a change in one gene affects other genes, so evolution can be constrained if the other genes are affected negatively. This is an engineering problem as well. (Of course it is important to remember that this engineering is done in a passive way: Life doesn't see a problem and try to surmount it. It is done, beautifully, through natural selection.)

Then we can ask why niches are fairly stable and why they occur where they do in a space. For instance, if you think of a tree line on a mountain: Why hasn't the tree evolved to be a bit more tolerant of cold? Why don't things evolve a little bit more to be more 'successful'? Why can't species live at one degree more or one degree less than their

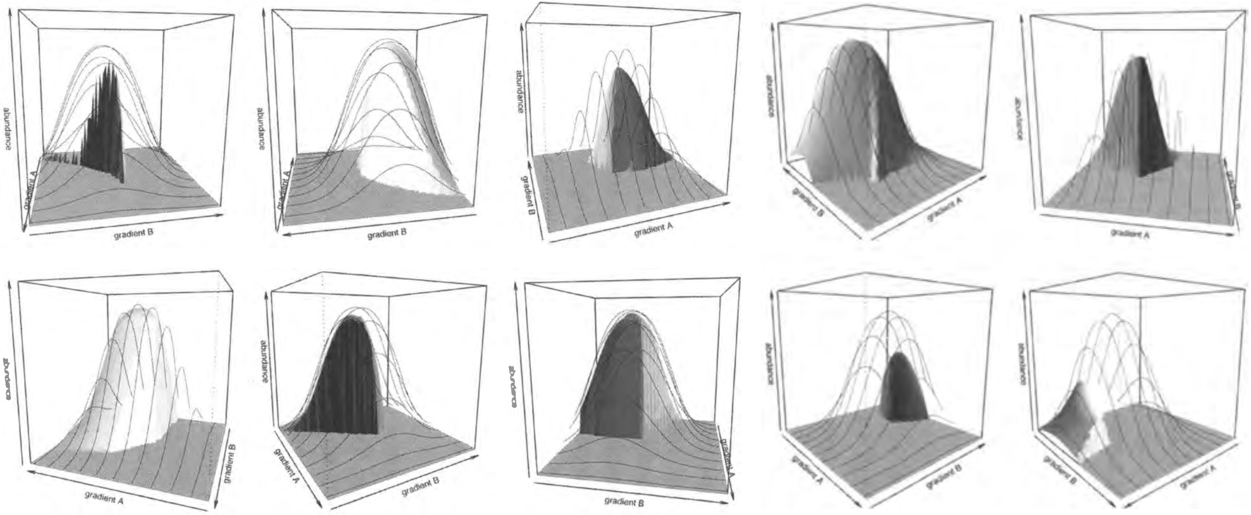

Fig 2: The effect of competition between species. These are the results of competition between a group of species in a computer simulation. There are two abstract environmental 'gradients'; e.g., gradient A = temperature and gradient B = rainfall. The species have restricted niches along these gradients (x and y axes). The black lines show the outline of the fundamental niche defined by the abundance of each species (the z axis). The grey surface shows the realised niche after competition between species has occurred. Species may not live everywhere they can because other species out-compete them. In the top left panel the species has been severely restricted by competition. Note that correlation between its realised niche and the gradients would tell us very little about where the species can actually live. The other species show varying levels of inequality between fundamental and realised niches, demonstrating that a 'correlative model' between the environmental conditions and abundance would give results erroneous to some degree depending on the species.

actual tolerance level is now? I see this as being one of the most interesting things that we don't actually know about – why aren't things more abundant, why don't they have wider distributions, what processes keep populations in check? Some of it is bound to be competition, but that's not all that is at work. Part of the answer must be in the physiological engineering. However some answers lie elsewhere and require an understanding of population dynamics and gene flow – an understanding of the system.

Sexual populations exchange genes during reproduction, so even if a new gene arose that could be more successful than everything that came before it, it could be swamped out of a population by all the rest of the genes that are floating around the gene pool. The probability of passing on a successful rare gene could be less than the probability of passing on a very common but potentially less successful gene. Genes have to *invade* a population. If a gene cannot invade because of the larger number of resident genes, this is called 'gene swamping'. The same thing can also happen across space, as immigration can swamp the gene pool with genes which were selected for in a different set of conditions. This is a really intriguing idea that is increasingly attracting interest.

A gene may also arise that the 'wrong' place in a population. For instance, the gene that gives greater success in a cold environment may have natural selection acting upon it in a warm environment, where that gene produces an unsuccessful individual. Also, the probability of that gene occurring will be linked to the variation in all genes within a population. At the edge of a population, where the gene could experience the conditions in which it would be selected for, population sizes may be low and so the genetic variation is also low. This means that the probability of even getting a more successful gene is small ... You can see that there is a lot to consider here!

So the removal of one species could directly affect the realised niche of one species through competition – their fundamental niches overlap and so the remaining species would directly occupy a larger realised niche. This could happen quickly. But if those fundamental niches don't overlap then there isn't going to be any certainty that the now-vacant niche is going to become occupied any time soon. It will rely on evolution occurring, and there are lots of barriers to that potential evolutionary trajectory.

C: What this seems to emphasise is that whilst we can understand how an *individual* of the species interacts biologically with its environment, and what its tolerances are, we don't yet fully understand the tolerances of *populations* – why in certain cases a population may not be able to tolerate an environment which you would expect it to.

GM: Yes – to put it in the perfect context, if you did an experiment where you put lots of individuals in lots of different temperatures on their own and studied which ones survived, that wouldn't tell you anything about whether a *population* would be able to sustain itself at that temperature or not. Similarly if you had lots of populations evolving at lots of temperatures but all isolated from each other – without gene flow – then that wouldn't mean that was the possible niche of a population that wasn't isolated and which was actually exchanging individuals.

Some populations could supplement other populations that could not survive otherwise, through immigration. These are three ways to consider a fundamental niche – individual context, population context and spatial population context.

Because we have great variety between species, trying to generate laws that describe the processes that determine the size of niches and the conservation of those niches is very difficult. There is a large amount of contingency in any answer you get, because of the variety of life and the variety of circumstances in which that life finds itself.

C: So in that sense, that theoretical breakthrough of population thinking which you were talking about has yet to unfold all of its consequences for the way we understand the biological world; and it has massive importance for understanding changing conditions on the planet.

GM: An appreciation of how biological dynamics are played out when we accept all sources of variation across scales is in all likelihood not achievable. But I think we will start at least to appreciate how different sources of biological variation interact. New sub-disciplines pop up all the time. Each sub-discipline – based on understanding and not necessarily method – acknowledges that a different combination of variation is important in describing the world. For instance molecular ecology, population genetics, eco-physiology ... But these in turn are *scientific* niches – there are limits to where *they* can expand due to the trade-offs in model building and the fundamental engineering of personality and capability in humans.

When you have so many things that could be important, where do you start to build a model? It may not be at an objective place. You will start from the small set of personal knowledge developed during your education and experience. What units people start with depends on that.

Classically, ecology was about individuals as units. But now we know that it matters how you make abstractions about the different ages and different sizes between individuals. So we have changed the units. And then, we know that different genetics respond in different ways, so we have different units again. Then, we know that history has an effect – so even if you were the same age and genetics, it matters what you parents did. For example, say I was born from a really fat, well-resourced mother, she might have had lots of spare energy that she could use to provision for my egg; she might have looked after me in a different way because she had this relative extra energy, This might affect my success in the end and how 'fat' I was when I became a mother myself. This might mean that I would provision for my eggs in a different way from someone of the same age with similar genetics. This can drive different population dynamics.

C: Do you build in these trans-generational dynamic traits in your models?

GM: No, this kind of detail is only known about a tiny minority of all species and populations of those species. In my PhD I did some experiments in this area.

All of this isn't yet taking into account the effects of other species, spatial dynamics within ecological communities, behavioural effects, genetic and evolutionary changes. There are so many ways to conceive a set of dynamics and the units of study, it is interesting to wonder how development of the details in these different sub-disciplines affects the prospect of a more holistic understanding. There are fundamental differences between the way our flagship ecological systems have been measured and studied, producing different messages for our science.

C: With these extremely complex problems you've been discussing, how in practice do you work towards an experimental outcome that's going to be useful towards addressing a particular problem? Or are you more interested in contributing to the general understanding?

GM: I think I used to be much more interested in contributing to a general understanding, and always used to feel a bit more comfortable when people would call it 'blue skies thinking' and to see that they attribute value to that; but I've now begun to feel a bit more confident that the general understanding should and could be formalised in a way that's a useful contribution.

Whilst we can stroke our beards over a cup of chamomile tea and wonder about the complexity of it all, there are some very straightforward things that would be immensely important contributions. Species Distribution Modelling is one instance: If we can do that better, we may be able to make better predictions for adaptive management in relation to climate change and habitat destruction. But also, we will have made a better job of quantifying the fundamental unit of the sciences of biogeography and macro-ecology. This would enable a whole set of new questions and understanding.

I think better Species Distribution Models could be an achievable and significant contribution.

Where I am now is much more about wanting to make a contribution that has potential practical application quite quickly, but I think what you find is that making something useful always implies making a contribution to the scientific understanding, so the two things aren't exclusive. I think it's a frequent mistake in the conservation world that people say, "we care about it, we are doing this", but if it isn't based on some kind of understanding of the system, you are merely doing what you *feel* is good … in a lot of other things that's probably the right way to go, but not in science!

C: And do you feel that we are capable of bringing about that understanding in time to do anything about climate change?

GM: One constraint is obviously financial support, which is a political and social constraint. Even if we knew and could model all these things and could provide great advice, we'd still face the total nightmare of the inertia of human action.

On the other hand, one of the key *scientific* constraints is poor data: For instance with Species Distribution Modelling, the data is usually quite poor resolution – you can't see abundance clearly, you've just got sightings marked down on maps, grids, so then you are kind of working with the conventions of cartography that people chose to use, for entirely other reasons – ten kilometre by ten kilometre squares, or whatever. A lot of data we will end up using has not been collected with the express purpose of Species

Distribution Modelling in mind, or at least the specific kind of modelling that we are doing; and also there's just not enough data about distributions. We don't have data on every species, we don't even know every species that exists. We are working within constraints that are really skewed by the way humans have previously acted and the way in which generally they make decisions. These actions and decisions have shaped the exploration of the world, and to some degree, how we will be able to explore the world in the future.

C: This adds another dimension to the fact of working with a scientific legacy that determines how you abstract the empirical data: You are also working with a 'data legacy' that lags behind the kind of processing you would like to do with that information, and the resolution that processing demands. Each generation of ecologists works with the data of a previous generation, gathered according to other presuppositions as to what's important …

GM: That's a really interesting thing about science. It's kind of a modern thing since the 1950s to actually rely on statistics, and before that, good statistics didn't really exist. A lot of scientific knowledge could be based on very different statistics than we use now.

People use very complex routines now; we know that in the seventies they might not have done, but we still use their findings. So our knowledge is contingent on whether they were right or not. When a new statistical method comes out or is popularised we don't go over every past experiment and see if that changes things!

Then there are various fads as to what people study – so, in ecology, people love to study mammals, birds, and butterflies and suchlike. Then your understanding of ecology comes from those taxa, an understanding based on human interest for a small part of biodiversity. The revolution in microbiology is fascinating from that standpoint – we get to see how ecology transfers to a significantly different type of organism in quite some detail. It already puts into question how we conceive species as a unit of study.

I guess when the first biologist went out they were just like, "Cool new species, cool new species," and that was what drove them. Finding a new Orchid would have been far more exciting than a new moss. Nowadays, people are probably getting more pragmatic because of the environmental problems that society faces, and when they collect data, they realise that it has wider consequences. If everyone in the world had a good knowledge of what the organisms are that live in their proximity, and every time they walked to work they wrote down something and shared it, then we might have a lot less trouble with data!

C: So then everyone would be a spy for you!

GM: But people used to know so much more about their local environments in the past – I'm sure if you asked a hunter-gatherer what's in his area and where it is he'd have been able to tell you. People depended on that knowledge. But there's a disconnect between nature and modern life, so then it is a scientific enterprise – ideally being some kind of data forager rather than people who navigate the wild!

It is a serious point though, and there is great interest in 'citizen science' as a means to collect data and reconnect people with nature. The greatest hurdle is to engage those who are entirely disengaged: The more socially deprived aren't going to be as likely to carry around iPhones for which they could download applications that allow them to recognise leaf patterns or upload photographs of plants with location data. It isn't going to happen. We need to think about science education mediated through large-scale science. Collecting data on a tree can be part of a lesson about ecology and how trees work. But that data can actually support the harder research end of the science and so get people involved with science at multiple levels. Computation is inevitably the link between the data-gatherer and the application of science. It obviously needs more research into how it could work!

C: You said before that many people involved in climate 'activism' seem to be doing what makes them feel good, with little regard to understanding the reality of what's going on; and a part of that emotional commitment is the idea that if we just 'let it be', things would be okay. But the very idea that we could 'let nature be' just seems to be a complete fallacy. Human beings, like every other species, have never just let nature be – we are part of nature in the sense that our technologically-augmented niche overhangs and affects the niches of all these other creatures. So what's the position of the human in all of this, once the data is 'in'? Is it non-intervention or intervention that's important? Is it going to be the case that we need to intervene in order to actively engineer population distribution?

GM: From the point of view of letting things be, that isn't really an option. Our (human) influence is global, so even areas that are very far away from direct human activity are going to be affected by climate changes. The option of having nature reserves where biodiversity occurs now is maybe past. But at the very least we should aim for is protecting those places.

It would be great to think that we could reduce our human niche's influence and have the choice of letting things be. Humans are a nightmare for everything else. Our niche is tapped into a vast set of resources, we use resources that most life couldn't even contemplate, such as oil. Humans have developed an immense niche that had never existed before and that no other species had experienced in their evolutionary history. And just to note, that's an important thing about niches – they don't exist until something makes them exist because that thing exists. There wasn't a niche for dinosaurs until the dinosaurs actually made it.

C: And as a creature evolves its niche evolves along with it.

GM: Yes, because a creature defines its niche. There is a common misunderstanding here: Say I killed off the primrose – totally wiped it out – that doesn't mean that 'its' niche would be available for something else to come along and 'evolve into'. It just means that the resources it was using are available and the primrose isn't using them or affecting other species that lived around it. The niche is a description of the primrose. Something else can use those resources in a different way and that something else may require a different description for its niche. If something else evolved that used all of those resources that are now available, it doesn't mean that it would become another primrose.

So, when humans came along they didn't fill some niche that was there before. Niches aren't necessarily always in existence, although there may be a similarity in the niches between species. The niches of different species are different. That is part of why they are species.

The niche of humans has evolved into something incredibly novel and complex. It affects so many other things through its by-products and through the direct action of humans. From fishing and habitat destruction to pollution and eutrophication, to the creation of novel habitats and the movement of species around the world, we have quite an influence on biodiversity.

Another thing I should bring up is density dependence. As a population gets bigger, it can't go on growing forever. As populations get bigger and bigger there's going to be some constraint on resources that will develop and alter growth and survival of individuals; or maybe diseases and parasites become more easily passed between individuals when a population is dense and so diseases can become more prevalent at higher population densities.

At some stage a population will encounter population regulation, through density dependence, so the numbers of births and deaths will start evening out and that population will achieve an equilibrium of sorts. The entities you will compete against are most likely to be things that are very similar to yourself – organisms which require the same resources as you. This is more likely to be your brothers and sisters and the rest of your species. Populations have to be regulated in our finite world – you can't just go on and on.

But humankind aims to work in a density-*independent* way: technological innovation allows us to exploit resources in a new way and become more efficient in exploiting them. Or technology allows new resources to be exploited. This allows new population growth and new lifestyles. Our lifestyles are probably incredibly different when an innovation is first employed, compared to the later part of an innovation's history, when the population size that innovation supports has increased and approaches equilibrium. As we approach equilibrium there would be a different sharing of the resources that technology yields.

C: Are you saying that no matter how much we've augmented our niche, it still retains the tendency to return to a natural equilibrium?

GM: In some sense it should do, but equilibrium is a tricky concept!

However if we as a society understood density dependence a bit better, and (in some weird parallel universe) if we were actually willing to act upon it and manage ourselves based on that understanding, then we would probably be doing better. But we don't, and each innovation changes the rules of the game.

Technology also changes how the population would actually be regulated: Say you had two populations that had exactly the same amount of agricultural fields as each other and those fields were of the same quality, but one population had 'normal' crops and the other one had GM crops which produced more food. Then the GM crops would probably be able to sustain a larger population for the same unit area. In that kind of way, technology separates and changes the rules of the game of nature. Having more people means you produce more waste, you are also putting more pressure on the land and other resources such as water. That population is regulated very differently.

Once you up the stakes and develop technology that's better at acquiring resources, you will change where density-dependence kicks in. In effect, technology keeps on changing the nature of the actual processes that define the human's niche.

In our hypothetical case of populations with GM crops, a population may be now constrained by water, or by their higher population density engendering conflict. Whilst in the populations with normal crops, they will be regulated by the actual productivity of the crops, because no other resource is being pushed to its limit.

In some ways humans have had an amazing run of it really: Each time natural constraints bring the population to equilibrium or breaking-point, actually to the point where regulation takes hold, further innovations have been made – necessity is the mother of invention – so technology has augmented the niche further. Presently we humans have taken this so far that everything we do affects the rest of the world and other species, and we are pushing its limits as a sustainable, self regulating system.

I don't usually engage in these kind of dialogues much though, and some of these arguments are a crude driver of anti-capitalist politics, which I'm not a part of. But if you treat the dialogue properly then there are some suggestions that the ecology of everything can inform a reasonable kind of capitalism and usage of the earth.

C: 'Reasonable capitalism' – a contradiction in terms? Is it possible for us to moderate that tendency to create new problems and new solutions that create new problems?

GM: To me it seems that in some way the human race thrives upon and celebrates itself for this activity. We love the history of our own development and labelling societies with technological descriptions. In some ways it is an enjoyable part of the ride of being human. It's that interest in problem-solving. It would be quite an innovation that could quell problem innovations! We are on a super innovation snowball, especially with the 'birth' of modern biology. We are innovating technologies to tackle problems generated by our previous innovations. It doesn't seem like we are in balance does it?

C: If we make this assumption that the augmented human niche has this massive effect on all these other niches, and that this is not suddenly going to stop, then we have to confront the difficult questions of biodiversity: Are all species sacred qua life-forms, so that they must be kept alive; is it that we are looking to keep the species we know to be important for *our* survival; or is it that we need to understand all the interactions between them so can know which ones we can let go and which ones not? What *is* the question of biodiversity?

GM: Everyone will tell you something different. It is an incredibly hard question and depends on how you define biodiversity and how you value biodiversity. My own personal take on it is that the population is no good if it can't reproduce enough to sustain itself.

C: Even if it's the fault of humans? … was the Dodo's population 'no good'?!

GM: What I really mean is that the point of populations is that they produce new generations. That's nature's take on it as well. If you don't, you don't survive.

How far are we willing to take the conservation and management of biodiversity if we produce a world in which a natural population can't maintain itself? That is, how far are we willing to change the earth and create the situation where there are value judgements to be made?

Making value judgements on species is an interesting exercise, but the point is that we shouldn't be addressing the symptoms. It is a deeper-level change in global society that is needed, then we wouldn't need to think about those judgments as much! There are root causes, and conservation doesn't always tackle them appropriately. It is beyond the conservation remit.

And in a similar way, biodiversity needs to be in a good condition itself – it needs enough components of biodiversity for it to maintain itself. From a few billion years ago until now, biodiversity has been pretty good at breeding more biodiversity. Despite an immense meteor strike that killed off vast quantities of species, we have still ended up with a lot of biological variation. What happens if we change all that? What if we reduce the system that produces biodiversity too much?

I think things do have a sacred intrinsic value, that they are totally amazing phenomena of the universe, which we should be custodians of; but then it's intensely difficult to know how to actually do it when our own human population grows, spews and expands. I think the most operational thing we can do is to assign value, then you can relate it to policy and then it becomes something functional. The level of our effects will have to equilibrate with the levels that biodiversity can withstand.

C: You mean that, whatever our feelings about preserving the great spectacle of life on earth, in pragmatic terms – convincing government leaders to take action, and so on – we have to take on this task of assigning differential value to lifeforms. Once again, the question is whether ultimately we do so in terms of their value to the thriving of humans?

GM: I think the 'sacred nature' line is useless in a pragmatic situation. Of course, I get a spiritual benefit, if you want to put it in those terms. But if you can quantify a harder value for things it makes it a lot easier, rather than setting rules that rely on people's respect for sacred things, rules which people aren't very good at observing. I can't see the earth being 'managed' well unless it is hardwired into society that activities that exploit the earth badly are of less value than those that exploit wisely. Humans respond to hard currency.

These days people have to make decisions like, we've got *x* amount of resources so what are we really going to save. It sounds harsh to say that it's a mistake, but with the panda, for instance, it's become this feeble mammal that can't manage for itself apart from in this weird old people's home for species, where it's nursed and they help it reproduce. They do some phenomenally ridiculous things to help it reproduce, like the males produce better quality ejaculate by having a degree of anal stimulation. So they do it! And then you are 'saving the species'! At that point, it all becomes quite comical. Is that a good population? Do we want that principle to be our flagship of conservation?

C: And why this particular species? Because it's cute! We wouldn't put that much effort into saving a tapeworm.

GM: Yeah, completely. [Laughs] We should be thinking about what components of diversity we want to save and the ability of those species to save themselves. We only have limited resources for conservation and we need to do a good job of developing an education that produces a society that understands nature and its management. Not saying, 'we're saving this weird bear thing in China that can't do anything for itself, but look at its cute face …'

C: It's somewhat contradictory anyway, because there's no link to biodiversity there if the species has already been removed from its environment and is being kept alive in an artificially-augmented technological environment that is really an outgrowth of the human niche. It's already extinct as far as the biosphere is concerned, isn't it?

GM: That's a really good way of putting it. If you start drawing lines around everything in the form of nature reserves, then you make certain populations extinct *to other populations*. The interactions across space are hugely important.

It all comes down to a bit of gardening. That's a bit of a caricature maybe, but if during climate change organisms can't actually reach the places that would permit their persistence, then you have to kind of pick and choose who you want to survive: Do you do assisted migration, where you would take things to new areas? This is potentially very large-scale gardening. What's natural about it?

C: From the point of view of nature being intrinsically worthy, and its having to be treated with respect and saved, the criticism against your work – quantification and computation – would be that you are merely participating in the technological manipulation and management of the world. Therefore ecology just becomes an extension of human's despoiling of nature. Is that necessarily where your work is going to lead – more manipulation?

GM: I don't necessarily agree. You can see what has resulted *without* the science: Precisely the uniform despoiling of nature. It's better to think about it as the technological manipulation and management of the choices humans make. It's providing the information for choices, and ecology's suggestions are always bound to lie on the less destructive side of what would otherwise happen without ecology.

We don't really have the luxury of doing manipulations for the sake of understanding at the largest scales. We are living in the one biodiversity experiment we know of. We can't really manipulate the system to find out what will happen, and then inform ourselves that it wasn't a good idea. We have one set of experimental material and we don't want to do an experiment that loses all that experimental material. There is one Earth, one instance of an experiment – no repetition possible, no replications. So you are set apart from your system differently than in other areas of science. This means you have different ethics about it.

People can find a way of abusing the information that they find out, but if we can act on that information and monitor the situation then we can become better managers. Again, can people be trusted to let things be?

C: But, again, what would be the ultimate outcome in terms of policy change or actual action in the environment of what you are doing? Will it take the form of further manipulation of the environment?

GM: The worst thing that could happen if we had a perfect model is that we could just give a really good description of when everything is going to die off. And that in itself would just end up being some sort of political tool.

You can step back at this stage and say, "Can we do some sort of management associated with those models?" But it becomes quite tricky because are you assisting in migrations, are you moving things around, you are deciding, "no, the bears are far too abundant in our model at the moment so there should be ten less this year." Do we start killing stuff off?

C: Exactly, because the one rigid ecological law of life on Earth is that there are limited resources, so if you are talking about that kind of manipulation then one population has to be thinned down for another population to get to a size where it is going to be viable for the next generation.

GM: And that will always come back to some sort of value judgement. I'm interested in assisted migration, and the fact that it has evolutionary consequences. You might take away some kind of bird and populate Scotland with it because you think the climate there is going to become more and more to its liking, and the population isn't going to get there by itself. But then you have essentially created an invasion. There were a whole set of reasons why that environment didn't have them in the first place, and so all the other species which are there weren't exposed to that species. Most experiments of that kind show that it actually has a negative effect. About two years ago everyone thought it was a great idea and now everyone's come back to a more cautionary principle in the literature: "We don't know what's going to happen so we can't do it." So you are caught between the best of our ecological knowledge – well, a certain portion of our ecological knowledge – that might say that assisted migration is the best thing to do, and the fact that we just don't know.

C: This seems to echo the basic problem, where environmental action is caught in the same potential technological positive-feedback loop of capitalism that we discussed earlier. We know humans have intervened in harmful ways, but the only way we can do anything about it is by intervening more. And that presents the risk of creating even more problems.

GM: Totally. People got quite into the idea of 'wilding', making areas wild, so for a lot of situations you can see that that's a good thing, but then people will also say we want wilding but we want to return it to a pre-human natural state.

So then they're saying we want a wild area, in a wild state, through human management. Are these areas really big enough for the large wild mammals they might have supported?

C: And again, it's essentially the concept of the reserve – a walled-off space.

GM: And people don't necessarily want to live alongside biodiversity. I would say that biodiversity isn't appreciated enough really. It's only when it's too late. People don't appreciate its importance until they exactly know its value. Like all the fuss over the declines in pollinators – the declines in bees, and flies, and whatnot – is only put in context once they realise that *x* million pounds of crops aren't going to be fertilised and produce the grain. Then the pollinators' services have value and their decline becomes a 'problem' to society.

C: Again the same paradox: The earth has to become entirely capitalised and technicised in order that it become desirable to preserve it as 'natural'.

GM: We are going to end up with a world where the most 'natural' of populations are found in the most inhospitable places. I daresay the inhabitants of deep-sea vents are probably going to be fine for quite some time. Well, until people start tapping that energy source and so destroying those habitats.

To be honest, conservation is slightly removed from what I do, generally. I am an ecologist but I have my opinions. Saving the planet is a big job and it isn't going to be solved solely by the science. It's not like I'm actually here to save the planet!

C: We didn't mean to imply that it was your responsibility to save the world ...!

GM: I know, but a lot of my friends and family assume that is what I do and why I do it. The word 'ecology' is used in many ways and people are frequently more likely to associate it with recycling plastic bottles and providing compost heaps than they are to associate ecology with the science. People expect me to be a tree hugger, and wear tie-dye.

What you have been saying ultimately points to two (caricatured) options: You could maintain the Earth as some sacred place – get on spaceships, go somewhere else. We could take some species and samples, creating synthetic natural communities which provide resources and can support our lives, but lives not on Earth. Then everyone sits on their new planets and looks back at the earth thinking, "that's very natural, you know".

Or, as looks most likely, humans can be part of nature, understand it, and be managers rather than custodians. Human influence on the Earth has already had its effects. So either we leave now and manage nature on our space colonies. Or we stay and manage nature on our Earth. I think we are in the position that we don't have any choice.

RICH WILLIAMS (HEAD OF THE COMPUTATIONAL ECOLOGY AND ENVIRONMENTAL SCIENCE GROUP)

COLLAPSE: In the discourse on the environment and climate change, we often hear invoked the complexity, interconnectedness and diversity of the 'web of life'; but your work seeks to determine quantitatively the degree to which these factors affect the sensitivity or robustness of species considered in their interrelation with others. Thus we would be able to understand how the depletion or extinction of one species might have further ramifications or lead to 'extinction crises'.

Aside from the difficulties involved in decision-making and the triage involved with 'promoting biodiversity' – Can we even define biodiversity (and the related terms 'stability', 'richness') in a way that is not determined by human interests?

RICH WILLIAMS: I think we probably can. I don't think the traditional species definition is particularly oriented towards human interests, so a measure of biodiversity that is simply a count of the number of species isn't particularly 'about' human interests. I don't think the issue is whether defining biodiversity involves human interests or not, but whether constructing an argument for conserving or protecting biodiversity involves human interests.

C: Okay, so does the *promotion* of biodiversity merely index value for humans, or is it to be regarded as something valuable in itself – so that a more biodiverse area should attract investment regardless of how its thriving affects us?

RW: Firstly, to question the question, why use the word 'merely'? And what does 'valuable in itself' mean? Isn't valuable always qualified (even if not explicitly) with 'to whom or what'?

Biodiversity is an interesting concept to me. Consider the species richness, for example, in a tropical rainforest as compared to a temperate deciduous forest: The tropical forest is far more biodiverse. If you decide that species richness is a useful measure of biodiversity and that biodiversity is important to conserve, this points towards deciding that it is more important to conserve the tropical forest than the temperate one. I don't want to be the one making that argument!

The history of biodiversity as an idea needs to be looked at closely. It entered the literature and the public discourse quite recently – during the 1980s – and while always defined more broadly, has tended to focus on the existence of species. It seems to have been a concept put forward to argue for habitat conservation because it is easy to grasp and has strong emotional appeal. Ever since its introduction, scientists have been trying to rigorously define the term and develop a strong scientific justification for its conservation.

C: Interesting that it should exist as a 'marketing term' in advance of its scientific definition …

RW: I wouldn't say that the term preceded its scientific definition, more that it preceded a clear scientific argument for the importance of its preservation. (This is not to say that there are not very good non-scientific arguments that have been made). In ecology, the debate has shifted over time, from a concern with the role of biodiversity in the stability and robustness of ecosystems to a more recent framework that tries to link biodiversity with ecosystem function and argues that we need to preserve the function of ecosystems, which in turn justifies preserving biodiversity. Even more recently, particularly in the policy arena, biodiversity is linked, through ecosystem functioning, to ecosystem services, an attempt to define the goods or services that societies gain from ecosystems, thereby connecting the science to economics.

You can see the difficulties by returning to my earlier example and asking: Does a unit of area of tropical rainforest provide more or less ecosystem services than the same area of temperate deciduous forest? This is obviously a very difficult question to try to answer, and one that is likely to depend heavily on the perspective of the person trying to answer the question. But I think we can put aside a lot of these difficult and value-laden questions and realize that we – individuals and societies – are dependent on other living things for a wide range of both physically necessary and psychologically desirable things and that we are all active participants in ecosystems. It is also clear that human activities around the planet have drastically altered ecosystems, particularly in the last century as the number of people has expanded so rapidly and technology has greatly increased our ability to affect natural systems, and these alterations have often had negative effects on human well-being or are stop-gap measures that are not sustainable. Finally, our understanding of the ecosystems we all depend on is limited, as is our understanding of the ecological consequences of our actions. Putting all of this together, it seems sensible to develop a deeper understanding of how ecosystems function so that our interactions within them can be better informed. I don't think you need to be a conservationist to think that it is sensible to want to better understand, predict and perhaps eventually manage ecosystems.

C: Admitting, then, that it should be the focus of this search for a deeper understanding, it seems that up until recently, this complex interconnectedness, although acknowledged, has been bracketed as being topologically intractable. But you suggest that we may be able to discover a 'simplicity on the other side of complexity' (in the words of Oliver Wendell Holmes which serve as an epigram for one of your recent papers).[6] Specifically, you argue that the catastrophic 'web collapse' that may result from one species' extinction may be amenable to prediction.

Could you tell us a little about the fundamental theoretical model you are using here – that is, what kind of 'ethological ontology' are you working with?

RW: When I or most other people look at the natural world, we see a large number of separate interacting organisms. This is probably one of the most basic simplifying abstractions most humans apply to the world. It is, however, just that – a human-created simplifying abstraction – and like all such abstractions, it persists because of its utility, not its truth. To further organize the natural world, scientists have grouped individual organisms together in various ways. One of the more common ways of grouping organisms, and the one we use in our models, is to group organisms into species, isolated breeding groups. With this assumption, we collapse any notion of space. Instead of a lot of individual organisms living on a landscape, we average across the landscape to get a much smaller number of species with abundances.

---

[6] E. L. Berlow, J. A. Dunne, N. D. Martinez, P. B. Stark, R. J. Williams and U. Brose, 'Simple prediction of interaction strengths in complex food webs', *Proceedings of the National Academy of Sciences*, 106:1 (January 6, 2009), 187-91.

The network is another basic abstraction we use – we look at how different species interact and construct a network of interactions. There are many ways in which species interact, and we choose to consider only one, one that we believe to be quite fundamental to the functioning of ecosystems. Looking at ecosystems as thermodynamic systems, we track energy flow – its capture by plants, its dissipation in all living organisms through metabolic processes and its transfer from one organism to another, in our case abstracted to its transfer from one species to another, through the consumption of one organism by another. In summary, it is an energetic null model, one that supposes that energy availability and energy transfer are the processes constraining the functioning of the system.

C: What justification is there for this contention that the idea of individual organisms is just a pragmatic fiction or a simplifying abstraction? This has obviously been a topic of hot debate in evolutionary theory, and begs the question, fundamental to biology since the collapse of the Aristotelian taxonomical model, of the independent existence (beyond our convenient categorizations) of biological entities. One can easily accept that models that have their origin in our own evolutionary utility have 'leaked' into the concepts of science; however are you suggesting that there could be ways to finally surmount this obstacle – for example, as you suggest, by abstracting over space and using a stochastic model – and that we thereby get closer to the real 'essence' of what is life on earth is (an essence which most people would find hard to accept)? Or is it simply an alternative abstraction which highlights different properties?

RW: Are you an individual organism? I think it depends on the question you're trying to answer. For some questions, you're best viewed as a member of a population, for other questions you're an individual organism, for others you're a community of organisms (there are after all far more bacterial cells on and in you than there are cells in your body, and so on). I'm much too pragmatic to be going after the 'real essence of life on earth' – I don't think I know what that means. Any scientific model involves abstractions – we need to find both abstractions and a model using those abstractions that gives useful predictions of the much more complex underlying system for particular questions, which usually means for phenomena occurring in a constrained range of temporal and spatial scales.

C: Your preliminary hypothesis 'that most aspects of structural integrity in the face of species loss of webs with niche structure generally increases with [species richness]'[7] seems to confirm the widely-held but vague sense of interconnectedness we mentioned earlier. What additional force does the computational model lend to this intuition?

---

[7] J. A. Dunne and R. J. Williams, 'Cascading extinctions and community collapse in model food webs', *Philosophical Transactions of the Royal Society B*. doi: 10.1098/rstb.2008.0219

RW: Decades ago, some highly influential work in mathematical ecology challenged the widely-held idea that increased diversity generally led to some kind of increased stability or robustness. Rather than being a general result, our new results are in part a consequence of constraints on the system's topology and the thermodynamic constraint imposed by larger organisms consuming smaller ones. The idea that complex ecosystems develop robust regularities in their behaviour as a consequence of their complexity is in fact borne out by these models, which are constrained to have ecologically plausible structure. These results give me hope that a more general theory and increased predictability of responses is possible. Like complexity theorists, I think about the possibility of a kind of statistical mechanics of complex systems composed of many interacting entities, a theory where the details of the complex behaviour of each entity are blurred by the abundance and multiplicity of their interactions, and this in turn leads to the occurrence of predictable system-level behaviours.

C: You are discussing models taken from statistical or stochastic physics and thermodynamics; does your work always 'borrow' models from elsewhere?

RW: I wouldn't say I always take models from elsewhere, but when useful ideas have been developed elsewhere, I look to them rather than trying to reinvent the wheel. Even with the simplification of aggregating individuals into species or other functional groups, the interaction networks, commonly referred to as 'food webs', are quite complex. Despite the apparent complexity, modelling and analysis of the empirical data has revealed regularities in the structure of empirically-observed food webs. One of the important regularities is that feeding relationships are lumped into quite constrained niches. The original writing on niches conceived of an *n*-dimensional space, where a species' niche occupied an *n*-dimensional hypervolume of that space (here I'm using an idea from ecology …). There's lots more to the niche idea, but in the spirit of simplicity, my and other's work on food webs has shown, quite remarkably, that these complex networks can often approximately be collapsed onto a single dimension, a line, with a diet niche being a finite section of the niche line.

A large fraction of the connections in many of the observed food webs can be predicted with a model that assumes that all species lie on a single axis, each species' diet being a nearly-contiguous interval on that axis; species tending to fall below their consumer's position on the axis. This then opens up the question as to what that axis means, whether it is correlated with ecological or evolutionary traits of the organisms. In many systems, the leading candidate for a trait which explains the ordering of the species is body size – simply stated, organisms tend to eat things from a constrained range of sizes, and those things tend to be smaller than the consumer. It is surprising to many ecologists that diet choices could be explained so simply, and of course it is not always that simple. Some of the success of these simple models of food web structure could be due to limitations in the data. For example, the available data sets typically don't include parasites, and when parasites are included, the one-dimensional models don't work very well – but at least in a few cases I've looked at recently, adding a second dimension greatly improves the performance of the model (which then of course raises the question of what is the biological meaning of that second dimension). But even with this, it is remarkable that much of the structure of many food webs can be explained so easily.

C: What shortcomings in previous models are you seeking to correct?

RW: Previous models of multi-species interactions have typically exhibited one of two drastic simplifications: If the behaviour of the species was at all complex, the network the species interacted on was drastically simple, often consisting of a two or three species food chain; If the model contained a large number of interacting species, their behaviour was drastically simplified and the topology of the multi-species network was usually also highly unrealistic. Our models have some greater level of ecological realism in the way species are allowed to interact (though they still leave out many potentially important biological processes); the models also contain more species, though certainly not as many as in most ecosystems, and the interaction network topology is generated by a model that captures many, though certainly not all, features seen in empirical networks.

C: How would these shortcomings of previous models have affected our current view as to the dynamics of anthropogenic species loss and climate change?

RW: The ecology included in climate change models is very simple – we are just beginning to develop models with somewhat realistic numbers of tree species in the forests. Explicit representation of animals, so obviously vital to many processes in plant communities – controlling seed dispersal, browsing and consuming seeds and so limiting establishment of new plants and growth of both juveniles and adults, diseases and pests affecting mortality rates to name a few important processes – is entirely absent.

Similarly, our ability to model the ecosystem effects of anthropogenic disturbances is very limited. There are well-established empirically-derived species area rules, so that if you chop a chunk of habitat in half, we can estimate what fraction of species is likely to die out. Predicting *which* species will die out is another matter. Another common human disturbance, the introduction of species from one ecosystem to another as our high mobility leads us to unintentionally homogenize life on the planet, leads to the problem of predicting whether a species will be invasive. Again the science cannot usefully predict invasiveness.

This is a long way of saying that ecology is a young science, dealing with enormously complex problems and systems. We are developing the science that in the future will lead to better-informed answers to these pressing policy questions, but I think that an honest assessment of the science is that reliable predictions of many important policy-relevant questions are still far away.

C: What is the wise path in terms of policy now, while this work is pending, if there is a gap between the perceived urgency of the problem and the youth of ecology as a science?

RW: I don't know what the wise path is, though like many other I have my opinions. One thing I do see going on is that while some people feel that this is an urgent problem, the resources put into the science are actually quite small. Perhaps this is because the problem is often so disconnected from individuals' lives, given that it is distributed across the globe and occurring on relatively long time scales. Some amount of caution in activities which have large effects on the natural environment would seem wise, but history doesn't offer much hope of wise decisions being made.

C: And what could the consequences of your own work be for our understanding of these issues and the future direction of research?

RW: My work develops basic theory about complex ecological networks. I hope this theory will one day lead to better decision making, but recognize that this is probably fairly far off. I see much ecological decision-making today as being done with a triage mentality: A severe problem is addressed with the best current knowledge, but the underlying science is often quite weak, extrapolated from a small body of empirical data with little underpinning general theory. Despite the urgency of many ecological problems, I think taking a more long-range approach to the science is an important contribution. I hope that by working to develop more general theory, the science will in the future be able to provide more robust advice when presented with the latest crisis, and perhaps also be convincing enough to allow policies to be put in place so we aren't constantly lurching from crisis to crisis.

That said, there is a very long way to go – the models we're using are certainly more sophisticated than past models but still contain huge numbers of simplifications and approximations. This is not a bad thing – scientific understanding comes from simplifying and approximating, from distilling the essential processes that capture a large fraction of a system's behaviour. The problem is that, unlike models of physical systems, ecological models are not constructed by simplifying and approximating an exact model. Instead, they are built by making an assumption about what processes the scientist thinks are important, building a model that captures those processes and then seeing how that model behaves. Then typically more pieces are added to try and make the model capture more of perceived biological reality and therefore perform better. There is typically a lack of a rigorous sensitivity analysis of the model, either to alterations in its constituent components or to the addition of other components. If it all sounds rather ad hoc, that's because it is.

Steps are being taken to build a more general theory and to understand the basic constraints imposed on ecosystems by thermodynamics (energy flow and non-equilibrium entropy dynamics), stoichiometry (nutrient dynamics) and information theory (genetics and evolution). There's a lot to do, no shortage of things to think about!

C: Can ecology ever aspire to the status of a mathematical science, or is the gap between the low-level (genetics) and high-level (ecosystems) too prohibitive?

RW: I don't think anyone would argue that the goal is for the biological sciences to be mathematical sciences. Like any science, the goal is to better understand the processes occurring and develop models to better predict the behaviour of the system. Ecology has been compartmentalized, with behavioural, population, community and ecosystem ecology being the main, quite separate subdisciplines. As the science develops, I think it will be re-integrated, so that we will better understand how the behaviours exhibited by individual organisms affect the overall functioning of the ecosystem. Behaviours of course have a strong genetic component, and so it seems inevitable that integrating across scales and connecting traditionally separate ideas, from DNA to ecosystems, is going to be part of a predictive ecological science of the future.

C: How is it possible to evaluate mathematical models' adequacy to a complex biological reality? This seems to be an important issue with such predictions: Not only for the general public, who in order to remain in denial often like to invoke the radical uncertainty and underdetermination of scientific models; but also at the level of governmental agencies who are called to act upon models which, as you have readily admitted, involve a choice of 'simplifications', and whose experimental confirmation is impossible or (at least!) unethical. There seems no apparent way to close this gap so as to deny governmental agencies any 'get-out clause' and ensure action. What is your experience of this phenomena of 'cognitive dissonance' and how do scientists such as yourselves think about and deal with the margin of uncertainty involved in these matters?

RW: A thorny issue indeed! On a technical level, there has been an awareness of the need to have tools for dealing with uncertainty, whether stochastic or intrinsic to the system's dynamics, for a long time. Dealing with the huge mismatch between the kinds of answers the science currently provides and the kinds of answers policy-makers and the general public want is much more tricky. Even today, the way that uncertainty in climate change models is dealt with in the public debate is incredibly primitive. In ecology and biodiversity science, we are decades behind climate change science in the kinds of predictions of system response to anthropogenic disturbance we can provide, and so the uncertainties are correspondingly larger. (This with the disclaimer that uncertainties in modelling the biosphere drive a huge amount of the uncertainty in the current Earth system models, but this is in the realm of unknown uncertainty in those models). With such uncertainty an inevitable part of the science for the foreseeable future, the science will be able to provide guidance and suggest future scenarios but ultimately decision-making must be based on more than science.

The cognitive dissonance you mention is related to more than the uncertainty in the prediction the science can make. It is also strongly tied up in the very different timescales of the processes involved – you mention the impossibility of experimental confirmation – this is sometimes true, but sometimes just not possible on a typical human timescale.

C: Are you concerned with the problem, endemic to scientific ecology, of 'formalization indeterminacy' – that is to say, the problem of multiple possible formalisations for one informal theory?

RW: Definitely, and with a host of other problems related to both how one creates a useful abstraction of the system of interest, how one goes about testing the model based on that abstraction against the often sparse data, and how one goes about specifying observational and experimental programmes that are driven by the data requirements of the emerging theory. In general, I find informal theory very frustrating. When you dig into problems of formalisation indeterminacy, you often find multiple meanings for the terms used in describing an informal theory, and these multiple meanings drive the multiple formalisations. Terms like 'stability' or 'interaction strength', widely used in community ecology, suffer greatly from this. This can be a great source of argument in the literature, but the arguments often hinge on semantics rather than significant scientific points.

C: Have any unanticipated conclusions been revealed by the dynamics yielded by your model, and if so how are these being pursued?

RW: I think all our conclusions were unanticipated. We really didn't work in a traditional 'formulate a hypothesis and test it' mode. I actually don't think much science does – papers get written as if that were the process, but in fact it is usually far more flexible and exploratory.

Our approach was really driven by the fact that Eric Berlow was a traditionally trained ecologist with a strong background in field experimentation. He approached the computational system as he would a field system, performed manipulations similar to those performed in the field and analysed the data like he would analyse manipulative experimental data. (With the advantage that the experimental manipulations were easy to perform so we could perform a lot of experiments and collect a lot of data!) One of the interesting findings is that the models could do a good job of predicting the results of the field experiments when it was clear that the interactions in those experiments were dominated by predator-prey interactions; but when there were obvious non-trophic (energy flow) interactions in the field system, the model, which only models energy flow, failed to predict the field system's response. This points to the importance of expanding these models to include more biological/ecological processes and interactions than the simple consumption interactions they are currently based on.

C: If your work confirms the assumption that diversity is positively correlated with stability, does that necessarily mean that the preservation or promotion of biodiversity is a suitable principle upon which to make environmental decisions? Is stability the goal of policy?

RW: As far as I can tell, policies don't have such abstract goals. They often don't seem to have a single, well-defined goal. Even if policies were set using some more abstract and scientifically defined goals, I don't think stability would be an appropriate goal, particularly given the environmental stresses on ecosystems. Given the importance of functioning ecosystems for so many of our material and psychological needs, preserving or maintaining ecosystem function seems to make sense as a policy goal, but this whole discussion quickly gets pretty far from science and into personal and societal values.

C: Your models suggest that 'increased robustness and decreased levels of web collapse are associated with increased diversity'.[8] Can one make a comparison in terms of food web stability between a cyclical biotic system of complex ecological communities that produce sufficient overall abundance to support human life without putting the integrity of the system in jeopardy, and the (comparatively less diverse) system of modern agriculture that produces output as a result of reliance on extracted mineral deposits from the Carboniferous Period? In other words, can the practice of industrial agriculture be called a food web at all? Or more generally, what is the status of anthropogenic systems within the biosphere – could they in principle be modelled in the same way as 'natural' systems?

RW: In principle, yes, modelling agricultural and 'natural' systems might be similar. In both systems there will be commonalities such as constraints due to limited amounts of energy, nutrients and water. When you build a model, you make assumptions (hopefully based on things that have been observed about the system of interest but sometimes based on convenience or your conceptual biases) about the processes that are important in the system and therefore need to be represented in the model. I suspect that the processes constraining industrial agricultural systems are so different than in 'natural' systems that the basic modelling framework would end up looking quite different.

C: Finally, is it a condition of 'ecological thought' that we reject anthropocentrism? The very idea of humans' 'destroying the planet' is an artefact of the limitations innate to human thinking (inability to think in terms of larger time-spans). From a truly non-anthropocentric perspective, there is little possibility of such an anthropogenic apocalypse – biological life will re-emerge in one form or another, after humans disappear; on the other hand, on a larger timescale, the extinction of the sun will take all life with it! Is 'non-anthropocentric thinking' a chimerical goal?

---

[8] Dunne and Williams, 'Cascading extinctions'.

RW: I'm sceptical that humans can be 'non-anthropocentric', and not even sure what it would mean; and from what I do understand of the idea I'm not sure that it's particularly desirable. When people try to develop ideas that are 'non-anthropocentric', for me it often ends up being either selfish or misanthropic. It's obvious and not very interesting that sooner than later humans will go extinct, that life will continue to evolve, that the earth will support life for a very long time after humans have disappeared. More interesting and I think more important, are the shorter-term questions about how to maintain not just livability but quality of life for the eventual nine billion and more people on the planet, all of whom are active participants in the biosphere, continuously interacting with a myriad of other organisms. Understanding how ecosystems function is just one of the many areas of human knowledge that must develop significantly if we are to succeed in this.

Thinking Ecology: The Mesh, The Strange Stranger, and the Beautiful Soul

Timothy Morton

I shall investigate what ecological interdependence means, philosophically and theoretically. We may then specify the beings with whom we are interdependent. As we proceed, we shall descend from seeming logical abstraction, through deconstruction, into an unbearable intimacy with others. Ecological thinking – what I call *the ecological thought* – is precisely this 'humiliating' descent, towards what is rather abstractly called 'the Earth'. Ecology is the latest in a series of great humiliations of the human, humiliations that might even constitute the human as such (in its humility, at least, if any). From Copernicus through Marx, Darwin and Freud, we learn we are decentred beings, inhabiting a Universe of processes that happen whether we are aware of them or not, whether we name those processes 'astrophysics', 'economic relations', 'the unconscious' or 'evolution'. The correct but surprising conclusion to draw from ecological humiliation, however, is not some form of nominalism or nihilism, but a politicised intimacy with other beings.

What is interdependence? Let's imagine a theorem called the Interdependence Theorem. It contains two simple axioms:

Axiom (1): $\forall a: \exists a: a = \sim(\sim a)$

Axiom (2): $\forall a: \exists a: a \supset \sim a$

Axiom 1 states that for every *a*, the existence of *a* is such that *a* consists of things that are *not not a*. Thus *a* is made of *not-a*'s, so the only way to define it is negatively and differentially. Thus *a* is *a* because it isn't *not-a*, while *not-a* is only *not-a* because it is *not a* – *a* and *not-a* are mutually determining. Axiom 1 states that things are only what they are in relation to other things.

Axiom 2 states that things derive from other things. While Axiom 1 is concerned with how things are (synchronically), Axiom 2 talks about origins (diachrony). In every case, things like *a* only exist such that a *not-a* exists. Nothing exists by itself and nothing comes from nothing.

Axioms 1 and 2 define interdependence across a range of phenomena. They summarise structural linguistics, for instance, because structuralism models signs as completely interdependent. The Interdependence Theorem also describes life forms. Diachronically, no life form exists that didn't arise from another one. And synchronically, life forms are different from each other in arbitrarily negative ways: there's no human-flavoured DNA as opposed to daffodil-flavoured DNA, for instance (the human genome is 35 percent daffodil). Since life forms are expressions of DNA, they differ from each other negatively rather than positively, since DNA is a language.

Since life forms depend upon each other the way signs depend upon each other, the system of life forms is isomorphic with the system of language. Since language is subject to deconstruction, the system of life forms must also be subject to deconstruction. What happens when we subject the system of life forms to deconstruction?

Derrida describes deconstruction as thinking 'the structurality of structure'. What type of structure? It's open ended: it has no centre and no edge. Because language is an arbitrary system of negative difference, there is no sign that stands somehow outside the system to guarantee the meaning and stability of the other signs. This means language is infinite, in the strong sense that we can never fully account for its meanings or effects. It also means that meaning depends upon meaninglessness. And that language as a system is not a thing, not an object, but a strange infinite network without inside or outside. The process that makes signs manifest as appearance and meaning is *différance*: the process of difference (synchronic) and deferment (diachronic). The meaning of a word is another word, and strings of signs only gain significance retroactively. The meaning of a sentence is a moving target. You will never be able to know exactly when the end of this sentence is until after you've read it elephant. Coherence, in order to be coherence, must contain some incoherence.

The same view applies to the system of life forms. They are made up of other life forms (the theory of symbiosis). And life forms derive from other life forms (evolution).

Because of the ecological emergency we have entered, we are now compelled to take account of this mind-changing view.

The implications of a deconstructive view of life forms are manifold:

(1) Life forms constitute a *mesh* that is infinite and beyond concept – unthinkable as such.

(2) Tracing the origins of life to a moment prior to life will result in paradoxes.

(3) Drawing distinctions between life and non-life is strictly impossible, yet unavoidable.

(4) Differentiating between one species and another is never absolute.

(5) There is no 'outside' of the system of life forms.

(6) The Interdependence Theorem is part of the system of interdependence and thus subject to deconstruction!

(7) Since we cannot know in advance what the effects of the system will be, all life forms are theorisable as *strange strangers*.

Let's sift through these implications.

(1) *Life forms constitute a mesh that is infinite and beyond concept – unthinkable as such.* This is not just because the mesh is too 'large' but also because it is also infinitesimally small. Differentiation goes down to the genomic level. There is no human-flavoured DNA, no daffodil-flavoured DNA.

Most of the terms I considered were compromised by references to the Internet – 'network', for example. Either that, or they were compromised by vitalism, the belief in a living substance. Web is a little bit too vitalist, and a little bit Internet-ish, so I guess it loses on both counts.

'Mesh' can mean both the holes in a network, and the threading between them. It suggests both hardness and delicacy. It has uses in biology, mathematics and engineering, and in weaving and computing – think stockings and graphic design, metals and fabrics. It has antecedents in *mask* and *mass*, suggesting both density and deception.[1] By extension, 'mesh' can mean 'a complex situation or series of events in which a person is entangled; a concatenation of constraining or restricting forces or circumstances; a snare'.[2] In other words, it's perfect.

If everything is interconnected, then there is no definite background and therefore no definite foreground. Charles Darwin sensed it in thinking through the implications of the theory of natural selection. His amazement is palpable:

> It is a truly wonderful fact – the wonder of which we are apt to overlook through familiarity – that all animals and all plants throughout all time and space should be related to each other in group subordinate to group, in the manner which we everywhere behold – namely, varieties of the same species most closely related together, species of the same genus less closely and unequally related together, forming sections and sub-genera, species of distinct genera much less closely related, and genera related in different degrees, forming sub-families, families, orders, sub-classes, and classes. The several subordinate groups in any class cannot be ranked in a single file, but seem rather to be clustered round points, and these round other points, and so on in almost endless cycles.[3]

---

[1] *Oxford English Dictionary*, 'mesh', n.1.a–c.

[2] *Oxford English Dictionary*, 'mesh', n.2.

[3] C. Darwin, *The Origin of Species*, ed. G. Beer (Oxford and New York: Oxford University Press, 1996), 105–6.

Every single life form is literally familiar, in that we are genetically descended from them. Darwin imagines an endlessly branching tree; 'mesh' doesn't suggest a clear starting point, and those 'clusters' of 'subordinate groups' in the quotation above are far from linear (they 'cannot be ranked in a single file'). Each point of the mesh is both the centre and edge of a system of points, so there is no absolute centre or edge. Still, the tree image marvellously closes out Darwin's chapter on natural selection, with its evocation of 'the Great Tree of Life, which fills with its dead and broken branches the crust of the earth, and covers the surface with its ever branching and beautiful ramifications'.[4] A 'ramification' is a branch and an implication, a branching thought.

(2) *Tracing the origins of life to a moment prior to life will result in paradoxes.* Sol Spiegelman's discoveries concerning RNA show how you can't draw a rigid narrow boundary between 'life' and 'non-life'. In order for life forms to begin, there had to be a strange, paradoxical 'pre-living life' made of RNA and self-replicating crystals such as a silicate (strange that silicon may be the element in question).

'RNA World' abolishes the idea of a palpable, fetishised life substance, the sort Naturephilosophy imagines as *Urschleim*, a sentient gel.[5] Curiously, the fantasy thing of idealist biology turns out to be this existential substance, as if idealism depended for its coherence on some metaphysical materiality. RNA World, by contrast, is structured like a language. At bottom, it is a set of empty formal relationships. This is the basis of a genuinely materialist biology.

---

[4] Darwin, *Origin*, 107.

[5] See I. H. Grant, 'Being and Slime: The Mathematics of Protoplasm in Lorenz Oken's "Physio-Philosophy" ', **COLLAPSE V**, 287–321.

Do you think a virus is alive? A virus is a macromolecular crystal that contains some RNA code. It doesn't reproduce as such, it only tells your cells to make copies of it. The cold virus is a huge twenty-sided crystal. If you think the rhinovirus is alive, then you probably should admit that a computer virus is also alive, to all intents and purposes. A computer virus also tells other pieces of code to make copies of itself. The life–non-life boundary is not thin and it is not rigid.

(3) *Drawing distinctions between life and non-life is strictly impossible, yet unavoidable.* This brings us to our third paradox. If 'pre-living life' is necessary for imagining the origins of life, then it is also the case that in the present moment, the moment of 'life' as such, the life–non-life distinction is also untenable. When we start to think about life, we worry away at the distinction between nature and artifice. Only consider the beings called viroids: Ten times smaller than virus, they are little circles of RNA code (Figure 1). They invade the transcription, rather than translation, parts of the host's reproductive machinery. Viroids are very ancient beings, dating back to RNA World.

Figure 1: Genome of PSTV (Potato Spindle Tuber Viroid)

(4) *Differentiating between one species and another is never absolute.* This is the lesson of Darwinism. 'Species' is a label that must be applied retroactively to life forms. There are

no species as such, no species-to-be, no point in evolutionary history to which we can point and say, 'Here is the origin of (say) *Homo Sapiens*'. *The Origin of Species* has a cheeky title, for it's one of the least teleological books ever written. Darwin demonstrates that all the categories of the life sciences – species, variation, monstrosity – collapse into one another.

(5) *There is no 'outside' of the system of life forms*. Once life 'begins' – and thinking this origin is practically impossible – everything else becomes linked with it. This is what most of us mean when we think ecologically: Everything is connected to everything else. There are strong metaphysical versions of this consequence (such as Gaian holism), and weak reductionist ones. I'm on the weak reductionist side.

This implication profoundly implies that there is no environment as such. Your DNA doesn't stop expressing itself at the ends of your fingers. A beaver's DNA doesn't stop at the ends of its whiskers, but at the end of its dam.[6] A spider's DNA is expressed in its web. From the perspective of the life sciences, the environment is nothing but the phenotypical expression of DNA code. This includes oxygen (anaerobic bacterial excrement). And it includes iron ore (a byproduct of archaic metabolic processes). You drive and fly using crushed liquefied dinosaur bones. You are walking on top of hills and mountains of fossilised animal bits. Most of your house dust is your skin. The *environment* looks like not a very successful upgrade of the old-fashioned term *nature*.

---

[6] See R. Dawkins, *The Extended Phenotype: The Long Reach of the Gene* (Oxford and New York: Oxford University Press, 1999).

(6) *The Interdependence Theorem is part of the system of interdependence and thus subject to deconstruction!* Since the Interdependence Theorem is only possible to state in language, and since it describes language itself, the Theorem recursively falls prey to its own premises.

The First Axiom states, 'Things are made of other things'. The Second Axiom states that 'Things come from other things'. Implication 4 asserts that we cannot rigorously differentiate between one species and another. Yet in order for Axiom Two to be valid, we must be able to distinguish one species from another! Since 'Things come from other things', there must be a distinction between one thing and another thing. Yet if we draw this distinction – if we think the word 'distinction' means something – there is no way one species can arise from another species. A dinosaur, a bird: there are continuities between them. And yet a dinosaur is not a bird. This is Zeno's paradox.

Axiom 2 is in still more trouble. Consider a candle and its flame. If there were no difference between the candle and its flame, then the flame could not arise, distinct from the candle. But if the candle is indeed different from the flame, then there is no way the flame can arise from it![7] Thus 'different from' and 'comes from' are now reduced to something meagre. The very terms of Axiom 2 have shrunk. They are themselves subject to Axiom 2!

Now consider Axiom 1, 'Things are made up of other things'. Think of a car: it's made of wheels, chassis, steering wheel, windows, and so on. Where is the car-ness in these components? Nowhere. Yet we can't say that just any old thing will do to put a car together: a car is made of just these components, not other ones. We have reduced Axiom 1 to bareness, by using Axiom 1 itself!

---

[7] I am adapting a Buddhist argument about emptiness. Nagarjuna, *The Fundamental Wisdom of the Middle Way*, tr. and commentary J. L. Garfield (Oxford and New York: Oxford University Press, 1995), 4, 44, 110–11, 160–1, 177, 190–1, 231–44.

Human beings are made up of arms, legs, heads, brains, and so on. So are birds, duck-billed platypuses, and sharks. These organs are made up of cells. So are plants, fungi, amoebae and bacteria. These cells contain organelles. These organelles are modified bacteria such as mitochondria and chloroplasts. They themselves contain DNA. This DNA is a hybrid fusion of bacterial DNA and viral insertions. DNA has no species flavour; moreover it has no intrinsic flavour at all. At the DNA level it becomes impossible to decide which sequence is a 'genuine' one and which is a viral insertion. In bacteria there exist plasmids that are like pieces of viral code. Plasmids resemble parasites within the bacterial host, but at this level, the host–parasite duality becomes impracticable. It becomes impossible to tell which being is a parasite, and which a host.[8] We have discovered components without a device of which they are the components – organs without bodies.[9] Indeed, the human genome contains endogenous retrovirus-derived sequences, and one of these, ERV-3, may confer immunosuppressive properties to the placenta, thus allowing embryos to coexist with the mother's body. You may only be reading this because a virus in your mum's DNA prevented her from spontaneously aborting you.[10]

---

[8] Dawkins, *Extended Phenotype*, 200–23, 226.

[9] I am inverting Deleuze and Guattari's phrase 'the body without organs'. See S. Zizek, *Organs without Bodies: Deleuze and Consequences* (New York and London: Routledge, 2003).

[10] M. T. Boyd, C. M. R. Bax, B. E. Bax, D. L. Bloxam, and R. A. Weiss, 'The Human Endogenous Retrovirus ERV-3 is Upregulated in Differentiating Placental Trophoblast Cells', *Virology* 196 (1993), 905–9.

At the DNA level, the whole biosphere is highly permeable and boundariless. There is less substance: 'Organisms and genomes may [...] be regarded as compartments of the biosphere through which genes in general circulate.'[11] How do we know we haven't learnt how to sneeze because rhinoviral DNA codes directly for sneezing as a means to propagate itself? Yet we have bodies with arms, legs, and so on, and we see all kinds of life forms floating and scuttling around, as if they were independent. It isn't an undifferentiated goo.

(7) *Since we cannot know in advance what the effects of the system will be, all life forms are theorisable as 'strange strangers'.* The Interdependence Theorem does not reduce everything to sameness. The way things appear is like an illusion or magical display. They exist, but not that much.

I use the phrase 'strange stranger' because Derrida's notion of the *arrivant* is the closest we have as yet to a theory of how the mesh appears up close and personal.[12] The arrivant is a being whose being we can't predict, whose arrival is utterly unexpected and unexpectedly unexpected to boot. The strange stranger is not only strange, but strangely so. They could be us. They are us.

STRANGE STRANGERS

Our encounter with other beings – and with our being as other – is *strange strangeness.* And with this we should drop the disastrous term *animal.* Haeckel's drawings of

igure 2: Ernst Haeckel, *Phaeodaria*, from *Kunstforen der Natur* (1904)

radiolarians show beings that look like geometrical plots rather than squishy organisms (Figure 2). That's because they are. The trouble with animals is that on some level they're vegetables, beings that just grow – isn't this the governing theme of many a horror story? And the trouble with vegetables is that they're algorithms. Consider *The Algorithmic Beauty of Plants*, a beautifully illustrated text readily available online.[13] Instead of illustrating plants, you can generate algorithms that plot them. Plant scientists now model plant growth using software like this. If an algorithm can plot a rose, surely the thing itself is a map of its genome, a three-dimensional expression of the algorithm's unfolding? I can only conclude that I, a supposedly sentient life form, am also subject to these rules.

Strange strangers are uncanny in the precise Freudian sense that they are familiar and strange simultaneously. Indeed, their familiarity is strange, and their strangeness is familiar. Strange strangers are unique, utterly singular. They cannot be thought as part of a series (such as species or genus) without violence. Yet their uniqueness is not such that they are utterly independent. They are composites of other strange strangers. We share their DNA, their cell structure, subroutines in the software of their brains. They are absolutely unique and so capable of forming a collective of life forms, rather than a *community. Community* is a holistic concept that is greater than the sum of its parts. Since the Interdependence Theorem implies that there is no whole (such as 'animals', Nature and so on), *community* can only ever be a conceptual construct.

---

[13] P. Prusinkiewicz and A. Lindenmayer, *The Algorithmic Beauty of Plants*, with J. S. Hanan, F. D. Fracchia, D. Fowler, M. J. M. de Boer, and L. Mercer (Przemyslaw Prusinkiewicz, 2004); available at http://algorithmicbotany.org/papers/.

By contrast, *collectivity* signifies the conscious choosing of a coexistence that already exists whether we think it or not. Yet because of strange strangeness, this choosing cannot be a totalising grip, or final pinning-down. Collectivity is 'to come', in the sense that it addresses the *arrivant*, who is necessarily to come, evanescent and melting to the exact same extent as she, he or it (how can we tell for sure?) is disturbingly 'there'.

These are the precise coordinates of the global warming crisis. We are faced with the ability to choose our coexistence with other life forms and accept responsibility for global warming; or reactively to wait for 'the market' to sort it out. (Funny how we can imagine the end of the world as we know it, but not so well the end of capitalism.) The discourse of community cannot help us to jump across this open historical moment into the future, because it is intrinsically conservative, if not reactionary, if not, at times, fascist. Community implies a boundary between inside and outside, which implies inclusion and exclusion: scapegoating. The antagonistic energy of the community is pasted onto the scapegoat, who is then sent outside the community to purge it of its contradictions. Collectivity posits that the antagonisms are directly a feature of coexistence as such. Thus these antagonisms have to do with an inadequate politics of collectivity itself, which must henceforth be revised to address them. The two models are deeply asymmetrical. It is not that collectivity embraces more life forms: it is not just a bigger, 'new and improved' community.

If we are to achieve a radical ecological politics, then we must acknowledge the difficulty of the strange stranger. We are faced with an apparent paradox: materialism and what mistakenly goes under the sign of 'mysticism' are inextricably interlinked. Our ecological existence is 'nearer than breathing, closer than hands and feet'.[14] We've got others – rather, others have got us – literally under our skin.

FURTHER IMPLICATIONS

What conclusions can we draw?

There is no nature, never was, never will be. There is therefore no 'world' as such. Indeed, there is no ontology – no ontology is possible without a violent forgetting of the intrinsically incomplete, 'less than' level we have been describing. Thus no phenomenology is truly grounded in reality. Ecophenomenology therefore contains an internal limit caused by the humiliating paucity of the 'incomplete' ontic level.

Science and capitalism have ensured that we are now directly responsible for what we used to see outside ourselves as Nature, if only in the negative. It is now the task of philosophy and politics to catch up with, and I hope surpass, this state of affairs. What has been called Nature (I capitalise it precisely to 'denature' it) is now on 'this' side of history and politics. That's the difference between *weather*, which just happens to us, and *climate*. We can't see climate directly, but we can take direct responsibility for it, bring it on 'this' side of history. Walter Benjamin asserts that when weather becomes a topic for collective action (as now), it stops being that thing 'over yonder' called the weather. It 'stand[s] in the cycle of the eternally selfsame, until the collective seizes upon [it] in politics and history emerges'.[15]

[14] George Morrison, *The Weaving of Glory* (Grand Rapids, MI: Kregel Publications, 1994), 106.

[15] I develop this in *Ecology without Nature: Rethinking Environmental Aesthetics* (Cambridge, Mass. and London: Harvard University Press, 2007), 160–9.

The same goes for the strange stranger as opposed to 'the animal'. We shall soon regard the phrase 'the animal question' with as much queasy horror as 'the Jewish question' – and for the same reasons.

'Let it be' is over. Heideggerian environmentalism fails at a fundamental level. Since being itself is in question, there is not much to 'let be' in the first place. We are faced with a Romantic irony in which we cannot rid ourselves of our conscious implication in the interconnected Universe. Our minds, in short, are part of the interdependence. There is no 'reality' in which we are 'embedded' separate from our awareness of this reality. And yet, and at the very same time, there is not nothing at all. The Interdependence Theorem is not nominalism, let alone nihilism.

For Heidegger, Being lets things be. Poetry gives us unique access to this letting-be quality of Being. Cue a thousand environmental maxims, poems, attitudes. But what do we let be? When letting-be becomes a political question, the Being really hits the fan. Do we let Exxon be? Do we let global warming be? Do we let the Sixth Mass Extinction Event (for which we ourselves are responsible) be? The Interdependence Theorem means that Nature becomes historical, and therefore political. Letting be therefore becomes a tacit choice to maintain the status quo.

There are Heideggerians who seriously suggest this. Interventions into the substance of reality are seen as inevitably failed attempts to not let be. The ideological language of immersion in the lifeworld – profoundly environmentalist language, derived from Heidegger – is complicit with current social and ecological conditions. This sounds counterintuitive, but it's no different than driving past what looks like two separate buildings that turn out to be part of the same structure, a type of parallax. Insisting on our embeddedness (like Iraq War reporters) in the 'world' is – shocking thought – part of the problem. In particular, this is because ideas come bundled with attitudes. While the language of embeddedness insists that we are up close and personal with reality, the attitude it codes for is cosy, vicarious, aesthetic distance.

'Leave no trace' was a slogan from an environmentalist movement about picking up after yourself when you go hiking. 'Leave no trace' is a translation of 'Let it be'. Imagine Heidegger in a hide: the stupefied, plangent hush of his prose tells of a huntsman waiting for Being, with a gun or binoculars – even if the gun is only the gun of the fascinated gaze. "Be vewy vewy quiet," as Elmer Fudd says, on the hunt for Bugs Bunny.[16] Letting-be conjures the 'meditative' quiet of the forest. Here is a Buddhist lama writing what I hold to be the definitive passage on the affinity between contemplativeness and violence. The lama is recounting the words of a visitor from the city of Birmingham to his monastery in southern Scotland. The visitor was a little hesitant to do any actual meditation:

> Well, it's nice you people are meditating, but I feel much better if I walk out in the woods with my gun and shoot animals. I feel very meditative walking through the woods and listening to the sharp, subtle sounds of animals jumping forth, and I can shoot at them. I feel I am doing something worthwhile at the same time. I can bring back venison, cook it, and feed my family. I feel good about that. [17]

[17] Chögyam Trungpa, Rinpoche, *Training the Mind and Cultivating Loving-Kindness* (Boston: Shambhala, 1993), 35–6.

Let it be! Pull! Bang! What a fantastic sight! Shhh, quiet, I'm trying to kill this rabbit. Quietly, meditatively, I insert my knife gently and smoothly into its neck, mindfully and meditatively I slit its throat … In the rabbit's blood I can smell the quiet of the fields, the 'toilsome tread' of the paws on their daily round, the search for something to nibble … this rabbit corpse is a moving environmental poem, like a pair of old shoes in a Van Gogh painting … mmm …

> From the dark opening of the worn insides of the shoes the toilsome tread of the worker stares forth. In the stiffly rugged heaviness of the shoes there is the accumulated tenacity of her slow trudge through the far-spreading and ever-uniform furrows of the field swept by a raw wind. On the leather lie the dampness and richness of the soil. Under the soles slides the loneliness of the field-path as evening falls. In the shoes vibrates the silent call of the earth, its quiet gift of the ripening grain and its unexplained self-refusal in the fallow desolation of the wintry field. This equipment is pervaded by uncomplaining anxiety as to the certainty of bread, the wordless joy of having once more withstood want, the trembling before the impending childbed and shivering at the surrounding menace of death.[18]

I have recently been accused of not knowing what Nature is because I have never killed an animal that I've subsequently eaten. This is a criterion that I am happy not to have fulfilled. Heideggerianism, the quintessence of the contemplative ecophenomenological mode in which a lot of Nature-speak now addresses us, is marked by a trace of violence, an unspeakable violence towards the world it so lovingly appears to reveal to us. The very worn insides of the peasant shoes about which Heidegger rhapsodises so beautifully in his essay on the origin of the work of art are made from leather, which is animal skin. A certain kind of intellectuality revels in the anti-intellectualism afforded by Heidegger's language, which demands a passive submission almost taboo elsewhere in the modern Humanities. This passivity finds its virtual analogue in the happy, servile authenticity of the peasant woman, which Heidegger deduces from Van Gogh's shoes. Contemplation here appears deep but not genuinely disturbing: it is a superficial vicarious experience of an imaginary other's suffering. Substitute a gas chamber or Hiroshima human shadow, or a simple pair of Nikes, for the shoes, and this supposed contemplativeness becomes unnerving. You can imagine committing a murder in a beautiful, mindful, Heideggerian way. Aesthetically powerful descriptions of the natural world, then, are not only a waste of time, but might unwittingly aid the 'other side' of the contemporary coin, which sees the world as an exploitable resource or as objects of instrumental reason (the difference between a cow and beef would be the application of this instrumentality).

---

[18] M. Heidegger, 'The Origin of the Work of Art', in *Poetry, Language, Thought*. Trans. A. Hofstadter (New York: Harper and Row, 1971) 15–87 (33–4).

Heidegger's contemplative language is so seductive that in countless ecocritical and ecotheoretical texts, he is often the sole representative of a noninstrumental point of view. We cannot ignore this rhetorical mode, and not just because there are many adaptations of it. The Heidegger meme is seductive because it speaks to something profound, something often called spiritual. In order to get over Heidegger, we have to go underneath him.

Ecology is about intimacy. Instead of insisting on being part of something bigger, ecological thinking leads to a different framework: intimacy, not holism. Thus organicism is no longer a workable mode of aesthetics and politics. Organicism believes that form can fit content like an invisible glove, leaving no trace. Organic form is greater than the sum of its parts. Most environmentalisms – including systems theories – are organicist. World fits mind and mind fits world, as William Wordsworth asserted. In the margins of his copy of the poem where Wordsworth laid this out, William Blake wrote: 'You shall not bring me down to believe such fitting & fitted … & please your lordship'.[19]

Desire is inescapable in ecological coexistence. Yet environmentalism as currently formulated tries to transcend the contingency of desire, claiming that its desires if any are natural. Organicism partakes of environmentalist chastity. 'Nature loving' is supposedly chaste (impossible formula! like courtly love, or Neoplatonic love), and is thus slave to masculine heteronormativity, a performance that erases the trace of performance.[20] 'Leave no trace'. If you look like you are 'acting' masculine, you aren't. Masculine is Natural. Natural is masculine.

Organicism is a performance of no-performance. It is 'un-perversion', with all the ambiguity a double negative can muster, a desire that erases its trace as soon as it appears. Organicism articulates desire as erasure, erasure-desire. The curtain rises on a pregiven holistic world. But interdependence is not organic: it's differential. Things only look like they fit, because we don't perceive them on an evolutionary or geological time scale. Sphex wasps paralyse crickets to feed to their young. If you move a paralysed cricket away from in front of the burrow that the Sphex wasp who paralysed her is inspecting (for the presence of grubs), the wasp will repeat the same behaviour, moving the cricket back meaninglessly to the entrance of the hole, without dragging her in.[21] 'Nature' dissolves when we look directly at it, into assemblages of behaviours, congeries of organs without bodies. Nature looks natural because it keeps going, and going, and going … like the undead. And because we keep on looking away, keeping our distance, framing it, sizing it up.

[20] See T. Morton, 'Queer Ecology,' (PMLA, forthcoming).

Blake heard the voice of authority in organicism. Authoritarian organicism gains its power by naturalising difference. Nature is unmarked ('leave no trace'). It is established by exclusion, and then by the exclusion of exclusion. We must rediscover what has been excluded from the book of Nature. Ecology must unthink *ecologocentrism*. I mean precisely a version of what Derrida calls logocentrism, the creation of a metaphysical scheme that sets up a sign as a Master signifier that magically stands outside the system of meaning, and guarantees the meaning and coherence of all the other signs.[22] Once this is established, we know what's in and what's out, what's up and what's down, what's marked and what's unmarked. The Interdependence Theorem does not allow this knowledge to congeal.

Perhaps we could give ecologocentrism the slip by saying that Nature is beyond concept. Beyond concept, Nature is, a Nature for which there are no words. But we are already using words to describe this wordless Nature. Thus a negative theology of the environment must fall prey to the deadly logos it wishes to transcend.[23] Thinking you can escape metaphysics by outlining a hyperessential being beyond being only repeats the problem.[24] 'Nature is not unnatural.' A negative theology of the environment is the ultimate chastity – it refuses even to name the non-name, refuses even to non-name it.

NO MORE BEAUTIFUL SOUL

Intimacy means we are caught in desire. Hegel held that philosophy wasn't just about ideas, it was about attitudes towards ideas. These attitudes were as yet unthought ideas, ideas that hadn't yet been realised consciously. If, as Donald Rumsfeld has claimed, there are known knowns, known unknowns, and unknown unknowns, there are also, as Zizek adds, unknown knowns – things that we know, but we don't know that we know them: the unconscious, if you like psychoanalysis. Once you realise what your attitude towards an idea is, that attitude itself becomes an idea, towards which you have yet another attitude, which you'll need to figure out – and so on in a progression that Hegel calls the phenomenology of spirit.

Like a vanishing point in a perspective picture, ideas select for certain ways of being understood. Some call this strange feature ideology. Ideology is not well understood, because we think it means belief, which we think means an idea you are holding onto tightly – these two assumptions are themselves ideological, and obscure what ideology is. Attitudes are automated features of ideas – they just pop up when you have them. They aren't subjective states independent of ideas. That's why attitudes are hard to get rid of: they're hardwired into 'that' side of reality, rather than 'this' one. If it were just a matter of prejudice, we'd all have grown up long ago. But as Marx saw, the attitude that sees attitude as prejudice (we call it the Enlightenment) suffers from its own blind spots, having do with illusions of freedom and autonomy.

[24] J. Derrida, 'How to Avoid Speaking: Denials,' in H. Coward and T. Foshay (eds.), *Derrida and Negative Philosophy* (Albany: State University of New York Press, 1992), 74.

Nature seems incontestably 'there' – as many have reminded me, because what I need, as a theory guy, is a good strong dose of it to set me straight. In *Environmental Literary Criticism*, Karl Kroeber says that what 'postmodern theorists' need is a night out in a Midwestern thunderstorm, a ritual hazing that now sounds horribly like waterboarding.[25] But is the 'thereness' – more like the 'over-thereness' – of nature a lie in the form of the truth? What attitude is this truth enabling?

Hegel gave the attitude a name: the Beautiful Soul, which he found typified in Romanticism.[26] The Beautiful Soul suffers from seeing reality as an evil thing 'over yonder'. Is this not precisely the attitude of many forms of environmentalism? Ironically, the attitude that *nature* enables is the dreaded dualism, Cartesian and otherwise, from which nature-speak from Romanticism to environmentalism has sought to extricate itself. Nature is 'over yonder'; the subject is 'over here'. Nature is separated from us by an unbridgeable ontological wall, like a plate glass window – plate glass was the Romantic-period invention that enabled shops to display their wares as if they were in a picture frame, and therefore belonged to another order of reality. Plate glass is a physical byproduct of a quintessentially Romantic production, the consumerist. Not the consumer, but the consumerist: someone who's aware that she is a consumer, someone for whom the object of consumption defines her identity, along the lines of that great Romantic phrase, invented once by the gourmand Brillat-Savarin and once again by Feuerbach: 'You are what you eat'.[27]

[26] G. W. F. Hegel, *Hegel's Phenomenology of Spirit*, trans. A.V. Miller (Oxford: Oxford University Press, 1977), 383–409.

This phrase implies that the subject is caught in a dialectic of desire with an object with which it is never fully identical, just as Wile E. Coyote never catches up with Roadrunner in the cartoon. If Wile E. Coyote ever did catch Roadrunner, he would eat Roadrunner, at which point Roadrunner would cease to be Roadrunner and would become Wile E. Coyote. There is in effect a radical separation between subject and object. Yet consumerism implies an identity that can be collapsed into its object, so we can talk of vegetarians, hip-hop fans, opium eaters, and so on.

One style stands out, a meta-style that Campbell calls bohemianism and I call Romantic consumerism.[28]

Morton, *The Poetics of Spice: Romantic Consumerism and the Exotic* (Cambridge and New York: Cambridge University Press, 2000), 5, 9, 50–1, 57, 107–8; 'Consumption as Performance: The Emergence of the Consumer in the Romantic

This type of consumerism is at one remove from regular consumerism. It is 'consumerism-ism', the realisation that the true object of desire is desire as such. Romantic consumerism is window-shopping, enabled by plate glass, and now by browsing online, not consuming anything but wondering what we would be like if we did. In the Romantic period, reflexive consumerism was limited to a few avant-garde types: the Romantics themselves. To this extent Wordsworth and De Quincey are only superficially different. Wordsworth figured out that he could stroll forever in the mountains; De Quincey figured out that you didn't need mountains, if you could consume a drug that gave you the feeling of strolling in the mountains (sublime contemplative calm, and so on). Nowadays we are all De Quinceys, *flâneurs* in the shopping mall of life. This performance is ever more pervasive: we haven't really exited the Romantic period.

Romantic consumerism can go one step higher than the Kantian aesthetic purposelessness of window-shopping, when it decides to refrain from consumerism as such. This is the attitude of the boycotter, who emerges as a type in the proto-feminism of the Bluestocking circle in the 1780s and 1790s, an attitude which Percy and Mary Shelley, and many others, practiced. The product boycotted was sugar, which was sentimentally described as the crystallised blood of slaves. The boycotter transmuted objects of pleasure into objects of disgust. To display good taste, you have to know how to feel appropriate disgust, how to turn your nose up at something. The zero degree performance of taste would be spitting out something disgusting, or vomiting.

Period,' in T. Morton (ed.), *Cultures of Taste / Theories of Appetite: Eating Romanticism* (New York and London: Palgrave, 2004), 1–17.

The height of good taste is abstaining from sugar, and spice if you are one of the Shelleys, who held correctly that spice was a product of colonialism.

The attitude of the boycotter is that she has exited consumerism, but this attitude is itself a form of consumerism. It's a performance of a certain style of aesthetic judgment. Believing you've exited consumerism might be the most quintessentially consumerist attitude of all. In large part this is because you see that the world of consumerism is an evil world. 'Over yonder' is the evil object, which you shun or seek to eliminate. 'Over here' is the good subject, who feels good precisely insofar as she has separated from the evil world.

Hegel's Beautiful Soul claims precisely to have exited the evil world. Hegel doesn't claim that the world may or may not be evil – what is wrong with the Beautiful Soul is not that it's prejudiced and rigid. The world is not some object about which we can have different opinions. The problem is far subtler than that. It's that the gaze that constitutes the world as a thing 'over yonder' is evil as such. The environmental fundamentalism that sees the world as an essential, living Earth that must be saved from evil, viral humans is the very type of the Beautiful Soul's evil gaze. Ironically then, this environmentalism is not spiritual, if by spiritual we mean transcending the material world, but deeply committed to a materialistic view that sees evil as a concrete thing that must be eliminated.

This environmentalism is a form of anti-consumerism, which puts it at the summit of consumerism, not beyond it. It is the most rarefied and pure form of consumerism. Beautiful Soul Syndrome (BS) plagues it, because it sees consumer objects, and consumerisms (the various styles), as so many reified things 'over yonder', from which it distances itself with disdain. How do we truly exit from the Beautiful Soul? By taking responsibility for our attitude, for our gaze. On the ground this looks like forgiveness. We are fully responsible for the present environmental catastrophe, simply because we are aware of it. No further evidence, such as a causal link that says humans brought it about, should be required. Looking for a causal link only impedes us from assuming the direct responsibility that is the only sane, ethical response to global warming and the Sixth Mass Extinction Event. It's worse than a waste of time to keep trying to convince people that environmentalism is a right way of thinking – a right attitude. The current ecological emergency should have proved to us that the environmentalist attitude – that there is a 'world' that is separate from me, that nature exists apart from human society – is not only wrong, but also dangerously part of the problem, if only because it provides a good alibi while impeding us from doing anything about our dilemma. The message of ecological awareness should not be 'We Are the World' (that awful charity song) but rather, 'We Aren't the World'. And never were: letting go of a fantasy is even harder than letting go of a reality.

Beautiful Soul Syndrome wants to induce the correct aesthetic appreciation of the world. But this aesthetic attitude can never truly become an ethical one. Kierkegaard terrifyingly showed how insidious Beautiful Soul Syndrome is, in his narrative of the seducer in *Either/Or*.[29] Aestheticisation is synonymous with evil because it holds the world at a distance from which to size it up. Thus the attitude that says, 'We need more evidence on global warming before we act' ironically joins the attitude that says, 'If only you could experience nature in the raw, you wouldn't have these evil beliefs about destroying it.' In both cases, violence hides beneath projections of innocence. Both statements come bundled with attitudes of awaiting some compelling, unmediated aesthetic experience issuing from beyond the subject. They are both examples of Beautiful Soul Syndrome: both require a certain aesthetic distance, an evaluative, pseudo-contemplative, 'meditative' stance.

---

[29] S. Kierkegaard, *Either/Or: A Fragment of Life*, tr. and intro. A. Hannay (Harmondsworth: Penguin, 1992), 243–376.

If you beat up the Beautiful Soul, however, and leave it bleeding to death in the street, aren't you also a victim of Beautiful Soul Syndrome? However much you try to slough off the aesthetic dimension, doesn't it stick to you ever more tightly? At a certain limit, transcending Beautiful Soul Syndrome means forgiving the Beautiful Soul, recognising that we are responsible for this Syndrome, whether we picture ourselves that way or not. The only way out of the problem is further in: jumping into our hypocrisy rather than pretending to be disillusioned and beyond ideology, without attitudes. This is a test case for our ability to progress in social collectivity. It means dropping various supporting concepts that provide the background against which regular thinking takes place: *nature, environment, world, life*. We can't have our cake and eat it too: that's consumerism, which is Beautiful Soul Syndrome. The only way out is in and down, which is why I call my approach *dark ecology*.

Dark ecology realises that we are hopelessly entangled in the mesh. Dark ecology finds itself fully responsible for all life forms: like a detective in a noir movie, it discovers it's complicit in the crime. Dark ecology is melancholic:

melancholy is the Earth humour, and the residuum of our unbreakable psychic connection to our mother's body, which stands metonymically for our connection with all life forms. The irony of dark ecology is like being caught in your own shadow. Hegel disliked Romantic art because its ironies reminded him of the Beautiful Soul. He describes it in hauntingly environmental terms in his lectures on aesthetics.[30] Environmental awareness is, finally, a sense of irony, because it is through irony that we realise that we might be wrong, that identity might not be as solid as we think, that our own gaze might be the evil that we see.

Fossils of Time Future: Bunkers and Buildings from the Atlantic Wall to the South Bank

Owen Hatherley

HOMELAND PROTECTION STYLE

A couple of years before his death, J.G. Ballard wrote an essay for the *Guardian* on Modern architecture, as part of a tie-in with the highly successful *Modernism – Designing a New World* exhibition at the Victoria and Albert Museum. This exhibition can be seen as the moment where the British middle class fully reclaimed modern architecture and design, after an interregnum of post-modernist eclecticism – but, in much the same way that a Labour government was no longer meaningfully a Labour government, this was not the same modernism. Accordingly, a line was established where modernism, as a purist, clean and hygienic aesthetic developed in the 1920s, leapt over the dissonant, mutated, megastructural, 'Brutalist' modernism of council housing and 'comprehensive redevelopment' that occurred after 1945, picking up the thread again in the 1990s, with the Blairite tasteful style of architects like Allies and Morrison or property developers such as Urban Splash, with (this time a more brightly coloured) minimalism once again the reigning aesthetic. Of the many articles in the press celebrating the V&A exhibition, a Modernism that didn't fit the rubric of 'sweetness and light' was explained away briefly as a perversion, a parody, of the original idea. In the process, Modernism was denuded too of its attachment to left-wing politics, and of its close relation to the technological acceleration enabled by total war.

In contrast, Ballard concentrated on a warped Modernism, one that can barely even be described as architecture – the Atlantic Wall that was designed to protect against the inevitable 'second front' in the Second World War, a gigantic construction project designed by the Organisation Todt, the Nazi engineering force that had been responsible for the Autobahn network, and built by thousands of slave labourers. There has long been an urge to find the totalitarian smoking gun in discussions of Modernism, the missing link that connects unfashionable aesthetics and unpleasant politics. So, while the official architecture of Nazism eschewed Modernism for a mixture of monumental classicism and the Teutonic vernacular they called the *Heimatschutzstil* ('homeland protection style'), the suppressed aesthetics of expressionism and functionalism broke out in 1942, in the form of these completely utilitarian structures for the protection of the doomed thousand-year Reich. Built by slave labourers from reinforced concrete and placed along the French coast, these bunkers, blockhouses, observation posts, submarine bases and gun placements were largely forgotten by the 1960s.

It was at this point that Ballard became obsessed with them. He writes, retrospectively:

> Walking along the beach some years ago, I noticed a dark structure emerging from the mist ahead of me. Three storeys high, and larger than a parish church, it was one of the huge blockhouses that formed Hitler's Atlantic wall, the chain of fortifications that ran from the French coast all the way to Denmark and Norway. This blockhouse, as indifferent to time as the pyramids, was a mass of black concrete once poured by the slave labourers of the Todt Organisation, pockmarked by the shellfire of the attacking allied warships.

Rather than eliciting a feeling of relief that the blockhouses were an unoccupied remnant of a finished conflict, they seem instead to be 'waiting for the next war', and appear moreover to have developed outgrowths into the rebuilt British cities, those that were in some cases destroyed by V2s shot from these very bunkers:

> The scattered rubbish and tang of urine made me think of structures closer to home in England – run-down tower blocks and motorway exit ramps, pedestrian underpasses sprung from the drawing boards of enlightened planners who would never have to live in or near them, and who were careful never to stray too far from their Georgian squares in the heart of heritage London [...] Whenever I came across these grim fortifications along France's Channel coast and German border, I realised I was exploring a set of concrete tombs whose dark ghosts haunted the brutalist architecture so popular in Britain in the 1950s. Out of favour now, modernism survives in every high-rise sink estate of the time, in the Barbican development and the Hayward Gallery in London, in new towns such as Cumbernauld and the ziggurat residential blocks at the University of East Anglia.

This list was an roll-call of what Modernism had come to after World War Two, seeing as its 'heroic' era had allegedly died when the Atlantic Wall was built – and more convincingly, when the possibility of a belief in progress had been irrevocably shaken, after the white-walled, antiseptic aesthetics of the 1920s had failed to prevent the atavism and brutality of the 1940s – an 'architecture of death', where thin, smooth rendered walls were replaced by thickly abrasive concrete surfaces. Ballard writes regretfully, almost as an admission of defeat, that this project for the transformation of life was finally capable only of erecting funerary structures, as the transformation in life that it aimed for was not achieved. Seeing as Ballard is on record as loathing postmodernist architecture and the fantasies of old England embodied in Barratt Homes and Poundbury, we should read the following as the lament of someone disappointed in our failure to live up to the modernist ideal:

> I have always admired modernism and wish the whole of London could be rebuilt in the style of Michael Manser's brilliant Heathrow Hilton. But I know that most people, myself included, find it difficult to be clear-eyed at all times and rise to the demands of a pure and unadorned geometry. Architecture supplies us with camouflage, and I regret that no one could fall in love inside the Heathrow Hilton. By contrast, people are forever falling in love inside the Louvre and the National Gallery.

This rather peculiar essay ruminates inconclusively, but it pulls together all the elements of modernism which are most uncomfortable to the shiny Ikea Modernism of riverside luxury flats and glass trading floors. In the process it reminds us of the atavism in modernism itself, the places where, at the fringes of the modern movement, primal impulses and prehistoric building forms recur. The Atlantic Wall is a project as ancient as it is modern, whose forms evoke pyramids, hill forts, and, like Denys Lasdun's Halls of Residence for UEA, where the concrete has a similarly verdant, semi-rural setting, 'ziggurats'. This is an hieratic architecture, one where rationalism is forced into the service of the irrational. Ballard first traversed this landscape fictionally in the mid-1960s, in the short story *The Terminal Beach.* Although the landscape of bunkers and beaches is here rescheduled to the aftermath of a Third World War, Ballard's descriptions are clearly informed by his exploration of the Atlantic Wall. *The Terminal Beach* is what happened when, after lying in wait, the bunkers regained their functions, with the later forms of Cape Kennedy or Eniwetok transplanted onto the Normandy coast. The protagonist, Traven, treats the post-catastrophe landscape as a kind of mental experiment, as if researching the psychic processes that led to the apocalypse, only to find the structures taking him back far further:

> The desolation and emptiness of the island, and the absence of any local fauna, were emphasised by the huge sculptural forms of the target basins set into its surface [...] roadways, camera towers and isolated blockhouses, together forming a continuous concrete cap upon the island, a functional, megalithic architecture as grey and minatory (and apparently as ancient, in its projection into, and from, time future) as any of Assyria and Babylon [...] Here, the key to the present lay in the future. This island was a fossil of time future, its bunkers and blockhouses illustrating the principle that the fossil record of life was one of armour and the exoskeleton.

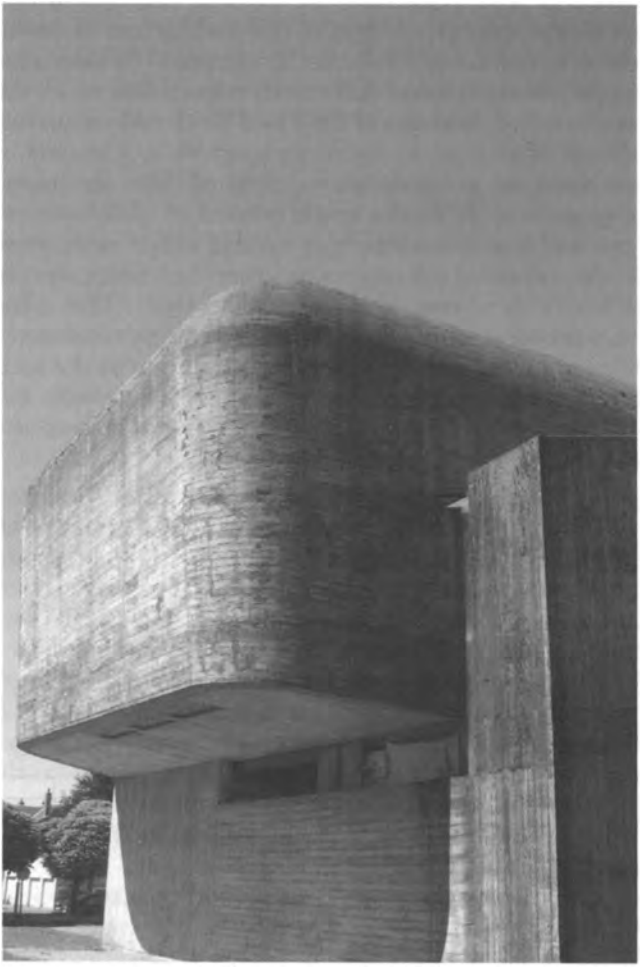
The bunkers recur in the psychic landscapes of *The Atrocity Exhibition* a few years later, where a similar protagonist fuses them with advertising hoardings, television, skyscrapers, the interiors of laboratories, and the prospect of 'sodomising the Festival Hall'. The Atlantic Wall becomes a pop landscape, another part of the media storm that the novel's researcher subjects himself to:

> Partly concealed by the sunlight, the camouflage patterns across the complex of towers and bunkers four hundred yards away revealed half-familiar contours – the model of a face, a posture, a neural interval. A unique event would take place here. Without thinking, Travis murmured 'Elizabeth Taylor'. Abruptly there was a blare of sound above the trees.

BUNKERS AS ALTARS

It's difficult to establish direct links between the Atlantic Wall and the Modern architecture that followed the Second World War, but there is one example where the influence was clear and publicly stated. Ballard's notion of the Atlantic Wall as an ancient formation, something primitive and monumental, was paralleled at exactly the same point by the researches of the (then) young architect Paul Virilio. In 1958, Virilio began a project to collate and catalogue the structures which would be pulled together into the 1975 book and exhibition *Bunker Archaeology*. This book was the first outside the field of military history to give these extraordinary places an extended, historical examination, in a mix of philosophical meditation on their 'meaning' and political investigation of their purpose. Virilio's account was divided under headings in which expected subjects such as 'Military Space' or 'The Fortress' were interspersed with a chapter on the notion of 'The Monument', in which he managed to find an almost spiritual element to this architecture of death, claiming that it could fulfil the 'monumental function that modernist architecture deliberately refused (but which the monumental classicism of the Third Reich had no qualms about)'. Elsewhere, he has as an epigraph to a chapter of his haunting, gorgeous photographs of these structures, a quote from Hölderlin much beloved of phenomenologists and sentimentalists, here making rather more sense in the context of military architecture: 'but where danger is found, there rises also that which saves'. This takes on a double-meaning, in that these seemingly monstrous, ferocious objects are formally dictated mostly by the need for protection, in their attempt to 'save' those inside; but Virilio takes it literally, in that the Atlantic Wall becomes a model for a new religious architecture.

In this he was preceded, perhaps, by Le Corbusier, whose post-war buildings for the Catholic Church – the chapel at Ronchamp, La Tourette monastery – use a bare, shuttered, 'crumbly' and searingly tactile concrete which has more in common with the material of these Nazi bunkers than that which he rendered and smoothed-over into the streamlined perfection of his 1920s 'Purist Villas'. This was little more than coincidence, spurred by Le Corbusier's accidental 'discovery' of *beton brut* after budget cuts in the Marseilles *Unité d'Habitation*, inadvertently creating 'Brutalism'. Virilio traces from this an elective affinity, bringing the latent connections to the surface, heightening their apparently religious aura and their extreme modernity, particularly in the case of bunkers surviving in small towns, which unlike the 'wall' on the beach, could gradually become accepted, quotidian:



Virilio's 'Bunker Church'. Photograph © Jorge Ayala.

> … the sky playing between the embrasure and the entrance, as if each vast casemate were a little ark, or an empty temple minus the cult […] these concrete altars built to face the void of the oceanic horizon […] these solid masses in the hollows of urban spaces, next to the local schoolhouse or bar, shed new light on what 'contemporary' has come to mean. Why continue to be surprised at Le Corbusier's forms of modern architecture? Why speak of 'Brutalism'?

Unlike the post-war rebuilding of blitzed cities along rationalist lines, the Atlantic Wall provided an architectural model for a shattered, traumatised world, and for Virilio at least, a possible model for salvation from this fragmentation and psychosis.

Their very method of construction, to the design of engineers such as Fritz Todt or Ulrich Finsterwalder, suggested the modernity of total war, a science of compaction and impact, where the concrete structure is not a frame, not built from the ground up, but a poured mound, where 'the centre of gravity replaces the foundation'. It is the manner in which the bunker is tailored to protect the human being against modern arms that is the source of its appropriateness for modern design. Far from being an aggressive architecture, for Virilio it is defensive: 'the imposing forms are the consequence of the adversaries' arms, of the fire power of those who rescued us, of our own armies.' The photographs show an architecture which, owing in part to the exigencies of camouflage, manages to be alternately extremely jarring and, in conservative architectural parlance, 'contextual'. While some of the structures seem to be a grotesque metamorphosis of the architecture of the twenties – especially the work of Erich Mendelsohn, with the expressionist curves recalling his

Einstein Tower and the gun emplacements an accidental parody of the ribbon windows of his department stores – others are more archaic. One bunker is disguised as a chapel, another insinuates itself into a barrow, evoking the ceremonial burial grounds of Mycenaean Greece; 'the continuance of the site', notes Virilio, 'conflates funerary architecture with military architecture.' Finally, in 'The Aesthetics of Disappearance', Virilio's photographs show the bunkers overcome by nature, sinking into the beach, overgrown with grass and lichen, gradually becoming earthworks.

The atavism of the Wall is most obviously associated with its part in the Nazi project, with its use of advanced technology in the service of the primal lunacy of blood and soil – but Virilio would adopt its forms for an atavism even more ancient than that of the thousand-year Reich. These bunkers became the model for the best-known of Virilio's architectural works with Claude Parent, in the firm Architecture Principe: the church of Saint Bernadette du Banlay. Make no mistake, this was a direct imitation of the forms of the Atlantic Wall, specifically of the curved observation posts which were some of the most striking of those documented in *Bunker Archaeology*. Designed in 1964, it's an incredibly puritan structure for the Catholic Church, with its bare concrete walls and an unreadable military exterior; but the interior makes Virilio's point about the spiritualisation of the bunker, in that the thin slivers of light which once came through the observation strips, originally just narrow enough to fit the tip of a machine gun, this time illuminate the church in appropriately pathetic fashion, with strips of what becomes in the crepuscular context an especially vivid light, offsetting a concrete which is left without detailing, without any obvious kind of architectural treatment. This church marks the culmination of a bizarre metamorphosis: From a utilitarian, instant architecture designed for emergency into something still, ponderous and seemingly eternal. It is especially extraordinary, then, that another more famous example of the Atlantic Wall making its way into mainstream architecture took place at the hands of architects best known for changeability, in-built obsolescence and bright, jolly optimism – the Archigram group.

MOUND AND GROUND

Archigram was a journal that ran from the early 60s to the 70s, written and edited by a group of architects, many of whom practised for the Greater London Council, and some of whom later went on to design wilfully spectacular 'blobitecture' in the 00s: Warren Chalk, Dennis Crompton, Peter Cook, David Greene, Ron Herron and Mike Webb. Archigram is usually described in terms of what Sam Jacob derisively calls '1960s grooviness: loon pants, lava lamps, men with moustaches and birds in miniskirts'. The journal, and the increasingly megalomaniacal projects featured inside it, are the antithesis of sober, sombre Brutalism – a cornucopia of bright colours and whimsical hypertechnology. The Plug-In City, The Instant City, the Walking City, the Bottery and the Electric Tomato – all of them imagining an architecture of inbuilt obsolescence, where buildings could be used and then discarded like any other consumer good, but where new networks and frameworks could provide a new mobility free from the earthbound mundanities of serious architecture. Now that we are secure in the knowledge that cities will not walk or float (something by no means certain in the late 1960s), Archigram are indulged and enjoyed as sixties 'icons' – The architectural equivalent of Terry Gilliam's animations for Monty Python or (former architectural student) Nick Mason's cover for Pink Floyd's *Relics*, their work (in the words of Sam Jacob) 'beautiful and meaningless like fantasy art. It combined traditional Victorian engineering and Heath Robinson mechanics with a naive trust in megastructures ... Architects look at this frightening vision, smile and think "how crazy, how fun!"'. The possibility that Archigram might have anything to do with something as menacing and unnerving as Nazi defensive structures would seem inconceivable.

Their built work as a collective never extended further than a playground in Milton Keynes and a swimming pool for Rod Stewart (neither of which are extant). However, in the early 1960s half of the group were the principal designers of the South Bank Complex, the Brutalist riposte to the bright, optimistic modernism of the Royal Festival Hall and the remains of the 1951 Festival of Britain. The original festival showed a celebratory, instant modernism which would seem to be a precursor to the seaside jollity of many Archigram projects; yet when the Festival site was prepared for new buildings, the plans were very different. Ron Herron, Warren Chalk and Dennis Crompton, along with John Attenborough, for group leader Norman Engleback, were the 'hairiest' of the many design groups of the Greater London Council. Their South Bank scheme, largely designed in 1960 but worked on until 1967-8, was a combination of the interest in pedestrian circulation and a certain 'anti-architectural' approach – both taken from the 'New Brutalism' of Alison and Peter Smithson – along with a windowless harshness which appears to owe a great deal to the Atlantic Wall. Brutalism was an idea developed in the 1950s by British architects and theorists which involved overturning the purist, rationalist aesthetics that informed post-war rebuilding in favour of a fragmented, impacted approach to building and planning. At first, the material with which it would become synonymous – reinforced concrete – was irrelevant, and its earliest instance, the Smithdon School in Hunstanton, was a work of steel and glass. Brutalism made an architectural fetish of services (water towers, pipes, etc), structural 'honesty' and stark, immediately memorable images – and, in planning, a focus not on towers in parkland, but on walkways, multiple levels, the famous 'streets in the sky' that ran through Brutalist housing schemes. It was an architecture based on a contradiction between designing for people, for sociability and interaction, and a stylishness based on the photogenic, imposing image. The South Bank development certainly featured plenty of walkways and public spaces – the undercroft now used by skateboarders, the many levels now partly closed to the public – but it took the image-making tendency to an extremely stark level: A dissonant, mute form where functions were unreadable from the exterior, without light or the intimation of (internal) human activity. The plan, cutely dubbed 'crumbly', actually involved exploding the usual building form, leaving it as a series of broken shards linked together by the pedestrian spaces – the 'crumbliness' seemed to refer more to the porous, tactile surfaces.

The head of the GLC architects' department, Hubert Bennett, was aghast at the Centre's extremism and added a grid of precast concrete panels in a desperate attempt to give the buildings a 'face' of some sort, leading to Herron, Chalk, Crompton and Attenborough's resignation (they were reinstated after a *Guardian* campaign). On completion the militaristic metaphors of the concrete

forms (not to mention the glass spikes atop the Hayward Gallery) were immediately noted – the review in *Casabella* lamented 'the idea is as exquisite as the deck of a battleship [...] but on closer inspection, it turns out to be rather a sad collection of Second World War bunkers'. Even its defenders have managed to find the structure threatening and redolent of the emergency architecture of the Second World War: Simon Sadler in *Archigram – Architecture*

Without Architecture compares the glinting window of the Hayward Gallery to the slit of a 'pillbox', but claims 'the aggressive imagery of a gun emplacement is tempered by reminiscences of dinosaur movies and comic books'. The latter observation brings us closer to exactly why the Art Galleries and Concert Halls of London's South Bank have such a formal kinship with the Atlantic Wall. Certainly the 'pillbox' gun emplacements constructed in 1940 in Britain lacked the strangeness and complexity of the Nazi structures, so they seem a less likely source. Archigram had always been based on a 'toys for boys' aesthetic of fabulous machines, terrible monsters and available women, one where the science fiction comics they excerpted and reproduced in the Archigram journal could easily be of a piece with World War Two adventures, their horror dissipated by time and commercialism. Nazism might have been just another source of fantastic, malevolent machines to add to the walking cities and mobile homes. There was undeniably an influence from military technology at work in Archigram's imaginary architecture. In *Archigram* 6, a special issue on the 1940s, an editorial by South Bank architect Warren Chalk noted:

> The first half of the forties saw a great inventive leap made out of necessity for survival, advancing technology and mass-production techniques and demonstrating man's ingenuity, courage and investment under the stress and pressure of war. Out of this period came a strange social idealism. The idealism was to fade, but not the technology ...

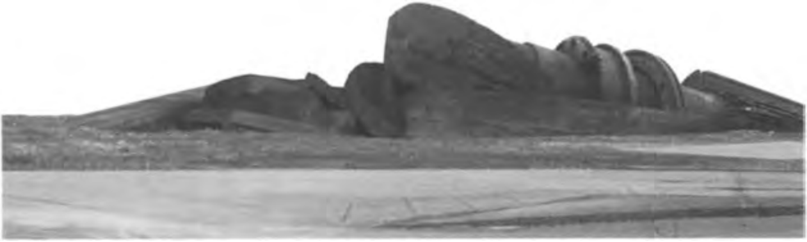
The technology Chalk was referring to was largely 'dry' types of building technique, the easily assembled 'Meccano' architecture which they were trying to continue in the '60s: 'prefabricated housing types [...] part of the 'clip-on/plug-in' heritage'. But what he says could equally be applied to the messier, 'wet' technologies of poured concrete, the heaping of which – whether by slave labourers or contractors – was the common factor in the Atlantic Wall and the South Bank Centre.

Visited today, the South Bank Centre looks distinctly odd in the context of a largely 'regenerated' riverfront. The Royal Festival Hall, into which reaches one of Chalk/Crompton/Herron/Attenborough's walkways, has been given an expensive facelift; the National Theatre which followed the SBC was cleaned up, making its relative classicism all the more clear; and a glass pavilion has been added to the Hayward Gallery. The buildings themselves are as rough as they ever were, however – the precast panels imposed on the complex appear to be rotting, and stalactites hang from the canopies and jutting extrusions; compared with the light modernism of the surrounding area, and the new buildings by Allies and Morrison, it appears ever more strange and ferocious, even down to the heavy, sculpted and weirdly organic metal doors, seemingly escaped from HR Geiger's work for *Alien.* It is in its desuetude that the anti-architectural, extremist ambitiousness of the South Bank complex truly reveals itself. The main reference to the complex in Archigram's written work is in their 1972 *Archigram Annual*, where it is included in a section entitled 'Mound, Ground, and Hidden Delights'. Here the inspiration for the scheme is claimed to be the 'Mappin Terraces', the artificial mountains of London Zoo. Rather than 'buildings', what we have here is a mound, a geological formation rather than a discrete work of architectural design – 'the aggregation of the unlike to the unlike in some amorphous, polyglot organism that is beyond single buildings, the notion of place and ground and artefacts as transient plantings'. The implosive concrete mound of the South Bank Centre seems designed not so much to be clipped on or clipped off, plugged in or unplugged, as to be abandoned to the mercies of nature, to be left as a series of crags which, as in Ballard or Virilio's descriptions of the Atlantic Wall, are ancient and primal expressions of advanced military technology. The similarity between this and Archigram's more famous projects is that they both represent an end-point of architecture. Here it secedes not to mobility or expendability, but instead to geological formations which hardly seem to have been 'designed' as such. Rather than the Instant City, this is the Instant Ruin.

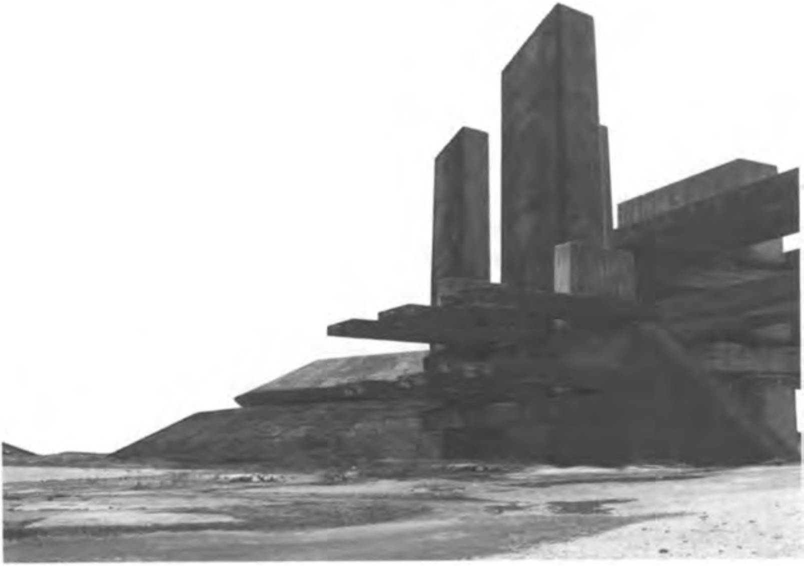
DESIGN BY DESTRUCTION

The resuscitated Modernism of the last fifteen years, though it has a certain amount in common with Archigram's positivistic, high-tech side, excises along with their utopian politics the more troubling elements of their thought. Concrete mounds become the 'sustainable design' of green roofs, walking cities are grounded, becoming PFI hospitals, and the pulp modernism of science fiction and war comics becomes an object for distant nostalgia rather than a similar attention to the apocalyptic pulp of our own time. And although it too may be an object for nostalgia, a complex such as the South Bank, with its series of fragments linked by walkways and cast in a concussive, tactile concrete, is all but unimaginable – in a building with no front or back, where would the tourists point their cameras? Accordingly, the chain of associations which links Nazi fortifications, avant-garde Catholic churches and 1960s arts centres has not continued into contemporary architecture. The fortified landscapes of the 1940s have an obvious commonality with the urban environment created by the War on Terror, whether the buffers in front of the Houses of Parliament, the concrete walls and watchtowers that divide Shia and Sunni areas of Baghdad, or the bunkers and emplacements of the Israeli Defence Force. But little of this spills over into architecture, and finds its continuation more in artistic and political speculation than in buildings.

A particularly troubling example of the former is the work of Nicholas Moulin, who creates exhilarating aestheticisations of blasted, apocalyptic landscapes. Moulin's images of paranoid cities and impossible industrial



structures are a kind of hard surrealism, a singularly unnerving re-imagining of urban space. In 2009 an exhibition of his work in Sheffield showed the inspiration of that city's Brutalist buildings, removed from their historical context and fused together, so that a windowless, militaristic structure such as the city's Electricity Substation is smashed together into the utopian socialist architecture of the Park Hill flats. Three photomontages were produced from components taken from local architecture, under the title *Wenluderwind*. Brutalist architecture was essentially optimistic, an attempt to create an open, socialist city. Yet the only other buildings in Britain to have ever employed so much reinforced concrete were pillboxes and bunkers. In Moulin's images, the difference



Nicolas Moulin, *Wenluderwind 2*, digital print, 2009. Courtesy the artist.

between these two kinds of concrete structure disappears, and the end result is a horrifying but thrilling unarchitecture made up of non-functional, barely even structural planes and fragments, thrown together to create aggressive agglomerations. While the open walkways and pedestrian levels of Brutalist buildings tried to engender community and solidarity, Moulin presents a city without people. The architectural site-spotter might recognise individual components of these compacted forms – the 'free and anonymous' planes of Victor Pasmore's Apollo Pavilion, the 'acoustic mirrors' of World War One, the walkways of Park Hill, the cast concrete patterns of Sheffield's underpasses, the obligatory bunkers – but they become irrelevant in these ferocious landscapes. Here, walkways go nowhere, blocks of flats transform into sheer, faceless walls, formerly functional components become hieratic monuments, girders are topped with spikes, objects are buried in the concrete while weeds crack the surface.

For those of us who admire the spirit of Brutalist architecture, there's something unnerving in the conflation of its pedestrian spaces with the bunkers of the Organisation Todt. The concrete of social-democratic city planning is here part of the same horrifying rubble as Nazi bunkers, or today's concrete security walls. Yet another of Moulin's works, used as the promotional photo for the exhibition, suggests why the utopian and dystopian elements in modernism can be so easily fused. This is an unaltered image of Park Hill, once one of Europe's most famous public housing estates. In the midst of a gentrification project to make it as shiny and unthreatening as any other piece of regeneration architecture, one wing of the complex has been stripped bare, leaving nothing but the concrete frame, and something intended to be teeming with life now appears to have been the victim of a bombing raid. Denuded of its function and its people, this very real structure suddenly looks like one of Moulin's paranoid fictions.

While Moulin presents an amoral view of a modern city become atavistic, there are some architects who have tried to imagine a re-use of military architecture for ends other than awed aesthetic appreciation. For instance, the project *Decolonising Architecture*, by Alessandro Petti, Sandi Hilal and Eyal Weizman, envisages the transformation of Israeli military buildings in occupied Palestine (mostly, the abandoned Oush Grab complex near Bethlehem) into a variety of different forms. A bunker becomes a bingo centre, with a watchtower used as the till, severely confusing the IDF patrol. In another proposal, the bunkers are allowed, as with Archigram's mounds and the disappearing, reclaimed bunkers documented by Virilio, to be taken over by nature. This is done for specific political reasons, in order to prevent the re-use of the structures by the Israeli army or by settlers. One idea entails part-burying them in rubble, another advocates puncturing the bunkers with holes so that they can be used for roosting by the migratory birds that converge on the hilltops. The architects call this 'design by destruction.'

Political Plastic

Interview with Eyal Weizman

In 2003, architect Eyal Weizman co-curated the exhibition A Civilian Occupation[1] *in which work by photographers. journalists and architects was combined to present a revealing account of the role of architecture in the Israeli occupation of Palestine. Censored by the Association of Israeli Architects, the exhibition demonstrated the potential of this provocative new perspective for shifting debate on the occupation from interminable moral polarisation to forensic examination.*

Cutting through the endemic euphemisms and evasions surrounding the debate on Israel/Palestine with a carefully-calibrated assemblage of theoretical analysis, interdisciplinary research and reportage, Weizman's book Hollow Land[2] *expands this project, traversing material and historical cross-sections of the occupation and its territorialities to reveal how the governance of space meshes with disturbing new modes of political and military power.*

Weizman's architectural practice with Sandi Hilal and Allesandro Petti, Decolonizing Architecture, *now proposes direct interventions into formerly colonized spaces with a view to defusing their political charge.*

In our interview with Weizman we discuss Hollow Land, Decolonizing Architecture *and his recent work which extends and develops 'forensic architecture', the evolving theoretical framework that has emerged from his research and practice.*

---

[1] See R. Segal and E. Weizman (eds.) *A Civilian Occupation: The Politics of Israeli Architecture* (London: Verso, 2003).

[2] E. Weizman *Hollow Land: Israel's Architecture of Occupation* (London: Verso, 2007).

Collapse: In *Hollow Land* you speak of two distinct senses of the word 'architecture': Firstly you demonstrate that a reading of even the apparently mundane details of architectural projects under the Israeli occupation, reveals political investments, and the use of architecture as part of an extra-military arsenal. But this materiality of architectural structures *per se* embodies, develops and sustains the novel political structures which give the second sense of 'architecture': that of the architecture of the occupation itself, the political process seen as an enterprise of architecture – the construction, partition and organisation of (geographical, municipal, domestic ...) volumes.

We have long known that in being attentive to the practices of architecture and the way that they construct space, we can shed light on aspects of political life; how would you define your distinctive theoretical approach to this problem?

Eyal Weizman: In terms of the second sense, perhaps – in a rather abstract way – it is probably best to think about this question as bearing on the relation between *forces* and *forms*. The assumption is that – although in a nondirect and complicated manner – historical events are registered in material organisation. Therefore we might be able to glean from a forensic investigation of material spaces and traces the history that produced them, that is folded into them. The question is: How are histories inscribed in spatial products? And how can we make the object 'speak' them? So this meaning of architecture is a tuning in to the complicated reciprocal relationship between forces and forms.

The term *forensics* is really important here: Forensics, from the latin source, means *in front of the forum*: it is the art and skill of speaking on behalf of objects – narrating convincing histories from objects, convincing enough to become what we call evidence – to a forum of citizens or judges. Forensics is one of the methods that allows objects (or things) to speak, or a way of listening to them. So there are in this sense two interrelated sets of spatial relations folded into the term 'forensics': one is the relation between an event (or histories) and the spaces in which it is registered, and the other is the relation between the *spatial representation* of history and the forums within which it resonates or which it creates. This forensic dimension of architecture can be understood as an act both of claim-making and forum-building.

And it is the methods for exposing this that I was concerned with in *HL*: A process of 'forensic architecture' that is different from but analogous to, say, 'forensic archaeology', where one engages in a reading of how historical processes become form, and how, therefore, forms or material organisations are diagrams of the spatial, political and military relationships within them.

'Forensic architecture' thus aspires to reconstruct and narrate undecided or controversial events through a close study of the material properties of the spatial/urban realities in which these events are registered; to turn mute spatial products into active material witnesses that can be interrogated (and cross-examined). In this sense, the 'architecture' in 'forensic architecture' designates, not the product of building design, but an expanded field of spatial investigation and enquiry. On the other hand, the adjective 'forensic' can be understood as the very condition that enables architecture to become a diagnostic technique, whereby immaterial forces are made manifest and thus proclaim themselves.

But this process is elusive and contingent. Rather than assuming any straightforward mechanical materialisation of time, or a conclusive, transparent, objective apparatus of truth claims, its reading is inclined towards complex, sometimes unstable, even contradictory, accounts of events. It's more like the murky ground of a 'fuzzy' forensics of probabilities, possibilities and interpretations.

Nevertheless, there is a very simple mechanical way to imagine this relation – and I think that the Wall is a good example, because it could be read as one of the clearest mechanical manifestations of the relation of forces to form.

C: This is the Separation Wall, which serves as an emblem for one of the fundamental contentions of *HL*: that frontiers and borders can no longer be understood as rigid cartographical boundaries separating territories in two dimensions, but must be understood in three dimensions and as elastic and dynamic. Following Danny Tirza, you describe the Wall as a 'political seismograph gone mad', registering not only state and international intervention, but also micropolitical actions.

EW: Yes, you have a construction line of fortification that is elastic, and you have the politics of the Israeli-Palestinian-international political system, on the micro and macro levels: The international community, Palestinian resistance actions, and to some degree the residents of the Wall Zone – Palestinians, represented by human rights lawyers – are all constantly pushing and pulling at the path of this line as it is being built, routing and rerouting it. So that when it 'dries out' – which is the term human rights lawyers give to its state after all conflicts have been registered in its layout

– when it 'solidifies', you can see in every twist, turn and detail of the route itself the material imprint of forces, as they are applied within a particular human and topographical terrain. Now, that's a rather clear way of imagining the relation between forms and forces, but there are many other different ways in which forces are mediated into form, in what is always a complex process, that I hope also to capture or at least to note. Whether or not it achieves it in finished form, the book sets itself the task of thinking this materialisation of time, and it sees matter not only as an imprint of relations, but as itself an agent within the conflict.

The wall is initially a media space. Walls really do not stop flows. They modulate flows across them – differentiating them: money, people, electricity, sewage, water ... it's a system of filters and modulations. And the act of crossing is also always registration, recording, etc. Ultimately, if you want to cross the wall, if you're determined to cross it, you can; there may be a delay but it can be crossed. If not I wouldn't be able to go to work, which is on the Palestinian controlled side of the wall. So its path is seismograph of political forces, and also it registers all things that pass it.

C: An actor as well as a register.

EW: Yes, the Wall is an archive in these two senses of the term: it's an archive of all movements or flows across it, and its own movement (its constant transforming path) is an archive of the formative force fields surrounding it. Because the Wall is one of the objects that registers its environment, environmental forcefield – political environment – it can read this in a forensic sense.

So, you can see the politics in things, politics as it is articulated in the relationship between processes, agents, etc. across the territory. Consequently, if we dare to look at politics as a material politics, then architectural methodology is useful to analyse it. Politics can't, of course, simply be reduced to it; but it is incredibly useful to take it seriously, in terms of that kind of forensic relation.

C: If we refrain from saying that this second sense of 'architecture' is 'more profound' it is because of your refusal to treat 'empirical' architectural details as semiotic epiphenomena, mere *representations* or *signs* of supposedly 'deeper' infrastructural determinants. This seems to provide the key to your conception of the relation between the material practices of architecture and the idea of an 'architecture of the political'. You write of the wall that 'The logic of the late occupation is not represented by but *embedded* and *saturated* within these structures. The Wall itself *reiterates* some of these built physiognomies.'[3] The two senses of architecture, therefore, are intertwined in a variety of ways, through the multiple examples of embedding, saturation, reiteration, that *HL* exposes.

EW: Each material, in each example I'm writing of, has its own characteristics with regard to the way in which it invites politics to participate in it. So on one hand you could say the Wall is equivalent to a sensitive photographic film. But not in the sense that it is a representation. Things are printed, not on it (in a symbolic politics of graffiti) but *in* it; its form is a snapshot of certain changing relations.

---

[3] *HL* 153, our emphasis.

But this has to do with the way it is constructed: the modular units which allow certain kinds of transformation, the way in which some material characteristics determine how it sits on the topography itself. So there are so many features through which politics traverses an object. Some of them are underground in the porosity of rock, the flow of water, in what kinds of plants grow on western side slopes, because the rain clouds come from the west, and drain back to the west. Ultimately, what goes into that kind of layout are so many natural, political, artificial, micropolitical forcefields, influences in which the Wall itself participates as an agent, in this kind of complex ecology of things. We must find the language to open up political process to these fields of knowledge. I find that otherwise politics is too often reduced to a kind of intentionality – you always need a culprit ... in whose mind an 'evil scheme' is emerging.

C: Then the heroic task of resistance becomes that of unveiling the ultimate centre, the face of power behind the complexity …

EW: Yes, so a lot of the time accounts of the wall are just boringly simple – Ariel Sharon drawing a line, Israel wants to do this, and so on … but they leave out everything to do with material characteristics. Also the problem of the path of the Wall has to do with the negotiation between security and agriculture: Agriculture is what forms the basis of the Israeli High Court of Justice's calculations of proportionality, i.e. the amount of wheat or olives that can acceptably be traded for security. This kind of negotiation is interesting politically, because it means that the Israeli structures are designed not according to their explicit political rhetoric, but through actual self-imposed moderations that are the only way they can achieve success. The moderation process of the occupation is more interesting than its naked application of power, because it is in this moderation that *calculations* take place: life versus security, water versus control, and, beyond these simple binaries, a whole field of calculations through which the occupation takes shape. This disturbs the simple logic of security, which is very politically determined. The minute this logic is enacted, it becomes a matter of counterbalances – all sorts of other agencies come into the picture: farmers, but also underground water, land consistency, real estate interests, community leaders, topography, environment and environmentalists, latitude, height, old graves – all these things, all these agents.

C: This vision of the multiple agencies involved seems to minimise the role of the state: its agency need no longer be central to understanding the process of colonization. Nevertheless isn't the rhetoric of naturalisation – the notion that the process is in some sense the natural outcome of multiple intersecting forces – precisely that invoked by the State to dissimulate its power behind an 'appearance of disappearance'?

EW: Yes I agree, but it's not a case of disappearance, it's more a case of the *strategic withdrawal* of the state: it appears and disappears. There's a real strong state form, constantly balancing these forces, and then acting visibly and declaring their suspension. Gaza is evacuated – we could say, it's worse, it's still occupied. Nevertheless, something has been done – Israeli settlers, by an act of state, immediately lost the right to live there, their lease on the ground was terminated. So, the power of the state is that it is withdrawn and than reappears. the interplay between chaos and order is extremely useful to it. This might be a particular feature of this colonization: the withdrawal of the state, the appearance of a 'weak state', the creation of a degree of chaos, are necessary means for having acts done outside and despite the law (international law and Israel's own) and outside state agreements and obligations. The complexity of multiple agents and the chaos of the frontier is very much manipulated by this state power. The paradox is that the state must suspend its own laws and rules so as to expand the territory, to land grab and kill, in order to create what it calls 'pacification', upon which its laws can again be applied. That is, the law has to be disregarded (not suspended) to be later enacted only when the frontier is pacified. Think about the American frontier with its genocides – which make way for the 'normal' rules of democracy to apply. This is the reciprocal relation between the frontier and the centre: the centre provides the means, the infrastructure, and when necessary the military support, and the groups are allowed to operate outside state purview.

But the frontier also demands things of the centre – politics as material reality is undertaken in the frontier. The state, which likes to think it's in control of this process, is also more or less dragged behind these processes. It imagines it can control these forces, and sometimes it can, but often the facts on the ground completely steer and shape its politics.

So this poses an historiographical problem: whether the settlement geography was planned or whether it emerged out of this interaction, without any kind of top-down planning and clear political will. This historiographical problem is similar to that of the ethnic cleansing of Palestine in '47-8. How did it happen that at the end of the war there were 750,000 Palestinians outside of state borders – by design or through a collection of contingent singularities?

These debates mirror the *historikerstreit* – the 'battle of historians' – over the Jewish genocide in Europe: To what extent was Hitler a weak dictator – Kershaw's thesis – and the beginning of extermination a process of cumulative radicalisation born out of chaos? Mommsen Bozart and Kershaw's model is that, although we imagine the Nazi state as very organised, bureaucratic, and so on, what happened was born out of bureaucratic and operational chaos: partly through the fact that that the people who could manage state affairs – the Prussian state's highly-trained bureaucrats – were replaced by the Nazis, who had no experience of government, and who started competing for the attention of Hitler; and partly through the nature of Nazi organization, which was kept deliberately overlapping, with internal conflicts and lack of clarity so that each will have a clear relation only to the top rather than laterally.

According to this model, when the killings start in 1940 in Poland, there is a level of ambiguity in the orders to the killing groups, the *Einsatzgruppe*: Each one takes initiatives, tries to outflank the other, tries to out-radicalise to get the attention of the Nazi commanders, and from within this chaos a project starts emerging, before it is fully theorised.

And the same discussion happens around the aforementioned problem of 1948: There is no question that the Zionists pushed the Palestinians, the Arabs, out of the country; the question is how this reality was created. And military historians such as Benny Morris say, in fact it starts with the battle over the roads – certain tactical necessities, some commanders needed to secure roads and didn't want people and houses by the side of the road, and they start expelling some and later they realise that people leave easily, and that they can make them leave … and then slowly that tactic is mimicked by others, until it emerges as a state project of ethnic cleansing and expulsion. On the other hand there are people like Ilan Pappe, who looks for the decision and the organisation in all this, arguing that from 1919 on there was a planned Zionist project of expulsion that was prepared in advance and carried out under orders, from the top down.

Now, the 'cumulative radicalisation' theory is nourished by functionalist approaches to history. And although I do not fully subscribe to that approach, I can see how it might be useful in describing the emergence of the elastic and ever-changing forms of the occupation. This is not to exonerate Zionism – to say that it's a kind of 'natural process' of expulsion. On the contrary. It *diffuses* responsibility, meaning that every unit or cell in the military knows exactly what to do – *without an order*, it internalises ideology, allowing every single soldier or commander to know what is expected of him *without* getting the order, or every member of settlement youth to know what to do. So that in fact, if you want to discuss it in terms of responsibility, of liability, it creates a wide diffusion. It's not a matter of separating decisions and their executors – the politics runs through the body of every soldier on the ground, the decision runs through them. So ultimately, we can think through functional analysis without making this very easy correlation between naturalisation and exoneration. When ideology operates thus, there's no need for speech. But it's not ideology in the modernist sense that we usually understand …

C: And, to go back to *HL*, what part does architecture (in the 'first sense') play in this ideological diffusion?

EW: In the organisation of space that we discussed: how does space emerge, how are the networks of settlements formed, what dictates the path of the wall … ?

Space is not a representation of a politics that would already otherwise exist in the abstract. Politics operates and flows *through* and *in* spatial practice. The architects are only part of a widely-diffused set of spatial practitioners, but without the architectural discourse and practice that was developed around the problem of building in mountain terrain, without the development of serial modes of construction, and without the complex principles that I describe in the book as 'optical urbanism', much of the aggregation of construction would not have been able to take place as it has.

C: There are however also rather straightforward examples of the ideological (in the usual sense) charge held by architecture – for instance the question of the use of nativism as an aesthetics in settlement architecture. In *HL* you describe the construction of dwellings that sustain 'national narratives of belonging',[4] with the cladding of Israeli dwellings with 'Jerusalem Stone' and the omnipresent red roofs. This indicates how strongly such imaginary 'authenticity' can (at least for those who have an investment in it) outweigh historical and geographical fact, thus allowing an architectural cosmetics to speed along the process of naturalising occupation. You emphasise the way in which, with the reducing thickness of the 'facing' required, this became increasingly admission that this was cosmetic signifier that bolstered the 'sacred identity' of 'Israeliness', retrospectively creating historical authentication and a biblically-supported sense of permanence.[5] – this being one way in which political exigencies influenced and promoted debates within Israeli architecture. Another aspect of this which you discuss is the merging of archaeology into architecture, with new buildings being supposedly only renewed expressions of a rootedness in the earth, and thus guaranteeing the discovery of a 'meaning of the earth'.[6]

---

[4] *HL*, 26.

EW: In the latter case there is a kind of literalness in which what is archaeologically preserved is extruded into a volume, and that is very much to do with a directly Heideggerian influence, or variations on Heideggerian theory, which become apparent in architectural discourse throughout the seventies and eighties; and if you think of it, it makes a lot of sense. Dwelling replaces living … meaning is brought back into the anonymous environments of modernism, national causes of 'solutions' replace housing solutions. Here a variation of this discourse comes to resolve the embarrassing paradox of Zionism: In a sense, what could be more unrooted than the early architecture of Zionism, the white boxes, the international (often mistakenly called Bauhaus) style, the kibbutz – whose construction on ubiquitous pilotis seem to hover over the surface. So much of the architecture of the colonies around Jerusalem is one of the earliest playgrounds of postmodernism worldwide.

---

[5] *HL*, 28-37.

[6] *HL*, 41-5.

Which is what brought to Palestine such luminaries as Louis Kahn and Isaiah Berlin. But I don't know if now the answer to that is a return to abstract modernism …

C: As we have discussed, you see the occupation developing less as the carrying out of a top-down Zionist state project, which would organise space according to a set of pre-given principles, and more through a selective 'laissez-faire' policy, exploiting the 'structural advantages' that chaos presents, that has allowed a multiplicity of agencies – commercial, religious, communicational, infrastructural, economic, pressure-group, legal, etc. – to produce a complex interaction, enacted in part through the organization of space, that tends to justify the processes of occupation.

Much of what you do in *HL* is to try to balance the description of the Occupied Territories as a sort of 'political plastic' which does not respond to a 'single source of power' with simultaneously trying not to yield to the temptation to vindicate this strategy of naturalisation. Can we detect here an isomorphism with Capitalism, which, as we have repeatedly seen, can hardly be combated through a head-on refusal or attack on any set of hardwired ideological principles, but employs and absorbs whatever is available, through a similar sort of 'structured chaos', until it seems there is no alternative to its 'second nature'?

EW: I would say yes – I think that, let's say, postmodern capitalism and the postmodern occupation are close relatives. We just need to historicise this: It is significant that the occupation occurs in '67 – which Chris Marker called 'the real '68' – a time of antistatism, political complexification and fragmentation, and of the introduction of new modes of technological and organisational networks. That mode of capitalism and this mode of occupation are both historical products, and being historical products, are prone to transformation. There is no eternity in any of them. There is a way in which the hysteria of the loss of any ideological alternative articulated by political power has led to this vision of capitalism as eternity – i.e. as nature, outside of history. But I don't see how this idea may survives five seconds of thinking.

C: Isn't the problem vis-à-vis capitalism rather how to overcome its *apparent* natural status and the resignation that it invites?

EW: 'Natural' is being outside history, in a way that came from nowhere, goes nowhere, will remain the same. I think that what we perceive now is a very distinct stage in the history of articulated class, labour relations, trade relations, that articulated this period in that way. There is no historical necessity in that historical product; it is political practice that can make it transform or do away with it.

C: Very well, but another aspect of this isomorphism might be as follows: You have spoken of 1967-8 as a turning point for an understanding of the occupation. How would the shifts happening in this time tie together the emergence of what we might broadly call 'postmodern' philosophy, and the movements that you track in *HL*?

EW: As I said, I agree with Chris Marker on one thing: that '67 is the real '68 – he wasn't referring to the occupation, of course, but it's true, one bleeds into the other, in all sorts of military practices and architectural styles. Part of the settlement project is initiated by Jewish communities from the States that come with a strong tradition of civil disobedience, of protest movements; and they protest against the state, they fight against this ossified labour-run state, their ideal is to break the state apart, and they do it with the zeal and some of the style of the sixties generation. Sharon is a state agent who breaks the state – the frontier man who despises state order and replaces it with action that legislates in retrospect. Sharon appears as, and behaves like, a 68er – with his raids, his kind of trip is going on unauthorised attacks to the desert, shutting off communication, killing, moving, swimming in the sea, you know, whatever, killing hostages, he's in this wild violent orgy. That's the violent face of the antistatism of the sixties and seventies.

C: He inhabits 'smooth space' …!

EW: He's one of the embodiments of '68. So again, it's not like a secondary manifestation of '68, like maybe '68 wouldn't have happened without this world … The other project that exists is third-worldism, which is broken in '67. So okay, I don't want to put Israel at the centre of everything – yes, it's Prague, we saw the tanks coming, we understood the Soviets weren't so good … but the other project – *tiermondism*, that is broken. So, you become NGOs, you become Green, this or that. But this is a moment where those histories are like engines moving each other.

You can't see that kind of face of capitalism as if it's the 'background' to the occupation, or the years of Israel of very significant prosperity at the end of the sixties, which is actually partly the motor of the transformation of the left. I'm going back to what we said at the beginning: It's not something on which it's registered, it's *part* of it, it's creating that. What collapses in '67 is not the West Bank, that's a minor story. Pan-arabism collapse with '67, and this is the loss, Nasser goes – his project is dead, America enters the Middle East and there is huge capitalization – an immediate undoing of political relations in a way that creates a hugely complex market. So again, it's not only what happened in the West Bank – the whole Middle East transformed in '67. Pan-arabism, the utopian social semi-communist nationalism that Nasser invented, was replaced with what only now becomes apparent as liberal pan-arabism, on other kinds of networks. So in effect it's a moment of cultural, economic, technological transformation, and we absolutely have to see the occupation as happening in that moment.

C: Further considering your 'forensic' approach, I wonder whether we ought to try to distinguish it from something like an imagined 'geo-psychoanalysis', aiming to excavate the unconscious material forces at work behind symptoms such as '"separation walls", "barriers", "blockades", "closures", "road blocks", "checkpoints", "sterile areas", "special security zones", "closed military areas" and "killing zones"'.[7] Chiefly because the latter might begin to sound like a species of 'psychogeography'. And indeed you begin *Hollow Land* with a quote from Patrick Keiller's *London*, a film dear to that group of writers that developed this now-popular set of ideas and practices concerning the relation of thought to place. However, the account given in *HL* seems to tell in very important ways against the tenets of this literary creed. Psychogeography often seems to suggest that merely by reconceptualising the spaces around us, by (in the words of your Keiller epigraph) 'revealing the molecular basis of [...] events', we can effect some sort of transformation – and to this extent is essentially a form of magical thinking. But even if understanding the past can help us to 'see into the future', no such kind of interpretive magic is going to transform the circumstances of the Palestinian people. What is the key to preventing psychogeographical insights from descending into a kind of literary indulgence, and transforming the results of research such as yours into pointers for concrete action in the present?

---

[7] *HL*, 6.

EW: Yes, I think the book is written very much as a polemic against this and Lefebvrian theory, which situationists and psychogeographers refer to, and which really dominates very much critical spatial and geographical discourse on Palestine. For me, the really big problem with this type of literature is that it perceives space as simultaneously too soft and too hard. It is too hard in the sense that the built realities – the work of planners and architects and builders – is solid, fixed and unchangeable. It is too soft because often it sees the possibility of agency existing in the mere literal subversion of the existing, like a de Certeau kind of walking-is-reading-is-writing ...

So you have the domain of planners, those evil guys who designed Paris top-down. Paris is always the conceptual framework with which this discourse works, and in the West Bank this makes no sense! A hard city, with planners who make straight lines, Paris as a material/political reality has dominated critical post structural discourse, but in applying the spatial theory of Paris to a dynamic frontier you miss its essence of interplay and a certain levelling of agency that operates within it. You cannot solve the problems of Paris on the hills of Palestine! ... And then you have the domain of subversion and resistance, where what is left for our citizens to do is to reimagine, to exist in a playful manner, to walk different paths, and so on. For me this is too soft, and the perception of the planners is too hard. What you do by melting them into each other, by seeing a kind of continuity, an elastic space, you basically put all action on the same level. This levelling is something very important: The Palestinian resistant, the militant, the Israeli planner, the human rights activist, the corporation – the interaction between them is very multivalented, very complex – call it a forcefield, but it is also an *interaction* that produces and reproduces space, and for this you need the constant presence of all these actors. Basically, you have to imagine a different consistency of space: rather than space that is paradoxically too hard and too soft – which can only mean resistance that ends up soft and oppression that is too hard – you need to imagine a common plane, gelatine-like, on which those forces are simultaneously existing and interacting.

Of course, this raises another problem, which we have to acknowledge, a political question: how to think resistance when it becomes one of many formative forces of the making of the spaces of the occupation, playing in this arena and according to these parameters.

Are oppositionary actions merely another formative force in the making of the realities of the occupation, and if so, how can we differentiate between this and effective, meaningful resistance?

I will give you an example of weak oppositionary action that ends up reproducing the spaces of occupation. Recently I went to meet a representative of the Quartet in Palestine. You know, the US decided it doesn't have enough power to influence Israel, so they joined with the EU, the UN and the Russians – they formed the Quartet. These are four powers that could destroy Earth four times over; and they have put Tony Blair at the head of this joint organisation. And this guy is Tony Blair's representative – he is based in the American Colony Hotel of Jerusalem, has a entire floor there. So he invited my partner and I, and we start drawing up visions, and I talk and talk, and at some point I realize that he is somewhere else – he's saying, this is all good and fine but actually … listen, what we can do now is to propose architectural plans to improve the checkpoints, to make them more comfortable. This is what he wanted to talk to us about.

C: The problem is posed exclusively in terms of amelioration.

EW: Exactly, so where is the moment of transformation? The other day the former Israeli Chief of Staff said something really derogatory about Zionist leftwing organisations and human rights groups, said they are traitors or something similar, and the current Chief of Staff said no, without these organisations there would be complete chaos! Which we can understand as meaning that the occupied areas would be ungovernable; and that therefore these groups are also part of the government of the occupation, these organisations are most important for the Israeli project … so at this point you just send back your membership card…!

C: So once you've conceptualised these agencies as interacting on the same plane, how *can* you define resistance *except* as participation in the same game?

EW: If resistance is not complete withdrawal, if it is articulated through some form of action, the question is whether there is a mode of action that might contain the possibility of a break rather than the constant elasticity of material organisation and political evolutions. This becomes a philosophical question which I can only attempt tentatively to deal with. We must think of it in terms of the question of the Lesser Evil, which is the subject of my new book.[8] I here try to engage in philosophical and theological concepts, but only insofar as they emerge spontaneously from the problem of how this interaction on the same plane can actually create a new plane, can lead to a transformation, or a phase transition – that is, something beyond the rules of the game that already exists.

C: The problem recalls the polarisation on the question of the 'event' that we find between Badiou and Deleuze: Very schematically, Badiou excludes the possibility of novelty emerging from the actualised 'situation' or state of things, since the event is precisely something that cannot be read in any of the terms of the situation, and which is drawn out through a *subjective* fidelity to a universal truth that cannot but be seen as 'impossible' in those terms. Whereas Deleuze seems to suggest that an effort made against our spontaneous acceptance of the terms of representation or actuality (the 'image of thought'), might enable one to read the 'landscape' of virtuality itself, and prospect within the infinite resource of the virtual for intense singular points or 'lines of flight' that can be actualised.

---

[8] *Il male minore* (Rome: Edizioni Nottetempo, 2009); *The Lesser Evil* (London: Verso, forthcoming 2010).

Of course, the charges which advocates of these positions make against each other are respectively, that of waiting, militating, for nothing less than a decisive miracle; and that of resigning oneself to a piecemeal re-engineering, re-formation, of the existing world.

EW: This bears a lot on the problem; if one is limited to either of these respective 'camps', it is rather clear where it places me, as it seems to me that the necessary transformative event could only emerge out of our political practice. There is thus a double problem, one of waiting for the arrival of a new political field, as the condition of a new life, the other that everything one might do would be already in the name of the occupation, because it is carried out under the occupation, in its endlessness. So we need to wait, or to pray, maybe a god can save us …

I guess one of the ways to complicate this further is to think of the idea of political action in relation to the end, which is embodied in the term that everybody uses, that of the *solution* – the two-state 'solution', the one-state 'solution'. Yes, in fact, these days the politics of Palestine – or the politics on Palestine – is indeed locked between two positions – end versus endlessness – one demanding the 'end of occupation' and the other claiming that no end is in sight and that there is a certain endlessness of conflict. This latter point of view is not about what solution to take – 'this one is *good* and this one is *not good*,' or the details of a solution, but rather about the idea of whether or not a solution is possible at all.

If a solution is not possible, this position goes, we are trapped in an 'endless present', a historical process without culmination. And without a solution we have to be able constantly to manage the conflict. The question then becomes that of finding *means of government* and the technology – much of it spatial technology – with which to manage this 'endless present' …

But we should make it clear that the search for the end was itself always part of the mechanism of the occupation. Every form that the occupation has taken since 1967 has been presented as an attempt to end the occupation. Perhaps the only constant thing about the occupation is that there are always attempts to end it. The geography of the occupation is thus physically shaped by the attempts to end the occupation, or to put it differently, to give shape – territorially, economically, and politically – to its never-ending end. We are constantly on the brink of having the occupation finished (another small push, another initiative…) and all actions on the ground (building settlements/evacuating settlements in Gaza, building outposts/removing the outposts, erecting the Wall/changing the path of the Wall) are undertaken in relation to this impending end ('why don't they let us end it?'). Each of the specific constructs that *HL* unpacks could be understood in relation to the concept of the politics of the (impending) end.

When discussing the end and looking at the ground, we tend to see yet another layer of physical apparati added to the growing piles of destruction. The occupation is finally nothing but its constant end … Therefore we need be suspicious of anyone that runs under the slogan 'end the occupation' – they must have yet another spatial apparatus in mind.

So this is how I would approach your question: It is by changing the frames of this 'end', this 'solution', replacing its terms with others, that we can give rise to another political reality and physical reality. And so, in the context of the research office I co-direct with Sandi Hilal and Alessandro Petti, what we have done is to replace that word 'solution' with a slightly old-fashioned, very banal word, but one we think is right: *decolonization*.[9] Which in fact refers to principles, to values, to a process rather than to an end-state. Decolonization doesn't mean people need to be moved from one place to another, but it rather means a system of inequalities must be undone, and the rest follows. The system in question is related to the land, to the law, to the military, to anything that's structured by colonialism.

In *Hollow Land* I presented *Decolonizing Architecture* as a chapter that deals with a project for the Palestinian ministry. Prior to the evacuation of the ground settlements in Gaza in 2005 I was part of a team speculating on different uses for these colonies/suburbs when in Palestinian hands. Issues of architecture were then at the centre of geopolitical debate, with the main question being how to understand and reuse the single family suburban home. The Americans saw its subjectivation potential, with Condoleeza Rice suggesting that its being inhabited as a suburban home by Palestinians would befit an American agenda that seeks to civilize Gaza by creating a broad-based middle class. In the end, the Israelis opted for destruction, part of the reason being the wish to deny an image of Palestinians living in homes of Jews (demonstrating a certain reversal and thus reversibility of a Zionist project otherwise typified by the opposite). In 2007, I joined together with Alessandro Petti and Sandi Hilal, with a grant from the Hodenschild Foundation, to form a new version of the project, this time on the West Bank. We decided we did not want to work with the Palestinian ministry, which since 2006 is no longer an elected body. So we formed our own organization, which is independent, and we have an office in a house in Beit Sahour, a little town just east of Bethlehem, on the edge of the desert. Initially, we had to change the way that architectural practice works – we turned the office into a residency. There are many volunteers: architects from Palestine, and internationals. And we run it also as an seminar, with readings and lectures. We hope that, and in some cases see how, our designs start to help in setting the stakes: Politicians or NGOs are using it to claim for land or to make a legal suit for various things. Architecture can become a tool in the political process.

---

[9] See the *Decolonizing Architecture* project, at http://www.decolonizing.ps/.

To explain the thinking behind this project, let's look at 'decolonization', and the other concept that might start to guide an egalitarian future in the context of Palestine: 'return' (of refugees). Every 'return' of refugees from where they have been expelled is already a return to the (over) built, a displacement from the rural that will seek a return to the urban; there is no longer a virgin landscape to return to, or else the search for the original landscape will entail horrific violence. Like 'decolonization', 'return' suggests a relation of deactivation and reversal, a relation to the past and the future simultaneously; but there is no return to what has been lost, there is only a return to the built, and this return has also an explosive potential to articulate egalitarianism when one thinks about the transformation of realities on the ground.

Therefore, by articulating our political action vis-à-vis that kind of principle, the principle of equality between Israelis and Palestinians across this area, I think this is a much better frame than talking about this state, that state, four states, or whatever. Ultimately that's not what is important. And therefore we think that there are moments of possibility in the present where one can start articulating the idea of equality, seeking to open another trajectory. And these are those moments of the real transformation of the structure of the system itself. But one needs not wait for a miracle to start acting. You show that a relatively small part of the system – say a settlement – can be liberated, even as part of a compromised political process in relation to the politics of the present; when such a colony is unplugged from the political forces that charge it – one may say that it becomes a banal suburb … whereas right now such a suburb or colony is charged with the people who live in it, travel to it, come on the roads to it, the soldiers around it, electronics, and so on. It had power – does the power that exists in the architecture of colonial exclusion remain in it like a residue, when it is unplugged? The problem is also how to use it in a way that does not reproduce, that really breaks, this relationship of power and form. So: articulated differently, inhabited differently. Not in a kind of soft way – 'let's imagine we're in a different world' – but 'how do you build something else from it that is real?'.

This action could be accused of being part of the contemporary politics of oppression, but the question is whether there could be something in excess of this order; what is this excess? What other trajectory is it possible to open by refashioning the colonies, and why is it important? We maintain that by operating with the term 'decolonization', by demonstrating the possible other life that could exist within these moments of liberation, one might open a way to operate in the present in relation to a future that is much further away than the one-state/two-state thing. So it's both immediate and very far.

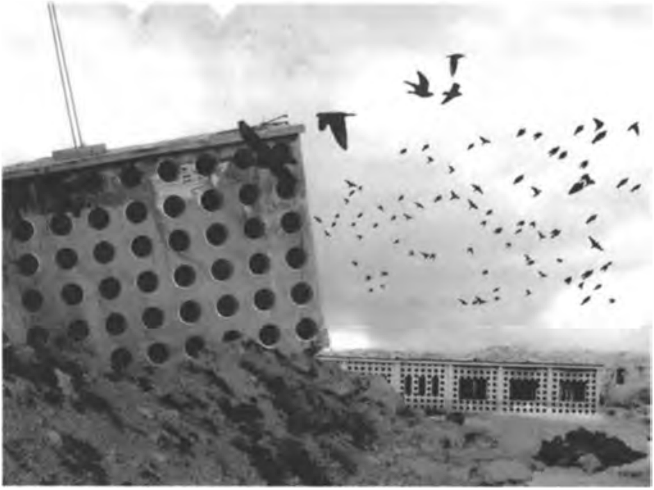
C: So the spaces despoiled by power represent an opportunity in so far as they become depotentiated in terms of the existing politics, and operate within this new political temporality. But does your speaking of 'excess' reflect a kind of materialist principle of hope (immanent, and set against both the hopelessness of the endless present and the redemptive hope of a solution): That (geographical, architectural) matter is ultimately innocent, that matter, at some level, can be decoupled from power? Isn't that a dangerous assumption? Is matter ever possessed of that kind of divine neutrality, beyond temporal political power?

EW: I like your suggestion of a materialist notion of hope. The issue is of course about the residue that is left after this unplugging. This lingering residue is different in each case, with each building and/or military base. The task is to identify this power that remains, this charge, and to attempt to reorient it.

C: The occupation seems to have continually identified geographical and topological contingencies, accentuating amplifying and exploiting them through architectural intervention. *DA* employs similar tactics, but in order to defuse colonial power.

EW: Again, I think you can say that our aim throughout the project is not to simply undo the power and techniques of the occupation but to reorient them.

For instance, we have permission from the Mayor of Beit Sahour to redesign a military base that was evacuated two years ago.[10] It is a beautiful area overlooking the town (obviously) and the desert – horrible but also beautiful. It's like a big fortress where soldiers piled earth continuously into ramparts until the top of the hill started looking like the crater of a volcano. And in there, in this place, by some



---

[10] http://www.decolonizing.ps/site/?page_id=210

fluke of nature – you know migrating birds travel through Palestine on the way from Siberia to Africa, because they all travel through what is called the Syrian African crack; it's a kind of navigation and migration route for them. And every year they return to specific hilltops. This is a fantastic spectacle of nature, where for several weeks in fall and spring you have tens, maybe hundreds of thousands of birds circulating in swarms in the air, and somehow landing on those points. One of them is this military base – the Palestinians joke that the Israelis abandoned it because of a kind of 'Hitchcock effect'! And in a sense our claim, the legal issue that we participate in because we designed that site, is not on behalf of people but on behalf of nature. We almost want to say, human rights, its claims and its regime is ridiculous here, it's too late, and anyway it's become part of the language of the occupation itself. So we use birds as the subject of rights in court, something that has rather confused the Israeli authorities. But as you know, this refers to the courts in mediaeval times where animals were standing trial. Our articulation of the idea of return here was a 'return to nature.'

C: An example of real naturalization …!

EW: Or rather, using nature politically ... We're claiming it back for nature, and designing it simply to be abandoned and used by birds. We design not for a construction but for the controlled disintegration of the building, we accelerate or intervene in the process of its disintegration: Decay as a process of form-making in architecture.

My partner Alessandro Petti is a student and a friend of Giorgio Agamben, and the later is sometimes involved in our discussions. He introduced his concept of 'profanation' as a way of thinking the deactivation of the spatial apparatus of exclusion. Sacralisation follows the spatial logic of the separation of the sacred, when a system of exclusion simply moves down from the order of the divine. If the sacred, as a spatial practice, separates and secludes things out of common use, profanation is the undoing of this process. The dismantling of the power that exists. 'To profane' signified a restoration of things to the common use. For example, one of the main interventions was in the grounds of the settlement P'sagot, where our intervention sought to transform parts of this suburban colony into a nucleus of public institutions.

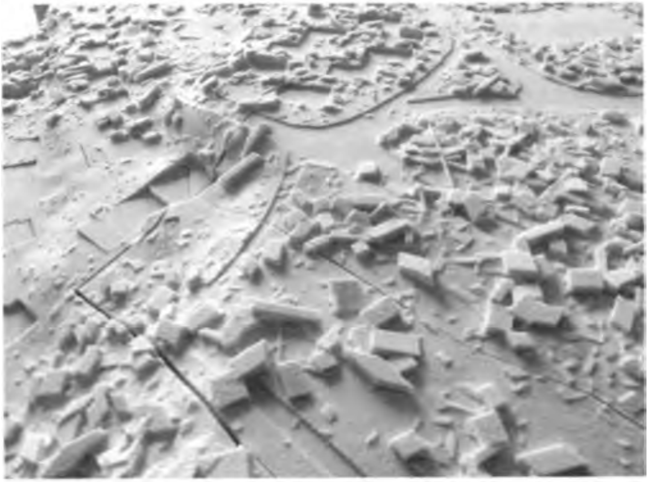
We think that at present, our task as architects must be that of transformation of the existing; and in relation to the ground, it must be articulated in relation to the question of *ungrounding*, a form of construction that creates a different gestalt, a different figure-ground relation, between construction and the landscape.

The question of ungrounding is really that the ground is a certain code, both at the operational and symbolic levels: the code of the city – its operational logic and its ideology is in the first fifteen centimetres. We are not concerned with the changing of the buildings themselves. Architecture has dealt successfully with the problem of this transformation – we know since the sixties that every structure is adaptable to any use – the question that remains, however, is that of the surface itself. It is a 'thick surface' in which occurs the designation of private and public, walk/drive/no walk, the relation between figure and ground, between the object and the surface on which it relies. So that is the challenge architecture is facing. And this is where *DA* intervenes.

C: When you come to rebuild these first five centimeters, what models do you rely on to avoid simply creating new problems by unilaterally imposing a new 'plan'? Which agencies would be involved in the re-territorialisation?

EW: In some parts of the areas we deal with, the regrounding is undertaken in a way that allows for multiple uses. We called it – with situ studio in New York – a 'smart surface' – a single ground surface area that could be used for driving, walking, growing. This is achieved by a variable density of paving elements produced from rubble.

C: This is interesting in relation to the philosophical discourse on the search for grounds, the Kantian task of properly grounding philosophy, followed by Nietzsche and others' repudiation of this architectonic ambition.



Reversing Kant's use of ground as a metaphor for philosophical security, could we could say that it is in fact, this very concrete sense, the ground – the 'first five centimetres' – that furnishes us with certain – political, social – certainties?

EW: Yes, as I mentioned before, the city is not spatially governed so much by its structures and buildings but rather by the way it organises and divides the surface. This is why is it essential to seek transformation not only in the buildings but rather in the ground itself; ungrounding is a certain 'liberation', we feel, from the prescribed order of planning – at least part of it …

C: A key to the nature of the strategy of the occupation is given in one of the epigraphs to *HL*, where Mourid Barghouti speaks of 'the duality of intelligence and stupidity'. This is a proposition with a double-sense, it describes a double obfuscation: You note throughout *HL* that the use of sophisticated theory has been a camouflage acting to evade responsibility for what are, at base, brutal and murderous processes – so that complexity provides cover for stupidity; at the same time, a wilful strategic stupidity and slowness in reacting has also proved useful for allowing irreversible processes to become 'locked-in' which then must be retrospectively recognised (naturalisation). These things take place through very complex processes but, as you show, these processes are quite amenable to a theoretical analysis: so here again, the status of theory is ambivalent – the insufficiency of thought is professed at in order to resist a theoretical purchase on the complex reality of the situation, but theory is used where convenient to provide a sophisticated façade for brutal actions on the ground. Was the application of 'postmodern theory' by the Israeli military ever more than an alibi?

EW: I don't think this question of theory is particular to the military. The people who most often apply theory, at least around me, are artists and architects. And I think sometimes theory does open up new sensibilities, without being translated literally. But theory, in the context of your question, belongs to a shift in sensibility; and military practice and theory produce, they go on producing – in an oblique way, they move in relation to each other. Along with the technological possibilities that were opening up, and the organisational innovations, there were philosophical innovations coming from other sources – early network culture for example. So they find echoes in each other, one language gives rise to a term that starts reorganising things in another system, but usually according to the latter's inner necessities and dynamics. So I think the answer is not to say, this or that manoeuvre is 'rhizomatic' – and that because military academies read about 'smooth space', they started walking through walls – but rather that the necessity to walk though walls, arriving out of military developments, finds the language with which it can be articulated, explained, and thus extended.

Incidentally, I thought I had found the first manuscript about walking through walls in a nineteenth-century military manual of counter-revolutionary practices, but a colleague showed me recently that in Roman siege manuals, this system already existed – In fact, it's a natural thing to do if you're a solider and you're moving through the city. But obviously, what I think happened in this case is, the question was how you co-ordinate thousands of people that are walking through the solid bulk of the city. To do this you need technology, not just theory; but to *imagine* that possibility is a leap.

On the other hand, I write in *HL* that the language of theory was not necessarily used against the Palestinians, but was used in the internal conflicts of the military itself – that some groups within the military created a language that helped them to define a common interest group within the military hierarchy, which then moved into a prominent position, with its disciples being promoted and gaining power; and then fell – just like in academia: It's an organisation – an organisation that kills; but with a similar 'sociology' to any other organisation.

C: Nevertheless, theory was used to sanitise, to bolster the illusion of precision and sophistication.

EW: Of course. In a sense what is otherwise a brutal act against indefensible people, part of the mechanism of oppression, becomes a 'sexy', cool thing. But this is not all that is at stake. I did not appreciate to what degree that article would have an effect in Israel. The officer – Aviv Kokhavi – who was talking about 'the room is your interpretation'[11] threatened to sue myself and the journal that was to publish a translation of this chapter. He cited three alleged mistakes in the article, he took on the biggest law firm in Israel – the one the deals with libel issues for the Haaretz Daily – that the military could afford him, asking that we remove his name from the article. I really wanted to go to court, because I would have liked to have 'interviewed' him again in this context, on issues – the events of that morning – whose exposure might contribute to a better understanding of the history of the occupation. So I wanted to go ahead, but he finally backed off.

---

[11] See *HL*, Chapter 7.

Now, his demand was that I take *his name* out, and the editor of the journal – a very important journal in Israel, *Theory and Criticism* – who wanted to publish the piece suggested we might take the name out, and even that it would be better for the critique if the name were not mentioned. But here we realised something very important: although there's an existing group of very good academics and writers, a structural analysis, or a post-humanistic attitude still prevails, where individuals and individual responsibility don't matter, where names are not mentioned. So that in fact you can say practically anything 'radical' in academic organs without censorship, but the problem starts when you marry a kind of investigatory journalism with theory. You can find many theoretical writings on the occupation that mention hardly any names! My work, I think, has these two machines in them, journalism and theory, and I name names.

So this started a whole debate about how to write theory into a political event, as a resistance. When one writes into the event and when one investigates a particular scenario, one must write about people that are still acting, about a crime at the moment it is undertaken, exposing and analysing simultaneously. In this sense, libel suits are in fact the indication as to the effect that this writing is having – nobody cares when you write against 'Zionism' in general, but naming names and places and units and actions intervenes within the system itself.

However, whereas newspapers, obviously, have the means to defend against libel suits, academic journals do not. So we must find new platforms and new ways of writing or ways to secure the legal backing to allow us to write the way that is necessary; otherwise we'd always be put off by the threat of libel. We need to change the way of writing criticism into the event, and for that you need to combine a certain journalistic forensics with theory; to do it differently, you need a different technology of writing opposition. There needs to be an invention of a different way of doing things. Who needs this journal, if they can't take the risk, if they back down at any threat.

C: There's perhaps the illusion that theory can 'intervene' without taking any of the risk that's involved.

EW: Yes, speaking to other academics we are rather immune. We must face the risks, and this involves all sorts of state retaliation and also of course the financial risk of libel. At first, I was willing to go and represent myself, but the journal said, we are also cited on the legal suit, so we have a lot to lose. It's the journalism *plus* the theoretical frame that did it, it was the journalism *in* the theory, and this is what I think is important, that there is something that moves the theory along with it, and it does two different kinds of work simultaneously.

C: In order to be effective and transformative theory needs to rethink the relation between the abstract and the singular – actually-existing objects and people – it's not enough to position 'theory' on a higher plane, leaving it to 'the reader' to apply it themselves.

EW: Yes, it leaves open questions – critical work sometimes tends to assume another convinced agency that will be called to action, rather than taking the action itself.

C: You suggest that even if Israel/Palestine presents us with 'a unique type of political space',[12] nevertheless '[t]he architecture of Israeli occupation could [...] be seen as an accelerator and an acceleration of other global political processes, a worst-case scenario of capitalist globalization and its spatial fall-out'.[13] As you write: 'Exported globally [...] Israeli practices and technologies have connected the uniqueness of the conflict with worldwide predilections to address security anxieties through "circulation management"'[14] Not forgetting, of course, that the situation in Israel/Palestine has had a premier role in stimulating the events at created this climate of fear in the first place. Could you pick apart for us these two terms – accelerat*or* and acceler*ation*: In what ways can the occupation be read as an augury for our future, and in what ways has it materially contributed to actually effecting and accelerating that future?

EW: It's now an established dogma to say that Israel/Palestine is a laboratory for weapons, technologies of population control, software wars, and so on. But the question is *how* does it proliferate: How is it that we've seen bits that look like the Wall in Iraq – exactly the same section – and similarly with checkpoints, etc.

---

[12] *HL*, 15.

[13] *HL*, 9-10.

[14] *HL*, 154.

Does a company go out there and sell it? Not always, or not exactly. Sometimes there is a direct transfer, a corporate or military transfer. But most often, actors in distinct places all draw from a single pool of images that exist through the media. Israel/Palestine is, in bytes per square metre or words per square meter, one of the densest places in the world. It has become a formation of the global consciousness. And very often, security officers and resistance borrow through mimicry – it's not necessarily that he was trained by an Israeli, he just exists in the same culture of which those images are part, and which they form. And then again there are other institutional ecologies, in which various levels of relations and ideas are exchanged; ecologies in which the Israeli military is only one of the nodes.

Now what I realised recently, in the next piece that I wrote, 'Legislative Attack',[15] is that the important laboratory here is not necessarily the technological development of weapons, how to kill, how to attack. There's a much more important front where intervention is meaningful and influential. And that is intervention on the level that affects our *perception of what is tolerable*, what is acceptable. And I think from one conflict to another, we push it, it's an elastic line. There is an elastic line that is constantly being drawn with every action undertaken, the line between what is and is not tolerable, what we will tolerate being done to *other* people. The momentary state of (also elastic) International Law is a diagram of the tolerable in this context. I feel that the Gaza attack is now redefining these limits. And the question is really how Israeli attacks themselves legislate laws in space. In a sense violence directed at a gray area of the law shifts the elastic limits of the law, so violence itself legislates. Given an undecided legal issue, if it can be attacked with enough guns, you produce a precedent that might shift the terms of the law. So the violence is directed simultaneously against the Palestinians and against the law. And I think that this is the most significant aspect of the 'laboratory'. People now can tolerate a situation where one state puts barbed wire around a million and a half people and counts the calories in food trucks as they enter and exit, arguing about how many calories a Palestinian man needs and therefore how much potatoes, rice, milk they should let in – basing this on the very minimum that would account for them staying alive. So this is the laboratory. It's like the Milgram experiment, where they asked people to send an electric shock – How much pain do you allow yourself to inflict? How much will be still tolerable – not by the victims, of course, but by others who are watching.

---

[15] At http://www.opendemocracy.net/article/legislative-attack.

C: The law conceived as a drawing of the line gives way to something more like the Wall; International Law can be pushed and pulled by the same forces and events that shape the Wall.

EW: Yes, it belongs to the same elasticity that is the hallmark of this occupation.

C: And you take up this question of the 'tolerable' in *The Lesser Evil*, where you discuss the transformation of political questions into matters of accounting in which the justification offered for actions is not intrinsic, but appeals to a 'calculus of harm' in which, a quantitative line having been drawn as to what is 'unacceptable', anything one notch below this (which you satirically symbolize with the number '665', just one short of 666 ...) becomes, given the supposed constraints of the situation, unquestioningly accepted.

EW: In *LE*, I'm much more interested in the very techniques of forensics itself. Here, the relationship between space and law – what constitutes an evidence, how in the last few years a transformation has occurred by which evidence takes a central place, turning into what might be called a material witness – will be unpacked through very detailed and intense case studies. And all this around the background discussion of the moderation of harm.

Addressing the notion and dilemmas of the Lesser Evil emerges out of a set of problems encountered in *HL*. As we discussed at the start of our conversation, *HL* developed a distinct spatial imaginary in which, via the category of elasticity, space is understood as a 'political plastic' – the sum total of forces that operate on and within it – which forces could thus, to some extent, be read by examining it. But within these fields of conflicts, there grew another powerful agency. Besides the military and other state agencies, the wider field of contemporary conflicts includes corporations, the media and, significantly, independent organisations and humanitarian and human rights NGOs. So the immediate question is: What is their role in the production and maintenance of the spaces of colonisation and their mechanisms of control? Furthermore, this was a personal question, since my own work was produced through interaction with various agents within this conflict, including an (already rather cautious) engagement with the human rights organization B'tselem. So a discussion about the notion of the moderation of harm, through the culture of human rights and humanitarianism, was in place. Some theoretical propositions on this issue that were only outlined in *Hollow Land*, and some relatively marginal characters in the spatial drama it unpacked, have been expanded in *LE*. These issues and characters have stepped forward to take centre stage. It is as if the footnotes of a previous work have climbed above the line, to make a new book.

This idiom of the Lesser Evil captures much that goes beyond the issue of human rights and humanitarianism; but for them the idiom functions as a sort of vernacular. It seemed to me that, as a form of political expression, the Lesser Evil has become so deeply naturalised in political speech and culture that it seems to occupy the place previously reserved for the term 'good'. The problem of the Lesser Evil is famously concerned with a necessity for a choice of action in situations where the available options are or *seem to be* limited. The condition by which this choice is articulated affirms an economic model embedded at the heart of ethics – one according to which various form of misfortune can be calculated as if they were mathematical algorithms, evaluated, and acted upon. The problem of the Lesser Evil presents a closed economy, in which one cannot question the system that produces and distributed its evils – it's a system that presents itself as one with no outside. Under its aegis, politics appears as a mathematical minimum problem: how to reduce to minimum the 'evils' generated as the collateral effect of 'necessary' actions.

Of course, the problem of the Lesser Evil has its origin in the classical philosophy of ethics and in early Christian theology. In the latter the problem was articulated through the concept of the 'tolerated sin'. But the question still casts a long shadow on the politics of the present. Recently, it has been continually invoked in the state's effort to govern the economics of violence in the context of the 'War on Terror', and in private organisations' attempt to manouevre through the paradoxes and complicities of opposition action and humanitarian aid.

C: How do these developments relate back to the spatial and architectural concerns of *HL*?

EW: Within these fields, the politics and culture of the Lesser Evil has engendered its own technologies. These 'technologies of lesser evil' are technologies with a distinct spatial dimension, an 'architecture' – that is articulated in the mobilisation and production of new types of spaces, spatial apparatuses and means of spatial analysis.

C: And how has your methodology developed from *HL* to *LE*?

EW: In *LE* I seek to investigate the politics, ideology and culture of the Lesser Evil, both theoretically and empirically, through micro-scale intense forensic probes of three controversies, each of which is also a spatial controversy. Each is concerned with a specific spatial apparatus, technique, or a set of spatial problems, where humanitarian and military logics intersect; and each is narrated through a protagonist (the relief camp as a media space in 'Arendt in Ethiopia', the topographical model as an architectural/legal representation through which a certain legal/spatial interaction takes place in 'Best of all Possible Walls', and the question of the forensics of rubble in 'Only The Criminal can Solve the Crime').

C: These 'protagonists' recall what you were saying about the importance of the embeddedness of journalism within theory, and the importance of 'naming names'. The use of 'protagonists' seems to take this a step further; the purchase of theoretical concepts on the real is secured by their demonstrable 'incorporation' into actual people.

EW: Yes, the new work takes the idea of embodied theory further I hope: three controversies that are each a moment of changing practices around the problems of the Lesser Evil. Perhaps the most interesting one concerns Marc Garlasco, who is Human Rights Watch's 'Expert on Battle Damage Assessment' – their forensic analyst.

His work demonstrates a certain transformation of the methodologies of Human Rights thinking: A shift from a close reliance on survivors to material forensics, a shift from empathy to science. As you know, empathy or testimony were the main trademarks of HR work as this suited an ideology that sought to position individual versus state.

What Garlasco does is to try and read a certain system or order in the chaos of destruction. He is looking at ruins, discussed their form, looking at ways of destruction; he tries to differentiate between bulldozer destruction and controlled blast by engineers, aerial attack, tank fire. He says "I needed to paste together the battle story … to recreate the chaos of 'battle' minute by minute ...".

Now, Garlasco mentioned to me, in full frankness, that "when hiring me in 2003 [HRW] must have known that I was already involved in the killing of about 250 civilians in Iraq." Because before joining HRW as military analyst, Garlasco worked for seven years at the Pentagon. During the Iraq War in 2003 he became 'Chief of High-Value Targeting', which essentially meant he was a military target assassin – for instance, in charge of killing Saddam Hussein and his leadership! A central part of planning these missions was to do with a calculus known as 'Collateral Damage Estimate', which establishes the 'right balance of civilian casualties in relations to the military value of a mission'. "The magic number was thirty," Garlasco explained to me when I met him. "That means that if the computer came up with thirty anticipated civilians killed, the air-strike had to go to Rumsfeld or Bush personally to sign off. Anything less than thirty could simply go ahead." This estimation of civilian deaths was done using software called *Bug Splat*, that synthesised environmental factors such as the size of the building, its construction materials and techniques, the percentage of steel and glass in its envelope, the population density within and around it (varying according to the time of day), weather condition, and so on. These were calculated against factors such as the size and type of the bomb, its fuse and the direction of the attack. So, Garlasco had to study architecture, structural-engineering, and urbanism; the killings he planned were to be undertaken in people's homes. If the aim is to use the minimum sized bomb to achieve the required effect, designing a bombing mission resembles a mathematical minimum problem. Such calculations are part of the very logic of this weapon – a weapon that hits *and* legitimises, a weapon that kills legally.

Garlasco stayed in the war although he didn't agree with it: "Whether you agree with the aim of war or not it is going to happen," he said, "so I wanted to do it in the best way I could … I had a responsibility to the pilots and the civilians." *Responsibility towards the civilians!* "I didn't try to kill civilians," he continues, "I focused on military targets and tried my very best every day to minimise civilian casualties – as required by the Geneva Convention." The question is, of course: Minimised in relation to what? Reduced from what number?

After Baghdad fell, Garlasco left the Pentagon to take the job with HRW. HRW was the organisation that sent him to Iraq for the first time. He had previously only seen the place on military screens. Garlasco's credibility as a former Pentagon expert was used extensively in its press releases and the media, where he was often referred to as 'former Pentagon officer'. And he has become the celebrity HR analyst. He has also been an extremely effective one: in Iraq, on torture, he helped McCain on the anti-torture regulations; he was in Lebanon during Israel's attack, in Georgia during the Russian one, in Afghanistan again and again; his work lead to UN to ratify the agreement on cluster bomb ban.

Now, paradoxically or not, it was his military past that gained him the visibility and credibility he enjoyed as a HR analyst. The Washington Post called him 'the man on both sides of the air war debate' and he was often asked about 'crossing the lines'. *But did Garlasco really cross any lines?* This metaphor might be misleading. Although Garlasco's move from the Pentagon to a human rights organisation was understood by many according to the popular narrative models of a 'redemption story' – like a St. Paul whose sainthood is only as great as his sin – this misses the extent to which, at present, humanitarians and militaries are intertwined in their methods and aims.

Perhaps a better model to consider is the detective genre: like Professor Moriarty in Sherlock Holmes or Dr. Hannibal Lecter – the psychotic killer in whose mind lies the clue to solving and stopping ruthless murders. A genre in which a crime can only be solved by those that can think like criminals, by those that have been criminals.

This was reflected also in his forensic works: the collapse of buildings was the method by which he planned the assassination of the Iraqi leadership, and buildings rubble was also the means by which he would reconstruct the story of an attack for HRW. As he said to me, "my forensics is a reverse engineering of the process of military destruction".

C: With this example of 'embodied theory' it seems we are close to the state of affairs Deleuze described in suggesting that a book of philosophy should be 'like a detective story' (perhaps, in view of your forensic approach, *CSI: Jerusalem!*); and that your protagonists are something like the 'conceptual personae' who, he insisted, inhabit the 'theatre of philosophy' and are necessary to the very functioning of conceptual thought. Only in the theatre of twenty-first century warfare, the dramatis personae are real people who are the avatars of stranger conceptual formations than could be invented by any philosopher, and who reveal the sometimes grotesque structural assumptions within which this warfare is carried out.

EW: But wait, there is more to the story … Finally, although his work has really transformed the capabilities of HRW, on September 15 2009, the very same day of the release of the Goldstone report, HRW announced Garlasco's suspension. A few days earlier some pro-Israel blogs publicised that

Garlasco collected Nazi-era memorabilia, and accused him of fetishism. Garlasco explained amongst other things that his geeky fascination with militaria (his fetish) only substantiates the fact he is a good forensic analyst. And I think he is right – that forensics is itself a kind of fetish – Fetish not in a Marxist or psychoanalytical sense, but in the sense that reading the event from an object always involves the excess that is within the object. The personal story of Garlasco stands behind the power of his forensics ...

C: Finally, in the postscript to *HL*, you ask how architecture as a professional practice can be expected to 'learn from' Israel/Palestine. Do you see any indications that architecture, in general, is beginning to take its political responsibility seriously – everywhere, not just in highly-heated zones such as Israel/Palestine?

EW: This is an architectural reference, of course – *Learning from Las Vegas*. So it's this moment of postmodernism where architecture needs to break the disciplinary barriers and learn from other things. But yes: I don't say it's because of this book, but there is increased involvement of architects in territorial-political issues, yes. I don't know if that's a good thing yet …

C: If Las Vegas (as well as being the original location for *CSI*) is the theme park of late capitalism, is Israel/Palestine the darkside Las Vegas … ?

EW: Interesting, Maybe the light side! The new Las Vegas …

North American astronomer and mathematician Nathaniel Bowditch correlated the letters of the alphabet with the twenty-four timezones dividing the terrestrial globe. In ‘The New American Practical Navigator’, published in 1802, he associated the letters A to M with the timezones situated east of the Greenwich Meridian, and N to Y with the timezones to the west. The zone corresponding to the 180° meridian, through which the international dateline passes, is shared between the letters M and Y, so as to indicate the same hour one day apart. The letter Z, attributed to the Greenwich timezone, the 0° meridian, gave its name to the system, known as Zulu Time, in reference to the phonetic alphabet used in radio transmissions.

Introduction to SIMADology: *Polemos* in the 21st Century

Manabrata Guha

> *... a fine enough mesh, at some epsilon, can catch anything ...*
> Martin Libicki, *The Mesh and the Net*[1]
>
> *War is not a theatre, you infidels ...*
> Abdu-Salam Faraj, *Jihad: The Absent Obligation*[2]
>
> *... Terror is not a means of imposing decision upon the enemy; it is the decision we wish to impose upon him ...*
> Brig. S. K. Malik, *The Quranic Concept of War* (1979)[3]

INTRODUCTION

Clausewitz is accorded the honour of being the pre-eminent theorist of war for, with him, the project of theorising war was so comprehensively enframed that what has since followed have been mere footnotes – the addition of details – that only serve to fill in the gaps that Clausewitz's theory did not address. But this reification of the paradigmatic Clausewitzian theory of war also carries with it the implication that the regime of thought that guides our current theorisations on and of war is an archaic one. It is archaic not because one can trace its genealogy to at least the Age of Enlightenment, but because, in effect, its evolution had already come to an end with Clausewitz' pioneering theorisation of war.[4] In more recent times, this state of affairs has been reiterated in a positive light, with the assertion that, while the character of war may change over time, the principles of war are eternal.

---

[1] M. Libicki, *The Mesh and the Net: Speculations on Armed Conflict in a Time of Free Silicon* (Washington, DC: National Defence University), 30-1.

[2] A.-S. Faraj, *Jihad: The Absent Obligation*. Quoted in Reza Negarestani's 'The Militarization of Peace: Absence of Terror or Terror of Absence?', **COLLAPSE** I, 53-91: 60.

[3] Brig. S. K. Malik, *The Quranic Concept of War* (Dehra Dun: Natraj Publishers, 1999), 59.

Thus, when questions are posed such as: Are developments in the emerging fields of Information and Communication Technologies and the 'new sciences' rendering the Clausewitzian regime of thought irrelevant? Are the growing experiences in the emerging net-centric battlespace rendering the Clausewitzian depictions of war and combat unrecognisable? Has the so-called Global War on Terror(ism) (GWOT) fractured, irreparably, the Clausewitzian paradigm of war?, more often than not, they are dismissed without a second thought.[5] The principal reason for such a summary dismissal is that, for the most part, they are regarded as fanciful speculations that not only run against the grain of the study of war and its conduct, but also against the fundamental principles that underwrite our conceptualisation and understanding of International Relations and of what it means 'to be political'. But there is no avoiding the fact that such questions are being asked and such doubts are being expressed. These are indicative of the growing uneasiness in some quarters that the integrity of the Clausewitzian theory of war may be increasingly becoming suspect not simply because the character of war has changed, but because, increasingly, our understanding of war, indeed our very imagination of war, is being shaken to its core, and is falling short of our experiences of war.[6]

---

[4] See M. Guha, *Re-Imagining War in the 21st Century: From Clausewitz to Network-centric War* (London: Routledge, forthcoming 2010).

[5] See, for example, C. Gray, *Modern Strategy* (Oxford: OUP, 1999) and *Another Bloody Century: Future War* (London: Weidenfeld & Nicholson, 2005), who suggests that nothing like this is likely to occur; C. Coker, *Future of War* (Oxford: Blackwell Publishing, 2004) and R. Leonard, *Principles of War in the Information Age* (New York, NY: Presido Press, 1998), who implicitly and, at other times, explicitly question the continuing relevance of the Clausewitzian paradigm.

Our cue for this essay is taken from a recent assertion made in the context of 'surprise and terrorism', which states that '[s]urprise is only one tactical principle of the terrorist operation but it is nonetheless an essential one. Without it, terrorism would not only be foolishly impractical as a method, but virtually inconceivable as a strategy'.[7] This is an example of how the insistence on employing the well-worn analytical framework of the Clausewitzian martial architectonic to enframe the so-called 'problem of terrorism' leads to a tragic misreading of the emerging turbulent martial landscape. Our central concern in this essay is with the revitalised, and in many ways '(re)new(ed)', emergence of the 'terror-operation' which, to put the matter plainly, has not only cast a corrosive shadow over the Clausewitzian theory of war, but has also allowed us a rare glimpse into a very strange and little-understood battlespace. In keeping with this, given that the current and emergent global security ecology is being increasingly enframed within the context of the GWOT and/or in terms of hyper-violent planetary-scale insurgencies, the *principle* of operations that are invoked to address the problematic of the 'terror-operation', particularly in the wake of the events of 9/11, is called into question. In this way, we draw attention to how the regime of thought that governs the understanding and imagination of war bequeathed to us by Clausewitz – that of a collection of battles tethered within a 'political space' – may be seen to have reached its ideational limit.

---

[6] See, for example, Arquilla and Ronfeldt, *In Athena's Camp: Preparing for Conflict in the Information Age* (Santa Monica: RAND, National Defence Research Institute, 1997). See also Leonard, *Principles of War in the Information Age.*

[7] Morris, 'Surprise and Terror: A Conceptual Framework', in *The Journal of Strategic Studies*, Vol. 32, No. 1, 1–27, February 2009, 6.

As an alternative, it is suggested that if we can indeed continue to talk about war and its conduct in the twenty-first century, then perhaps the discussion should be reconstructed in terms of a *polemos* – organised around four protocols – which manifests itself as a violent and searing rash of virally-proliferating clusters of intensive eruptions, ruptures and lesions that irreparably wreck the dominant spatio-temporal and ideational paradigms within which the State's monopoly over the exercise of organised violence has traditionally found its subjective affirmation. This emergent condition, which necessitates a different regime of thought when thinking 'war', we further argue, entails thinking of – and in terms of – alternate modes of martial operabilities – *pure tacticities* – which are mechano-in-organic insinuations of terror, surprise and havoc which, while seemingly event-specific, remain indifferent to, but complicit with/in, the very medium in which they are actuated.[8] The emergent embodiment of such insinuations is the SIMAD – a Singularly Intensive Mobile Agencity of Decay – whose primary counter-tactical principle of operation is 'hypercamouflage'.[9] We will have occasion to discuss the outlines of this counter-tactical principle and the implications that its operationalisation has for our state-centric war-machines.

---

[8] Thanks to Reza Negarestani for first suggesting the 'mechano-in-organic' formulation (email exchange).

[9] For a detailed account of 'hypercamouflage' see Negarestani, 'Militarization of Peace'. The acronym SIMAD appears in the work of the futurologist Jerome Glenn.

As we will see, the encounter with the SIMAD takes place in an *intermezzo* – a counter-intuitive and unfamiliar battlespace wherein the standard geo-political map is contorted out of recognition by an always emergent geo-philosophical diagram which, by being radically open to the attractive and densifying magneto-gravitational forces of the Earth, does not adhere to Nietzsche's weightless affirmation of 'being true to the Earth'.[10] Contrarily, such a geo-philosophical diagram plunges headlong into the flows and counter-flows of the earth's forces, thereby stretching them to the edges of their conceptual envelope by 'sounding' the depths of the Earth's surface on which fragile onto-political structures – geophysical and geopolitical edifices – rest. In this sense, the emerging battlespace – the *intermezzo* where/in we make contact with the SIMAD – is a locale in which an ungrounding of the Earth is in process and, as such, is a vertiginous soft spot on the surface of the Earth. In this battlespace, onto-privileges that sustain the traditional geopolitical difference-engines[11] through the logic of their presence corrode, decay and collapse, leading to terrifying

---

For Glenn, the acronym stands for Single Individual Massively Destructive. See J. C. Glenn and T. Gordon, *2007: The State of the Future* (NY: World Federation of UN Associations, 2007), 80.

[10] *Intermezzo* means an 'in-between'. In music, particularly in operatic music, it is a 'filler' that fills the space between two acts. In chess, 'intermezzo' is better known by the German word, 'zwischenzug', which is translated as an 'intermediate move' that a player makes in lieu of an expected move, after playing which the expected move is made. This generally results in disorienting the opponent, and is geared to create the conditions for dominating the board.

[11] State Actors, Non-State Actions, Actor-Networks, friends, enemies, allies and levels of analysis are illustrative examples of what I refer to as 'traditional geopolitical difference-engines'.

'envoidings' that fracture, weaken, and turn into sludge the material consistency of the conventional battlespace.

Of course, the 'canon' of military thought asserts that there exists an inextricable relation between thinking (strategically *on* war) and the earth (or alternatively, the coding of territory); this is a central, indeed defining, feature of the Clausewitzian theory of war, say, since the seventeenth century. We will see how the SIMAD distorts, twists and undoes this specific relation between thinking and earth/coding in geo-logical terms. In such cases, even the Deleuze-Guattarian 'nomadic war-machine' fails to gain traction. 'Territory' and the earth become 'slime', which defies the efforts of the post-modern military – a rabidly becoming-out-of-control war-machine that was originally captured and re-deployed as a pliable instrument of the State – to cast its striating and strategising net-centric grids in a bid to establish an era of 'terrifying peace'. This calls for a different way to think about war, thereby signalling the advent of the SIMAD's *polemos*.

I. FRACTURED FRAMEWORKS/ DISTORTED ANALYSES

INSIDE/OUTSIDE THE CLAUSEWITZIAN LEGACY

When Clausewitz wrote his *magnum opus*, he openly registered his desire to write a treatise on war that would serve a dual purpose. Firstly, he wanted to establish a theoretical ground for the study and analysis of war which would 'not be forgotten after two or three years, and that possibly might be picked up more than once by those who are interested in the subject';[12] and secondly, he wanted to 'bring about a revolution in the theory of war'.[13] It is worth noting that on both these counts Clausewitz was largely successful. But the import of Clausewitz's efforts, while long recognised and much appreciated, remains undervalued. This is principally because we fail fully to appreciate what the Clausewitzian theory of war aims to *defend* and instead focus on that which it tries to *explicate*. In other words, to fully register the import of Clausewitz's theoretical efforts, it is necessary to recognise that Clausewitz, quite early in his theoretical exercise, was fully cognisant with the disjunction of thought when considered in the context of war, which he identified as 'chaos on the battlefield'. It is for this reason that we are led to suggest that Clausewitz's principal theoretical and philosophical effort to create and sustain a 'theory of war' was a defensive gesture against this state of affairs. To appreciate this, however, we need to re-visit the Clausewitzian category of Absolute War.

[12] Clausewitz, *On War*, Ed. & Trans. M. Howard and P. Paret (Princeton, N.J.; Princeton University Press, 1984), 58, 63.

[13] Ibid., 70.

As is well known, Clausewitz discussed war in two guises – Absolute and Real War. Early in *On War*, he presented the 'essence of war [...] as an eruption of force and violence',[14] which he understood as 'true war, or *absolute war*'.[15] For Clausewitz, this 'true war, or absolute war' was nothing but 'a struggle for life and death – a struggle, that is, in which at least one of the parties is determined to gain a decision.'[16] The implicit annihilation that awaited the participants of Absolute War – abiding by its logic of strikes and counter-strikes – was a fact that was not underestimated by Clausewitz. Indeed, he frequently cited the example of the campaigns of Napoleon as being a proximal condition of Absolute War in Real terms. In other words, for Clausewitz, Absolute War – presuming no external influence – was the maximum effort, applied repeatedly, at a decisive point, for a decisive decision, *with a single logical object*: Absolute defeat of an enemy. This 'logic', was in Clausewitz's words, war's '… *natural tendency* […] *in its philosophical and strict logical sense alone and does not refer to the tendencies of the forces* […] *including* […] *the morale and emotions of the combatants*.'[17] Clausewitz further asserted that this logic remained true regardless of whether war was a duel between two contestants, or a hostile engagement between coalitions of nations. Based on the above, it could then be said that Absolute War displays two characteristics: (1) by virtue of being, at the least, co-constituted by 'blind natural force', it is, to some measure, independent of the political because as a pure expression of blind natural force, the 'succession of blows and counter-blows' need have no basis in the political. (2) When this blind natural force does manifest itself within the political, it can potentially 'usurp the place of policy the moment policy had brought it into being; it would then drive policy out of office and *rule by the laws of its own nature*.'[18]

---

[14] A. Gat, *A History of Military Thought – From the Enlightenment to the Cold War* (Oxford, UK: Oxford University Press, 2001), 225.

[15] Clausewitz, *On War*, 488-9.

[16] Ibid., 488.

Thus, we find Clausewitz insisting that 'in the field of abstract thought […] it [i.e., war] reaches the extreme, for here it is dealing with an extreme: *a clash of forces freely operating and obedient to no law but their own* […] *an almost invisible sequence of logical subtleties*.'[19] Clausewitz absolutely insists that this 'logic' of war that determines the 'succession of blows and counter-blows' is not simply an in-human logic, but also a non-human one. It is equally critical that we recognise Clausewitz's subtle but simultaneous assignment of two versions of Absolute War – as the 'logic of war' independent of the political *and* as 'the logic of war' at the disposal/service of the political. But Clausewitz's initial assessment of the dangers posed by Absolute War 'in the field of abstract thought' – that is, regardless of whether or not it is subject to the political – remained unchanged. He contended that the logic of war, in the Absolute sense – devoid of emotion, morale and feelings – was marked by *its desire* for the annihilation or absolute defeat of the enemy and thus was dangerous and destructive.[20] Indeed, he also added the corollary that in its 'true' state, this logic – even when manifested within the political – was equally (and more to the point, materially) destructive and, therefore, dangerous – as, Clausewitz claimed, it was in the hands of Napoleon.[21] Thus, it is not surprising to find Clausewitz insisting that any theory of war *must* make room for Absolute War. Indeed, according to Clausewitz, Absolute War *must* be the principle that is invoked to 'form a general point of reference, so that he who wants to learn from theory becomes accustomed to keeping that in view constantly, to measuring all his hopes and fears by it, and to approximating it *when he can* or *when he must*.'[22]

---

[17] Ibid., 89 (All emphasis mine) Note that Clausewitz, elsewhere in *On War*, insists that 'war has no logic, it only has a grammar'. This is, to say the least, a most curious statement for Clausewitz is claiming that a 'grammar' is bereft of logic.

[18] Ibid., 87 (My emphasis).

[19] Ibid., 78 (My emphasis).

Clausewitz' recognition of Absolute War as a non-human/inhuman condition also brought in its wake the discomforting knowledge that, in war, the strategic ensemble that thought or thinking forms breaks down into fragments, thereby shattering the logic of sense and sensibility that lends consistency to thinking as a strategic act. Hence the fact – in Field Marshall Moltke's words – that 'no plan survives contact'. This was obvious to Clausewitz as he sifted through history, both ancient and contemporary to him. In other words, Clausewitz realised that while the Realness of Absolute War could not be wished away, Real War was merely a partial manifestation of Absolute War within a geopolitical space, and always prone to morph into Absolute War, especially when in the hands of a 'genius'. Not only did this realisation prove sobering for Clausewitz's theoretical ambitions, it also posed a fundamental problem of ontological proportions: If, as Clausewitz discovered, war is essentially violent, chaotic, an instance where the logic of Reason potentially comes to a standstill, and which is only marginally subject to the space of the political as an instrument, then it remains essentially outside the field of circumscription laid down by Reason. It is at this point that Clausewitz displays his Kantian roots and opts to strategise war itself – a martial version of the Kantian manoeuvre to strategise Reason. To this end, Clausewitz presented Absolute War as a transcendental category grounded, not only on three critical a prioris – blind passion, hatred, and being amenable to control by Reason in the form of the State – but also on one categorical imperative: '*[a]ct only according to that maxim whereby you can at the same time will that it should become a universal law.*'[23] These allowed Clausewitz to develop an innovative theory of war which, while remaining true to the surface of the earth (for Clausewitzian war does play itself out on the surface of the earth), remained outside the specificity of any geospatial territory.

---

[20] Nb. Clausewitz, as this study suggests, implies a non-human conception of the 'logic of war'. In this sense, it is outside the framework of Reason. But, as we will see, this is also strictly not the case.

[21] Clausewitz, *On War*, 529-30.

[22] Ibid., 581 (Emphasis in original).

---

[23] I. Kant, *Grounding for the Metaphysics of Morals* [1785], 3rd ed., trans. J. W. Ellington, (London: Hackett, 1993), 30.

Thus, by positing an *ex-terra* space inhabited by universal laws, Clausewitz made the operative concept of war, while terrestrially linked, extra-terrestrial. In this way, he was able to strategise the phenomenon of war using universal laws that, while grounded in the concept of Absolute War, prioritised the historical and real-time *experience* of Real War – that is to say, war as experienced by privileged ontological objects like the human, the state, the citizen, and the subject. But Clausewitz remained aware of the potency of Absolute War and cautioned his readers that Absolute War was the 'absolute' and 'real' referent when thinking about war, and that Real War was a fragile construct easily disturbed by the intensity of Absolute War. Thus, for Clausewitz, the key strategic question was: How to keep the disturbances caused by the intensity of Absolute War at bay? Clausewitz's little-mentioned ontological question, of course, remained: How to think when thinking is chaotic at its core?

Following Clausewitz's lead, we have, particularly since the seventeenth century, studied war and its conduct as a command and control problem – both at the geo-politico-strategic level and at the operational and tactical levels. The ground on which these levels stand is the earth, or more precisely, the surface crust of the Earth – the base geophysical material on which Real War is actualised and experienced. Thus, while the uneven surface of the earth may throw up from time to time shadows that interrupt, subvert and dislocate the transcendental logic of Clausewitz's theory of war, the rationally-designed, technologically-enhanced and constantly transforming command and control assemblages that confront such chaoplexic conditions are – especially in the Information Age – well-equipped to penetrate these shadows and hidden spaces and bring 'war to Reason'. Thus, we find that in the context of the emerging theories and doctrines of Network-centric Warfare (NCW) (and their attendant technical modes of being martial) and of the GWOT, especially in the post 9/11 timeframe, we still tend to explain the experience of Real War (unexpected 'terror-attacks' as signatures of planetary-scale insurgencies) in command and control terms. In other words, the most recent 'revolution in military affairs' – which, arguably, is increasingly transforming how combat operations are conceptualised and executed – while introducing us to the haptically-diverse experience of war, nevertheless, has not abandoned its Clausewitzian roots, which lie not on or in the Earth but at some distance from it, but which effectively dominate the surface-area of the earth without accessing its depths. This is most evident when we consider how terror-operations (as the emerging signature of war) are conceptually enframed by mainstream military theorists and strategy thinkers in the twenty-first century.

TERROR-OPERATIONS THROUGH A CLAUSEWITZIAN LENS

In a recent essay, 'Surprise and Terrorism: A Conceptual Framework', Morris advises us that '[i]n the domain of war, adversaries have sought to capitalise on the enemy's surprise and fear since time immemorial.'[24] He further suggests that the element of 'surprise', which he distinguishes from the 'strategic and tactical surprise' that occupies so central a position in State-centric models of war, is the critical tactical enabler of terrorist operations which, when coupled with 'fear', occupies a 'central place in the tactical and strategic repertoire of the terrorist.'[25] Further, Morris asserts, 'terrorists use the gun and the bomb as delivery systems for the real coercive instruments in their arsenal: surprise and shock. Used in this way, surprise itself becomes a potent weapon.' Thus, he claims that:

---

[24] Morris, 'Surprise and Terror', 2.

> [i]t [surprise] has enabled relatively small groups of sub-state actors to compel entire governments to action and ultimately change the course of history. Whether terrorists have been strategically successful in this regard is debatable, especially if we define success narrowly as the full realisation of professed political aims. However, their ability to alter the landscape of our security environment and change the way people think and behave is undeniable.[26]

While one cannot fault the operative logic that drives these observations, it is, however, obvious that Morris's effort is geared to render the act of the 'terrorist' into terms that would be recognisable, and ultimately combatable, by State-centric forces. But this is a counterproductive gesture for, while in the first instance it restricts us to thinking about war and 'acts of terror' within the dominant Clausewitzian framework, ultimately it only serves to distract us from the potency and essential indifference of the forces embodied in the 'terrorist'. Before we proceed to direct our attention to these anomalous 'terroristic' forces and the means by which they establish their counter-flows, it is necessary carefully to extract the finer implications of Morris's suggestions. Not only will this help us to establish the limits of the martial imagination within which, we suggest, Morris and much of the strategy and policy-making community is being held captive; it will also help set the stage to discuss the key elements of what we contend is the emergent condition of the SIMAD's *polemos*.

---

[25] Ibid.

[26] Ibid.

What is immediately evident from Morris's analysis is that, though he professes to lay a great deal of importance on the element of surprise and valorises it – albeit for analytical purposes – to the point of asserting its central importance as a key weapon of choice in the terrorist's arsenal, he also remains curiously ambivalent about the sustainability of this 'weapon'. This should not be surprising because the regime of thought from within which Morris discusses 'surprise as a weapon' is constrained to consider 'surprise' as a singular instantiation of a 'terrible', or more prosaically, of a 'dramatic' Event, which is engineered to create a temporary condition of strategic, operational and tactical asymmetry between opposing forces thereby conferring the advantage of an operational initiative on the side that 'creates' the element of surprise. In other words, surprise, which is a function of 'time' or, more precisely, of 'timing', is taken to be an extremely fluid and vicarious element which, by definition, remains only transiently viable as an instrument of war.

While in passing we note that this, curiously, applies as much to the dynamics of the conventional battlefield as it does to terroristic operations,[27] the major problem in the consideration of 'surprise' as a 'weapon' is that if we (here following the thread of Morris's argument) are cognisant with the unreliability – in terms of its sustainability – of such an instrument, then surely those who launch and conduct terror-operations would also be aware of such a limitation of this 'key weapon'. And, if this is so, then would it not make sense to ask if our (and, according to Morris, the 'terrorist's') strategy of considering 'surprise' as a weapon – in however transient a form – is indeed valid? In other words, would the 'terrorist', who appreciates (according to Morris) the key tactically-enabling properties of surprise as a weapon – as much as we do – not be aware of the implicit limitations of this 'weapon'? Would not the 'terrorist' also recognise the 'use it *and* lose it' characteristic of 'surprise' as a tactical enabler? And if so, then why would the 'terrorist' consider 'surprise' as a *key* weapon in his or her arsenal in the first place? Thus, despite Morris's exegesis, this assertion – that surprise is a critically coercive weapon of terror – remains unconvincing. But this is not because Morris's insight about the criticality of surprise is flawed: indeed, as an insight into terror-operations in the twenty-first century it is of great value. Yet the framework within which he chooses (or is compelled) to discuss it detracts from its merits.

---

[27] Thus, for example, the Nazi invasion of the Soviet Union was a 'surprise' – tactically and strategically – though as Morris suggests the 'strategic surprise' was more a function of Stalin's unwillingness to consider intelligence inputs from various sources – most famously from Richard Sorge – seriously. More pertinent is the 'tactical surprise' that the Wehrmacht achieved at various points (but not at every point) along the invasion front. See, for example, Paul Carell, *Hitler Moves East* (New Delhi: Natraj Publishers, 2008).

While we should avoid falling into the conceptual restrictions within which Morris's exegesis is trapped, we should also not be too hasty to dismiss outright his insight into the role and importance of 'surprise' in the context of terror-operations, especially when referring to the emergent martial landscape. Indeed, if we leave aside the constricted conceptual space from within which Morris conducts his discussion, his identification of the element of 'surprise' should be applauded, for, among other things, it allows us to highlight an alternative version (and consequent implications) of 'surprise', whose vector runs along a completely different path than that which Morris places as a central feature of his 'conceptual framework'. As we will see, there are other ways to think about 'surprise' in the context of terror-operations that – while refusing to be subsumed under the notion of 'surprise' that Morris draws on and which is grounded, for the most part, within our traditional martial imagination – provide a sustainable substrate from which the four protocols of the SIMAD's *polemos* draw their materiality. As we shall see, it is only when considered in this way that 'surprise' truly becomes a lethal weapon, or more precisely, achieves a lethal state of latent weaponization which not only is sustainable, but also forms the kernel of a radically counter-tactical 'concept of operations' for the battlefields of the twenty-first century.

Further, it also appears that Morris remains ambivalent about how to define 'success' in the context of terror-operations. Predictably, Morris seeks to understand 'success' in state-centric terms, which leads him to offer, in this instance, a 'narrow' understanding of the word in terms of the realisation of professed political aims. Inexplicably, however, Morris fails to consider seriously the epigraph – that which opens both his essay and the present one – taken from Brig. Malik's rendition of the *Quranic Concept of War*, which states that '[*t*]*error is not a means of imposing decision upon the enemy; it is the decision we wish to impose upon him*'. It is precisely here not only that the weakness of Morris's 'conceptual framework' is exposed; but also that terror operations – especially in the twenty-first century – pose two insuperable challenges to the Clausewitzian paradigm of thought under which Morris labours and which he leaves unaccounted for.

First, the primacy given to the achievement of political aims and objectives, which drives the teleological engine of the Clausewitzian theoretical framework – the coordination and deployment of a variety of (often state-mandated violent) means towards the achievement of specific political ends – is markedly absent, at least in what Malik has to say about the Quranic Concept of War. Of course, it may be argued that 'terrorist' entities – Al Qaida being one of the recent and foremost examples – have a number of identifiable and specific geo-political objectives such as the ousting of foreign (primarily American) troops from the land of Mecca and Medina; the establishment of Sharia (possibly on a global scale); the establishment of a Caliphate-mode of Islamic governance; addressing of the Palestinian, Kashmiri and other such-like questions – which resonate, albeit tangentially, with state-centric geopolitical aims and objectives.[28] But the suggestion to take these overt 'political announcements' as central defining features that render and explain – particularly in terms of their operational signatures – entities and agencies such as Al Qaida and their more local and particularised affiliates, is not simply misleading, but also dangerous. It is misleading because it is grounded on the premise that the use of terror-operations is the means by which such ends may be achieved. In other words, among other things, the implicit suggestion is that once such goals and objectives are achieved, such entities and agencies would (or may be expected to) call a halt to their operations. Malik, of course, disabuses us of such fantasies by clearly identifying the 'objective' of terror-operations: '[*o*]*nce a condition of terror into the opponent's heart is obtained, hardly anything is left to be achieved*'. From this it should be evident that terror-operations, which may either masquerade or be misconstrued as essentially an extreme form of political action, are in reality, *or more precisely, in the reality of the terror-operatives*, outside the context of the political. Thus, while overtly political objectives may be identified and advertised in the context of terror-operations, the primal motive for such operations is not held hostage by and to any kind of political framework.[29] To us, operating from within a patently sub-political Clausewitzian framework, such a posture is bound to seem either incomprehensible or, at best, a lethal manifestation of an irrational, 'other-worldly', anarcho-nihilistic, hyper-violent militant *mode of operability* which breaks the link between 'cause' and 'effect', thereby defying any reason and logic that we may be familiar with. In the face of such a 'reality' our traditional acts of strategising deconstruct, often violently.

---

[28] Kilcullen discusses these and other political considerations in his four models of enframing the 21st Century Security environment – Globalisation Backlash, Globalised Insurgency, Islamic Civil War, Asymmetric Warfare. The alleged political goals of what is termed as Islamo-fascistic terrorism fall primarily within the first three models. See D. Kilcullen, *The Accidental Guerilla: Fighting Small Wars in the Midst of a Big One* (London: Hurst and Company, 2009), 7-28.

Additionally, 'strategic thinking' of the kind indulged in by Morris is also dangerous because to attempt to construe (post)modern terror-operations as being politically motivated (which, by extension, implies that they may be addressed by conventional military means and/or by dialogue or diplomacy) fosters the illusion that 'terror-operations' are necessarily organised around an exploitative principle which, given its shock-value, offers the greatest return at a minimal cost. If we continue to think along these lines we remain susceptible to believing that, when considered in military terms, neutralising the element of surprise would effectively stunt the proliferation of terror-operations, which is effectively what Morris implicitly suggests. Thus, our exegetical and analytical exercises – such as the one authored by Morris – in remaining within the confines of the Clausewitzian universe, tend to ignore the stark warning that Malik issues to us – for, in that one sentence, he disabuses us of our propensity to read terror-operations from within the Clausewitzian regime of thought. It is not surprising, therefore, as Negarestani points out, that Faraj would thunder at us: '*war is not a theatre, you infidels*'!

---

[29] We can see one potent example of this in Faraj's text.

Secondly, we should not hesitate to recognise that 'surprise' in the context of the terror-operations of the twenty-first century refuses to be separated either from 'terror' or from 'fear'. Morris implicitly avoids addressing this when he suggests that the 'shock' element of a 'surprise' is the prime generator of the conditions of 'terror' and 'fear', thereby drawing a distinction between 'surprise' as a 'means', and 'terror' and 'fear' as a transient stage, towards the attainment of identifiable political ends.[30] What Morris seems to be suggesting is that 'surprise' is one of the key, indeed indispensable, 'tactical enablers' that allows the condition of 'terror' and 'fear' to be imposed on the enemy for the purpose of some political gain. To support this, Morris quotes from Abu Sa'd al-Amili's work, 'Learning Lessons from the Raids on New York and Washington', wherein the latter suggests that '[t]he blow came as a *surprise* to everyone. This is the essence of the Prophet's wisdom and the soundest application of his advice:

---

[30] Morris, 'Surprise and Terror', 5-10.

"*War is deception*".'[31] Further, Morris quotes from Ayman al-Zawahiri's text 'Knights under the Prophet's Banner', wherein al-Zawahiri explains that '[t]he targets as well as the type and method of weapons used must be chosen to have an impact on the structure of the enemy …'[32] From examples like these, Morris draws the questionable conclusion that '… the *manner* in which the enemy is attacked is important in itself …'.[33] Yet it is curious that he does not recognise or acknowledge that by suggesting this, he blurs the very distinction that he draws between the 'strategic and tactical surprise' that is often effected on the conventional battlefield and the element of 'surprise' involved in the Al Qaida attacks on 9/11.

Morris's distinction between 'surprise on the battlefield' and 'surprise' as employed by 'terror-operators' pivots around the fact that on the conventional battlefield, 'surprise' is a means of throwing an enemy off balance, whereas in the context of terrorist activities, it is a weapon of choice, with which to conduct 'psychological warfare'. But this distinction is at best dubious for if, as Clausewitz noted, 'surprise' is '… not only the means to the attainment of numerical superiority; *but it is also to be regarded as a substantive principle in itself, on account of its moral effect* […] [and] when it is successful in a high degree, confusion and broken courage in the enemy's ranks are the consequences …',[34] then the difference between the 'surprise' that Clausewitz refers to and that engineered by Al Qaida on 9/11 is minimal or non-existent: Both point to the same object – creating a debilitating psychological impact on the enemy. Thus we could say that 'surprise' is as much of a 'tactical enabler' for Clausewitz as it is for terror-operators like Al Qaida. But if we say this, then we would be in danger of misunderstanding not only the grounds from which terror-operations, particularly in the twenty-first century, operate, but also the existential grounds or condition that they seek to establish.

II. THE SIMAD'S *POLEMOS*: A BRIEF OVERVIEW

Accounts that purport to depict the evolution of warfare – from the seventeenth century onwards – generally do so by identifying various 'generations' of warfare. Thus, the First Generation was characterised by static or positional warfare; the Second Generation, also known as 'firepower/attrition warfare', was characterised by an hierarchical command and control system wherein decision-making was centralised and bureaucratised; the Third Generation, known as 'manoeuvre warfare', was characterised by an increasing de-centralisation of command and control – the principle of *Auftsragtaktik* or 'mission command' is the key defining feature of this 'generation' of warfare, which was raised to an operational art-form in the Second World War by the armoured formations of the Wehrmacht; finally, the Fourth Generation of warfare is characterised by an increasing and intense focus on the chaos and complexity of the battlespace. In Fourth-Generation Warfare, the operative 'concept of operations' is organised around the exploitation of the 'fog of war'. The most visible emergent manifestation of this is highlighted in the theories of network-centric warfare (NCW) and in the associated doctrines of 'swarming on the battlefield'.[35] A more recent, and in many ways innovative, account describes the evolution of warfare – within the same timeframe – by organising itself around the metaphors of the clock, the steam-engine, the computer and the network, thereby speaking of the evolution of war as transiting through the mechanistic, thermodynamic, cybernetic and chaoplexic stages.[36] Yet both these accounts remain firmly within the circumscription of the political. In other words, regardless of how descriptive and innovative these accounts are with regard to the history of the evolution of warfare, they do not deviate from the core Clausewitzian principle which instrumentalises war as a tool of politics and a means by which political objectives, in extreme circumstances, may be achieved.

---

[35] W. S. Lind, *The Four Generations of Warfare*, at http://lewrockwell.com/lind/lind26.html. Accessed on July 23, 2009. Apparently, there is now some talk of a Fifth Generation of Warfare that works around the following concepts: close-coupled systems, self-organisation, emergent properties (particularly 'intelligence'), stigmergy, and the concept of complexity arising from simple processes. See J. Robb, *Brave New War: The Next Stage of Terrorism and the End of Globalization* (John Wiley: Hoboken, New Jersey, 2007). Of course, the same problem that afflicts the previous accounts of the evolution of war reappears here, albeit in different terms. Regardless of how the 'solution' is framed, Robb's account remains enmeshed with the classical Clausewitzian framework, which subordinates war to the political. It seems that Robb's account is focused on the problems associated with 'globalisation' and sources the 'threat' to global malcontents (mis)using the benefits of globalisation. Thus he recommends the withdrawal of the nation-state from 'national security' activities and letting private individuals and corporations take over that function. Robb apparently does not see the paradox implicit in his recommendations – for all that he is doing is to replace the nation-state system with a corporatism of sorts, which would function in place of the nation-state. It is a classic case of replacing one institution with another, albeit more flexible, institution.

[36] See A. Bousquet, *The Scientific Way of Warfare: Order and Chaos on the Battlefields of Modernity* (London: Hurst, 2009).

It is perhaps the allegiance to this foundational principle of modern International Relations, indeed of the concept of the political, which blinds Morris and other like-minded analysts to the existential threat that the nation-state system faces from the terror-operations that we are increasingly becoming familiar with today. In other words, while terror-operations, as Morris suggests, do and have changed the security environment in the twenty-first century, they have also done much more. They have terminally infected the fabric of the nation-state system and, in turn, are compelling nation-states themselves to morph in strange and unexpected ways. While such a change is underway, it should be appreciated that the means by which this change is taking place are not at all revolutionary. In fact, terror-operations in the twenty-first century do not have 'revolution' as an objective, which is also what sets them apart from the traditional and historical theorists and practitioners of anarcho-terrorism.[37] Additionally, this change is imperceptibly gradual and is not, as is commonly (mis) understood, an intervention from an 'outside'. Rather, it is a productive, indeed creative, albeit *intensive,* operation whereby the very fabric of the modern Western industrialised and informationalised state and society (and that of its clones outside the geo-territorial western world) is gradually becoming un-done. As such, therefore, this emergent battlespace is radically different from that which is showcased by the Clausewitzian sub-political category of Real War from which we have thus far derived the analytical and operational principles and tools by which we attempt to understand and contend with terror-operations.

---

[37] Some of the more prominent practitioners were François-Claudius Ravachol, Auguste Vaillant, Émile Henry, who, among others, were inspired by the revolutionary and counter-revolutionary theories and doctrines of the Kropotkin/ Malatesta/Nechayev/Bakunin-inspired school of anarchism.

PRECURSOR TO THE SIMAD: THE NOMADIC WAR-MACHINE

In the context of mainstream International Relations, 'threats' to the nation-state are generally alleged to originate from two distinct locales: (1) from outside the State, and (2) from within it. From the 'outside', 'threats' to the nation-state are either posed by other nation-states or by non-State actors, while in the latter case, the threats are local, that is to say, they are systemic in origin. Yet to say that threats to the nation-state originate from the 'outside' would be a misnomer, for the perception and consequent contextualisation of the threat takes place from within the confines of the nation-state, thereby establishing the originary limits of the threat. This is reflected in the Clausewitzian consideration of war as an instrument of politics, which is also how 'Absolute War' is brought to Reason. By contrast, the original Deleuze-Guattarian formulation of the nomadic war-machine, which they placed at a locale external to the State, allows us to (re)consider war from a non-Clausewitzian point of view. In other words, it allows us to engage with war from a site outside the circumscription of the nation-state and its transcendentally-generated geo-territorial map of materiality. In this exteriority, the Deleuze-Guattarian war-machine is 'irreducible to the State [...] outside its sovereignty [...] prior to its law: it comes from elsewhere.'[38] As such, therefore, the Deleuze-Guattarian war-machine is '... of another species, of another nature, of another origin'.[39]

The key to understanding the Deleuze-Guattarian formulation of the war-machine is to understand its

---

[38] G. Deleuze and F. Guattari, *Nomadology: The War Machine*, tr. Brian Massumi (New York: Semiotext(e), 1986), 2.

[39] Ibid., 3.

'nomadic' nature while at the same time keeping in mind that 'war' (political war), for the nomadic war-machine, is only of secondary importance. To draw our attention to the 'exteriority' of the nomadic war-machine, Deleuze-Guattari insist that we pay close attention to the 'nomad', who, they assert, has 'a territory'. In other words, we are meant to recognise that the nomad traverses 'paths' which are defined by points or nodes – watering holes, dwelling points, and points of dispersal. These points and nodes are mere transit points which are temporary locales of assembly and dispersion for the nomad. The nomad, unlike other sedentary or even migratory entities, is not attracted permanently to such points or nodes. As Deleuze-Guattari put it, 'the life of a nomad is intermezzo'.[40] In this way, Deleuze-Guattari distinguish the nomad not only from the sedentary, but also from the migrant: Unlike the nomad, the migrant, who is also a 'mover', travels along a path determined between two points. In the migrant's case, however, the points determine the path and the points are the *telos* of the movement that the migrant undertakes. This is *contra* the nomad, whose movement is in itself the *telos*, with the points or nodes being transient points of rest and refreshment. The paradox that the nomad presents, however, is that – according to Deleuze-Guattari – although the defining nature of the nomad may seem to be movement, as Toynbee points out, the nomad actually does not move. Rather, Deleuze-Guattari say, the nomad occupies 'space'.[41] Thus, in Deleuze-Guattari's words, 'the nomad is one who does not depart, does not want to depart, who clings to smooth space left by the receding forest, where the steppe or the desert advance …'.[42] In Toynbee's words, nomads fling '… themselves upon the Steppe, not to escape beyond its bounds but to make themselves at home on it.'[43]

---

[40] Ibid., 50.

[41] Ibid., 51.

Deleuze-Guattari's theorisation of the nomad and of the nomadic war-machine is, of course, more complex and extensive than the above may suggest. However, for our purposes, it is only necessary to recognise that the Deleuze-Guattarian model of 'nomadology' brings into sharp relief the functioning of nomadic war-machines and the nature of their relationship with the nation-state and its instruments of war. In summary, the diagram that they draw of this relationship may be sketched out in the following way: (1) War-machines (which are nomadic assemblages) are external to the State; (2) Since the nomad, essentially, occupies 'space', it is the State which intrudes into this 'space' of the nomad, which is where and how the State comes into conflict with the nomadic war-machine; (3) Thus, under specific circumstances, the State is able to 'capture' such war-machines and internalise them. In other words, the State is able to instrumentalise these nomadic war-machines and use them for its imperial purposes; (4) As such, therefore, the State is always predisposed to assume a pre-emptively offensive stance to seek the 'unknown unknowns', for the latter pose the greatest threat to the systemic health of the State; (5) However, in the process of doing so, the State also runs the risk of being enveloped by the war-machine, in which case the State ends up being a mere assemblage of the war-machine. In this form, the war-machine assumes global proportions and is able to create a condition of terrifying peace;

---

[42] Ibid.

[43] A. Toynbee, *A Study of History* (New York: Oxford University Press, 1947), Abridged by D.C. Somerville, 168.

(6) This peace is a function of the constabulary role that the global war-machine plays by integrating within itself what were originally the policing and juridical functions of the State into a panoptical device of control and discipline; (7) The principal concern of such a worldwide war-machine is to exercise systemic control of, among other things, the State. In other words, the worldwide war-machine looks to identify any sign or activity that may disturb the systemic balance of the State/war-machine. In Bousquet's terms, the worldwide war-machine seeks to contain, but also to sustain, a chaoplexic condition that carefully calibrates the degree of turbulence allowable within the system. In this way, the worldwide war-machine is able to maintain the productive health of the system by monitoring the productivity (and, one could also add, the vitality) of the constituents of the system. This Deleuze-Guattarian model of the nomadic war-machine which, when captured and re-deployed by the State, assumes the terrifying model of a worldwide war-machine that has run amok, is not merely a piece of speculative theory. In the context of the emerging theories and doctrines of network-centric warfare, their model of the instrumentalised war-machine has taken on a very real materiality. Thus, for example, we can find an uncanny resemblance between the doctrine of battleswarms and the Deleuze-Guattarian model of the worldwide war-machine, both of which – at least in theory – are envisioned not simply in global terms, but on a planetary scale.

In the context of twenty-first-century terror-operations, therefore, if the terror-operator is assumed to be a 'nomadic war-machine', then the State's counter-terror (and counter-insurgency) doctrines are signatures of the domestication of the nomadic war-machine.[44] Of course, there is a viable case to be made that post-modern terror-operators like Al Qaida are not nomadic war-machines. Yet, their operational signatures lead us to suggest that, at the least, they simulate the operational modes of nomadic war-machines. However, this does not negate the State's ability to capture this extra-State war, which it makes its own. Given this, the following question arises: Is there 'a war' that remains outside the ability of the State to make its own – thereby precluding its ability to bring war to a 'reason' comprehensible by the State?

SIMADology

Given that most discussions on terror-operations – within the current geo-politico-philosophical regime of thought with all its attendant anthropocentric socio-political and psychological biases – sink steadily into the morass of an anthropocentric notion of 'terrorism', our intention, as we clarified at the outset of this essay, was to explore the possibility of an alternative regime of thought within which we contend that the SIMAD's *polemos* is gradually unfolding. But to do this, merely asserting the emergence of this polemical condition is not enough. We cannot begin to speak of the SIMAD's *polemos* without explicating the vicious circle that binds the diachronic relationship between the Terror-Operator, and its anterior/prospective actions, which are only retrospectively recognisable as the Event-Terror. Thus, in the context of the SIMAD's *polemos*, we begin by positing nothing less than an absolute annihilation of any residual interstices that may have kept apart the Terror-Operator and the Event-Terror – thereby collapsing them into and onto each other. This, in turn, requires us to direct our attention to an alternate martial space – let us refer to this as a 'chthonic battlespace'.[45]

---

[44] One example of the State's capture of the war-machine and its redeployment in the service of the State and its subsequent running amok is the U.S. support for the Afghan Mujaheddin to fight the Soviet Occupation of Afghanistan. After the defeat and withdrawal of the Soviets, these same Mujaheddin engineered a machinic assemblage which turned upon their erstwhile benefactors and locked them into a battle that rages on to this day. See M. Kakar, *Afghanistan: The Soviet Invasion and the Afghan Response, 1979-1982* (London: Univ. of California Press, 1997). See also Steve Coll, *Ghost Wars: The Secret History of the CIA, Afghanistan, and Bin Laden, from the Soviet Invasion to September 10, 2001* (London: Penguin Press, 2004).

Engaging with the chthonic battlespace – which is marked by a tension characterised by flows and counter-flows of forces of intensification and torsional disintensification (envoiding)[46] – is but the first step in articulating an alternate regime of thought wherein the Clausewitzian paradigm of War loses its subjective anchor and objective reality. When considered in the context of the chthonic battlespace, the Clausewitzian 'concept' of Absolute War breaks free from its ideational limits (imposed on it by the experience of Real War) and freely colludes with any and all counter-resistant media to creatively produce a differential calculus of itself, which infects and re-infects not only the resisting medium, but all machinic assemblages that (per)form with/in that medium, while at the same time – with clinical and excessive precision – virally proliferating itself, thereby creatively generating 'milieus of terror' far in excess of any geopolitical sources and levels of terror that we may be familiar with. In this way, the SIMAD's *polemos* assumes a chasmic[47] pertinence, which is both endemic to the regime of thought that generates it, and which is, more terrifyingly, in excess of it.

---

[45] The word 'chthonic' is derived from the Greek χθόνιος – *chthonios*, 'in, under, or beneath the earth', and from χθών – *chthōn* 'earth'; pertaining to the Earth; earthy; subterranean. Further, the Greek word *khthon* is one of several words for 'earth' which, typically, refers to the 'interior of the soil', rather than 'the living surface' of the land (as *Gaia* or *Ge* does); or the 'land as territory' (as *khora* [χώϱα] does). Our use of the word 'chthonic' invokes the reference to the 'interior of the soil' that the word *khthon* involves.

[46] Thanks to Reza Negarestani who formulated this excellent phrase (email exchange, July 18, 2009).

In the context of this essay, therefore, the SIMAD's *polemos* is an un-grounding that destabilises any and all territorial limits, including those 'territories' inhabited by the Deleuze-Guattarian 'nomad'. By positing this, we are also suggesting that the SIMAD's *polemos* is 'the ripping of the ultimate horizon of materiality which poses a posterior disjunction to thought and enacts the anterior submission of originary ontological difference to the non-belonging principle of the void.'[48] It is in this sense that the SIMAD's *polemos* is the signature of an ultimate dissolution of materiality. Chasmic Terror, in the context of the SIMAD's *polemos,* then, is in the first instance the disjunction of thought – for in such a theatre of dissolution, thought loses its traction. Thought, in these conditions, is wrecked by a torsional movement that not only contorts it beyond recognition, but also, more importantly, first disinters and then dissolves it, thereby bringing into sharp relief the possibility of a chasmic immaterialisation with its attendant annulment of all ontological privileges.

---

[47] In this context, the urge to use the word 'cosmos' or 'cosmic', was very compelling. However, etymologically, it would have been impossible to support. In Ancient Greek, the word 'kosmos' refers to an 'orderly arrangement' (cf. Homeric 'kosmeo', used of 'the act of marshaling troops'), with an important secondary sense of 'ornament, decoration, dress'. Pythagoras is said to have been the first to apply this word to 'the universe', perhaps originally meaning 'the starry firmament', but later it was extended to the whole physical world, including the earth (see http://www.etymonline.com/index.php?search=cosmos&searchmode=none). In this essay, the use of the word 'chasmic' is made keeping in mind the following: (1) It is a derivative of 'chaos', which is itself derived from the Gk. khaos 'abyss, that which gapes wide open, is vast and empty,' from *khnwos, from PIE base *gheu-, *gh(e)i- 'to gape' (cf. Gk khaino 'I yawn,' O.E. ginian, O.N. ginnunga-gap; (2) Hesiod ('Theogony'), describes 'khaos' as the primeval emptiness of the Universe, begetter of Erebus and Nyx ('Night'), which is much closer to what we intend to convey in this essay, as opposed to, say, how Ovid (*Metamorphoses*) – who opposes Khaos to Kosmos, 'the ordered Universe' – uses the word. Further, the Greek word 'tarakhe' stands for disorder, which may be posited as the opposite of the word 'kosmos'. We have chosen to use the word 'chasmic' derived from Hesiod's use of the word 'khaos', rather than from Ovid because (1) the latter's use of the word pits it directly against 'kosmos' and thus may be considered to be closer to 'tarakhe' or 'disorder', and (2) when derived from Hesiod, the word conveys a more open-ended sense. Of course, we also contend, contra Hesiod that chaos is not a signature of 'pure emptiness of the Universe, rather that it is a 'force-plane' that is anterior to even matter, which is also our provisional explanation of Hesiod's assertion regarding the 'primeval emptiness of the Universe' as the begetter of Erebus and Nyx. (see http://www.etymonline.com/index.php?search=chaos).

Given this, the SIMAD is therefore the point or locus where this ripping of the ultimate horizon of materiality is tangibly 'visible'; for it is at that site and in that instant that the curvature of a radically open-ended exteriority – the chasmic – exhibits itself while simultaneously generating an anomalous field or milieu wherein the vastness of the chasmic non-belonging exteriority is expressed by means of a distinct tellurian-originated difference. This expression of tellurian difference is nothing but the signature of an ill-fated, that is to say tragic, complicity of interiorised tellurian energetico-structures – that produces, by means of difference-engines, a spatio-temporal materiality – with chasmic non-belonging exteriority. It is critical to note that this complicity, though tellurian in origin, is absymally virulent – indeed this is what makes the SIMAD and its ensuing *polemos* so hard to pin down, yet so very real. The SIMAD is a passage, a traversing, an emergence, an eruption, which involves – indeed, compels – a tragic but essentially indifferent complicity between tellurian structures and chasmic dissolutions, resulting in the disintegration of all ontological privileges. It is for this reason that even when we speak of 'acts of terrorism', which are instances of tellurian 'terror-events', we cannot do so without reference to breakage, dismemberment, dissolution, incomprehension, stunning affectivity, and ultimately, to death. But, lurking behind our tellurian-specific explanations, what we are actually referring to is this breakdown and dissolution of patently tellurian ontological privileges, caused by seemingly abrupt interventions and of their scattering into the darkest recesses of a chasmic void of non-belonging-ness.

---

[48] Reza Negarestani (email exchange, Jun 23, 2009).

The question that begs our attention at this point concerns the implicit difference that emerges as a consequence of our reference to the *tellurian* and *chthonic*. Etymologically, the tellurian refers to surfaces that presume a *terra firma*. It is a material surface, albeit without any depth and, interestingly, it is the implicit plane on which, it is theorised, advanced war machines, such as those proposed by Deleuze-Guattari, express their so-called rhizomatic martial tendencies. But it is important to note that the mobile assembling and dis-assembling that the Deleuze-Guattarian war machines revel in, while seemingly liquid in their movements, are nevertheless restricted to the 'matter' of the tellurian surface; for the '*firma*', in the tellurian context, guarantees the ontological structural integrity of 'matter', which blocks off access to 'depth', that is to say, to the Abyss of non-belonging-ness, and which, while being 'smooth', also retains the potential of 'striation'. The chthonic, on the other hand, is the substrate of the tellurian. It is a liquidly intensive and interiorised chasmic force-plane, which is smooth, free-flowing and open-ended. The chthonic plane is thus an interiorised chasmic horizon – an 'inscape' of chasmic non-belonging-ness. In this sense, it is anterior to matter itself (and thus to all ontological attributes that lend structural integrity) and therefore precludes the possibility of any kind of striation. On this plane, which is seething with unrestrained forces, transitorial assemblages such as Deleuze-Guattarian war machines are irrelevant. They gain no traction. They are unable to maintain their integrity of assembly, however fleetingly. Thus, the Deleuze-Guattarian *concept* of rhizomes, presuming that it is a prelude to the formation of difference-engines, is effectively only possible on these chthonic planes, for the latter allow for a free play not simply on surfaces, but also in terms of a chasmic depth. Given this, therefore, it can be said that tellurian surfaces and structures have as their conditions of possibility the chthonic, but chthonic planes remain without any such preconditions. Indeed, the chthonic chasmic forces, while instrumental in creating the conditions of possibility of matter (and the consequent ontological privileges), are also always-already dissolving such conditions on the tellurian non-planar surface. In other words, the chthonic chasmic forces are always subversive forces which, while engendering differential engines that populate the tellurian surfaces, also continually spike them.

Now, these terrifying chasmic interventions, which in the tellurian context are akin to 'eruptions', cannot be plotted against and within a tellurian matrix, because they are the unfolding of always-already interiorisations of a chasmic exteriority that lurks as a substrate to the tellurian surface and that takes place along and across the continuum of tellurian space-time. Thus, to say that the SIMAD 'intervenes' is not to suggest that it is an invasion from an 'outside'; rather, it is to suggest that the rupture of the tellurian space-time continuum is akin to a cross-sectional cut which, while slicing through the non-planar tellurian surface of exteriority, nevertheless envelopes the tellurian exterior, thereby interiorising it within the chasmic exteriority. There is something very excessive and disturbing about this, for the buckling and contortion that takes place in this envelopment results in a compression and an ultimate collapse of the tellurian space-time continuum into a site and locale of immeasurable density; while equally, and more importantly, it is also a shattering and a scattering of all energetico-structures beyond all tellurian confines. This is the site of the SIMAD's battlespace – the martial *intermezzo* in which strategy decomposes into pure tacticities and where combat has less to do with destruction, and more to do with the alchemy of decay. Thus, it becomes impossible to capture – let alone domesticate – the SIMAD. It is only possible to be complicit with/in it – but on the non-negotiable condition that we also share its non-linear and cross-register movements, which spiral away chaotically beyond any tellurian boundaries into a chasm of non-belongingness. The paradox is that while we are swept up and along by this terrible intervention, equally, we cannot help but contribute to it: in the process, we – as tellurian-specific energetico-structures – become un-done!

When considered from the perspective of the tellurian non-planar surface, the 'intervention' that we have just described is indeed paradoxical: For it is inconceivable that we are both the site wherein the affectivity of the SIMAD is exhibited and a co-constitutive element of the SIMAD itself. However, the paradox becomes, literally, immaterial if we posit that what is played out on this chthonic surface is the liquidity of the SIMAD's *polemos* on and in which we are no longer discrete and resistant energetico-structures negotiating the flows of the molten surface of the chthonic plane, fighting the insinuations of havoc that the SIMAD brings with it. Rather, we are discontinuous ensembles drawing our localised tactical consistencies from the very medium that constitutes the chthonic planar surface. In this way, while we are consumed by the SIMAD's *polemos*, we co-constitute it as well. It also follows, then, that when considered in the context of such chthonic planar surfaces, there are no discrete interstices wherein the politics normatively attributed to terrorism can be played out. Of course, this does not mean that the politics of terror are absent. They are certainly present, but only on the tellurian non-planar site to which we, operating on and within the liquid chthonic plane, are indifferent. But if this is so, then how can we account for the difference between the non-planar tellurian surface and the chthonic planar substrate? Is there not a sharp and distinctive originary difference between them?

To presume a difference between the tellurian and the chthonic is to reinscribe the presence and uninterrupted operation of a difference-engine which produces difference *qua* matter in the first instance. We have already suggested that such difference-engines only exist on the tellurian surface, which provides them with enough traction to be able to produce and proliferate difference *qua* matter. But equally, chasmic interventions subvert the output of these tellurian difference-engines (difference *qua* difference and, by implication, difference *qua* matter). Thus, while in the tellurian context, matter is indestructible, or irreducible, in the chthonic context, its (that is to say, matter/difference's) production is always-already a signature of its dissolution. As a pertinent aside, it is this force, on whose vector the dissolution of matter/difference is contingent, that Ferenczi indicates when he speaks of 'the complete dissolution of connexions and a terrible vertigo' in the context of the Ego.[49]

This vertigo, which is one of the signatures of an asymmetric dismantling of difference-engines, is a terrifying indicator of the SIMAD's passage involving chthonically interiorised chasmic forces through and beyond tellurian surfaces (and the implicit exposure of the interiorised chasmic horizon of a non-belonging exteriority, or that which we have referred to as the 'inscape' in the chthonic context) carrying along with them shattered tellurian energetico-structures (difference-engines), which rapidly decompose into ever receding fragments and grains within the chasmic void of non-belonging-ness. As a consequence, these interventions, by spiking the tellurian-specific difference-engines, bring about an ungrounding of the non-planar tellurian surface while remaining faithful to the creation of a 'new earth'. This is the passage of the SIMAD.

Considered in this way, then, it is tempting to understand the SIMAD as a very distinct and specific kind of a difference-engine – one that, while traversing along and across the tellurian surface, only plays the role of dis-integrating it. In light of our discussion thus far, it would appear that the SIMAD is a difference-engine engineered and empowered by chthonically-interiorised chasmic forces that arrive from unidentifiable locales of non-belonging and transit through to other such locales of non-belonging.

---

[49] S. Ferenczi, *Final contributions to the problems and methods of psychoanalysis* [1930] (London: Karnac Books, 1994), 222-3.

This would also account for our inability positively and effectively to enframe the SIMAD within a matrix of comprehensibility and would confirm the essential indistinguishability that we have previously attributed to it. If we give in to this temptation, however, we would be grossly misunderstanding the SIMAD.

The SIMAD is not a difference-engine, though it can masquerade as one when in hypercamouflage mode. Instead, the SIMAD is an *intensive mechano-in-organic insinuation (pre-shock and after-shock) of the passage of chasmic forces that riddles any battlespace constructed on the tellurian surface with 'hotspots' – sites or locales of eruption and escape (Levinas would undoubtedly refer to these as sites and instances of 'excendence')*.[50] It is *intensive* because, while on the tellurian surface, it appears as a pure and transparent spatio-temporal dynamism originating from within the enveloped void hidden within the surface of the earth. It is *mechano-in-organic* because, identified in the tellurian context as a fleeting agenticity originating from a locale of non-belonging-ness, it is primordially machinic but also takes on a progressively solid and organic form as its evolutionary cycle cuts through the tellurian surface. It is an *insinuation* because, on the tellurian surface, it leaves nothing more than an aftershock as traces of its terrifying passage. As such, therefore, the SIMAD brings into sharp relief the post-vital, that is to say the post-Evental, status of tellurian battlespaces.

Now, the theory of NCW which, when considered in its abstract – albeit perversely grotesque – form closely approximates the Deleuze-Guattarian conception of a 'worldwide war machine that has run amok', posits that the key to its efficient operability is its ability to 'sense and respond'. This it proposes to do by progressively collapsing the links between the 'sensor' and the 'shooter'. The ideal condition, implicit in the theory of battleswarms, is the meshing of the 'sensor' and the 'shooter', which allows for the prosecution of what is termed Just-in-Time (JIT) Warfare. Indeed, it is precisely this lack of distance between the general's map-table (screen) and the battle that, in the first instance, allows Just-in-Time War to be imagined. In other words, the viability of the JIT concept of operations rests on the ability to operate in Real Time. But, as we have seen, when played out on a tellurian surface, the map-table is a 'map' that plots the Event-Terror *after* its instantiation – that is to say, retrospectively. In other words, what is reflected on the general's map-table is a trace (or alternatively, an after-shock) of the Event-Terror – it is, in this sense, behind Real Time.

---

[50] Acknowledgment to Reza Negarestani for the phrase 'mechanorganic insinuations of sheer havoc', which I have slightly modified to read 'mechano-in-organic' (email exchange, Jun 23, 2009).

The strategic ensemble that the theory of NCW assembles is the most recent – that is to say, a postmodern – difference-engine that has emerged on the tellurian surface. Little wonder, therefore, that some of the leading theorists of NCW who lay a great deal of emphasis on the theory and emerging doctrine of 'battleswarms' would choose to understand the doctrine in terms of a 'seemingly amorphous, but […] deliberately structured, coordinated, strategic way to strike from all directions, by means of a sustainable pulsing of force.'[51] There are two implicit assumptions underwriting this emergent 'concept of operations': Firstly, that battleswarms – comprised of myriads of small, dispersed, networked and highly lethal mobile units – would disintegrate in battle; but also that they should be able to speedily reform to co-constitute a fresh battleswarm to deal with a 'new' threat. And, secondly, that under ideal conditions, the 'seemingly amorphous, but deliberately structured' form is held together by a 'sustainable pulsing of force'. The latter assumption is an interesting one, for it in turn presumes that these post-modern theorists of war have not only recognised the high intensity and multivaried forces that their technophilic battleswarms would have to contend with – that which we have previously identified as chthonically interiorised chasmic forces – but also that, eventually, there would arise the possibility to halt and effectively combat these 'unknown' forces.[52] The reference to the 'sustainable pulsing of force' is even more interesting, as it points to the implicit difference-engine that is operative within this net-centric 'concept of operations', which is designed (or perhaps destined) to function as the organising principle of battleswarms. This latter aspiration, we should not fail to recognise, is in keeping with the Clausewitzian tradition. Whereas Clausewitz attempted to contend with chaos and uncertainty in the context of war, and particularly on the battlefield, by instrumentalising (or alternatively, strategising) the genius, chance and uncertainty, and by theorising the very concept of war in a very specific way, his post-modern disciples, it would seem, are opting for a more technologically-grounded method to achieve the same end. In the latter case, the only way this can be achieved is if they somehow succeed in effectively sealing off the tellurian surface from the terrifying chasmic forces, which would entail a scenario that eerily echoes the

---

[52] The most recent attempt to articulate this has been Bousquet's *The Scientific Way of War*, wherein he used the term 'chaoplexic' to highlight the emerging model that such efforts of containment would deploy.

Deleuze-Guattarian vision of a 'worldwide war machine, which […] reforms smooth space [and] […] claims to control, to surround the entire earth.'[53]

What remains unaccounted for by and in this post-modern battlespace, which is possible to construct only on tellurian surfaces and which maintains its ideal objective in terms of spanning the entire tellurian surface, is the subversiveness of the chasmic forces – represented by the SIMAD – that confront it. This subversion – the dissolution of the materiality of the tellurian surface and of all associated energetico-structures – then, is the counter-tactical 'concept of operations', which is fleetingly instantiated by and as the SIMAD. Recognising this, albeit perhaps not in these specific terms, the tellurian-specific project of net-centric militarization attempts to 'humanise' the SIMAD (as a 'terrorist' or a 'terror-operator') thereby creating a distance (difference) between 'it' and the Event-Terror such that, to paraphrase Libicki, 'a fine enough mesh can be cast to catch "it", or indeed, anything'. The failure to do so, as is evident from our more recent experience of war in the twenty-first century, is becoming increasingly terrifying and, as such, it heralds the polemological condition that the SIMAD brings in its wake.

III. THE FOUR PROTOCOLS OF SIMADOLOGY

Based on the above, we are now in a position to articulate a rudimentary set of protocols by which the SIMAD operates:

---

[53] Gilles Deleuze and Felix Guattari, *A Thousand Plateaus: Capitalism and Schizophrenia*, Trans. Brian Massumi, (London: Continuum, 2003), 421.

First Protocol: The object of the SIMAD's polemos lies not in the perpetuation of war, but in the instantiation of a creative chemistry of decay.

Under the Clausewitzian model, war – which has been the exclusive preserve of the nation-state – has two critical centres of gravity: a geo-spatial locale and a psycho-social locale. Thus, Clausewitz was able to say that if either of these two centres of gravity of an enemy is dislocated, it is possible to impose our 'will' onto the enemy. Counter-intuitively and paradoxically, SIMADs work to sustain *and* decay both the geo-spatial and psycho-social centres of gravity of their targets of interest. Indeed, the continued presence and maintenance of such centres of gravity is critical for the SIMAD for, paradoxically, they are the very sources of nourishment of the 'agenticities' of the SIMAD. The first principle of SIMADology, therefore, suggests that the most conducive environment for the efficient conduct of operations is a state or condition of an 'uneasy' peace, which can be calibrated by the SIMAD between greater or lesser degrees of fear, surprise and terror which involves a weaponization of the chemistry of decay and dissolution. In this way, SIMADs seek to retain the ability to calibrate the condition of peace, thereby keeping the target's systemic health in a state of perpetual decay and consequent perturbation.

Second Protocol: SIMADology *eschews the 'theory' of strategy and wholly focuses on pure tacticity.*

SIMADs refuse to engage in operations that are strategically constructed and developed. Rather, they seek micro-local and vermicular opportunities wherein they exhibit their purely tactical stance. This suggests that there is a very high degree of contingency in the SIMAD's *polemos* and that the ecology within which SIMADs operate is a critical co-constituting element that determines the nature of operations that are engaged in. Thus, all attempts to strategise the SIMAD's *polemos* are always externally imposed onto the 'agenticity' of the SIMAD. In other words, while the agenticies of the SIMAD do not strategise, the resistant environment that they operate in seeks to strategise their actions – generally, by attempting to 'profile' such activities. It is interesting to note that this foundational principle in itself plays a key role in dislocating our attempts to deal with the polemological condition that the SIMAD creates. In other words, while we, from the outside, may strategise the SIMAD's actions, SIMADs themselves are astrategic. Thus, whatever strategic pattern-creating tools we use, the 'maps' they generate are always 'fictions' for they are only artificial overlays that we create over patterns that we draw, which are always post-Evental. As a consequence, they lend us no further insight into how and in what manner the SIMAD's *polemos* unfolds. The occasional successes we may enjoy serve only to further delude us into believing the 'full-ness' of what is, in reality, our own vacuous construct.

Third Protocol: All damage, however small and seemingly insignificant, is considered primary damage.

In the context of the SIMAD's *polemos*, all damage is primary and no damage is collateral. This implies that the operating environment of the SIMAD is an omni-dimensional field of targets and that all shapes, forms, structures, ideas and matter that constitute that environment, regardless of their normatively assigned value, are targets of equal value for the SIMAD. Thus, there is no distinction made between a 'higher value' target and a 'lower value' target. When considered in the context of geo-spatial targets and psycho-social targets, therefore, everything is 'fair game'. Targets are identified not in terms of 'value' but in terms of their ability to generate 'fear', 'terror' and 'surprise' that can sustain and prolong the chemistry of decay that the SIMAD fosters. Moreover, the operations that rely on such a targeting principle are not graded in greater or lesser degrees; nor do they necessarily have to be violent, though they always exhibit a latency of violence.

Fourth Protocol: SIMADs don't inflict (damage)*, they infect.*

SIMADs infect systems and structures rather than inflicting damage on them. As noted above, chasmic chthonic forces – embodied as the SIMAD – work to dis-inter the materiality of the tellurian surfaces by continually spiking the difference-engines that populate the tellurian surface. This spiking of difference-engines by the SIMAD, however, is rarely, if ever, revolutionary. Rather, it is evolutionary. This is primarily because SIMADs insist on reducing the 'matter' of tellurian-based structures by deploying a 'decaying' mechanism – a kind of *necrosis* that brings to mind the Aristotelian description of the torture methods employed by the Etruscan pirates, which involved tying up an offender to a rotting and blackening corpse. What followed such a practice was an almost philosophical chemistry of decay by which a living body was turned inside/out at a vermicular, albeit infinitesimal, level.[54] The reported outcome of such a procedure involved the living body becoming progressively blackened, or negrified, and rotten, to the point where both 'bodies' were eventually reduced to a dark mass of slime. This, as Negarestani puts it, 'signaled an ontological exposition of the decaying process which had already started within.'[55] In a startlingly similar fashion, the SIMAD is a signature of the ontological decay of the tellurian surface for the SIMAD performs an almost vermicular function as it rends the tellurian landscape. The slow and imperceptible reworking of the ontological chemistry of the tellurian surface by the SIMAD thus spreads like a rash or a lesion which slowly tears away at, or more precisely, de-materialises, the fabric of the tellurian surface thus exposing the liquid-like substrate of the chasmic chthonic forces on which the tellurian surface rests. In this way, the SIMAD – by invoking the principle of decay – undermines the tellurian surface and all structures and difference-engines that exist and operate on it. If, as we contend, this is the nature of the emerging *polemos* of the SIMAD, then the problems associated with developing a counter-terror strategy and doctrine for the State (which, we should not forget, is a patently tellurian structure) increase exponentially for the problem associated with the fourth protocol of the SIMADology is nothing less than the following – how to contain (and reverse) a process of ontological decay?

IV. THE SIMAD'S COUNTER-TACTICS OF HYPERCAMOUFLAGE[56]

Morris is right on the mark when he points out that despite his implicit doubts about the sustainability of the 'weapon of surprise', the security landscape has changed, thereby leading him to assert that there has been a concomitant change in the way how people think and behave.[57] Yet, based on how Morris sets up the space of confrontation – sub-state actors versus 'entire governments' – in this 'changed' security landscape, his 'conceptual framework' does not convey the radical changes that have taken place in the global security environment.[58] Thus, it remains for us to ask: how and in what way has the security landscape so radically changed and, more importantly, what are the counter-tactical principles that the SIMAD brings to the foreground?

---

[56] The term 'hypercamouflage', to the best of my knowledge, was first coined by Reza Negarestani in his essay, 'Militarization of Peace' in **COLLAPSE I**. It should be noted, however, that the Soviets did have an operational principle that they termed 'maskirovka' (literally: camouflage, concealment), which was most effectively used at the Battle of Kursk against the Wehrmacht in July-August, 1943. It is also alleged that the principle of 'maskirovka' was used, under Russian guidance, to conceal Saddam Hussein's air-defence system in and around the Baghdad area. Of course, there have been other famous instances of the use of the principle of 'deception' and 'concealment' in warfare. The Allied deception of the full extent and deployment plans during the Normandy landings in 1944 is a case in point.

[57] Morris, 'Surprise and Terror', 2.

[58] If we follow Kilcullen's analysis of the accidental guerrilla, we find that one of the key issues at stake, which make the prosecution of the GWOT a problem is that nation-states find themselves in confrontation with groups and actors who reside within nation-states that are allies and friends. In some cases, this hosting of such groups is fully supported by the State in which they reside. The prime example in this instance is the case of Pakistan, which is both an ally to the United States, but has also – via its intelligence agencies (the ISI) – supported, funded and facilitated various groups that have carried out terror-operations directly and indirectly against American interests within and outside the American 'homeland'. See Kilcullen, *The Accidental Guerilla*.

Reza Negarestani's reading of Faraj's polemical terroristic text, *Jihad: The Absent Obligation,* provides us with a valuable insight into a radically post-modern counter-tactical principle of martial operability – 'hypercamouflage' – which, we contend, is the key defining feature of the martial operability that the SIMAD exhibits.[59] Negarestani suggests that Faraj's notion of *Taqfiri*-ism – set in the context of a version of militant and subversive Islamism, which counts among its proponents Sa'id Qutb, the Egyptian theorist of Islamic Revivalism – is supplemented by the doctrine of *Taqiyya*, which is contorted out of 'its [...] defensive and devout function in the dawn of Islam [...] [which originally was] a justified concealment of true beliefs in situations where harm or death will definitely be encountered if true beliefs are declared (the wider meaning of *Taqiyya* being "to avoid or shun any kind of danger").'[60] Faraj's militant and subversive bent, in Negarestani's reading, takes this notion of *Taqiyya*, weaponizes it, and recommends its deployment as a supplementary mode of operability to the already militant terroristic *Takfiri* system. The consequence of this exercise is the emergence of the 'shadow terrorist', whose principle weapon of choice then would be a latent state of weaponization, but which would remain indiscernible to the keenest of eyes. Thus, as Negarestani puts it:

> ... the cover of camouflage can never be penetrated or disrupted, and...[t]he Takfiri's favoured mode of warfare is to program a new type of tactical line which totally blends with the enemy's lines in such a configuration that it introduces radical instability and eventually violent fissions into the system from within.'[61]

[61] Ibid., 55.

It will be evident at once that this vision of a battlespace, or in our context, of war, is radically different from the one that draws its inspiration from Clausewitz. There are a number of inferences that we can draw from this description of the battlespace of war. Firstly, the act of disappearing into the enemy is not a strategic act, rather it is pure tactical. It is eminently evasive and it is geared to meld (*melt* + *weld*) with the systemic elements of the enemy. This melding, ideally, is so refined that it becomes difficult, indeed impossible, to extricate the entities that have so fully merged within the system of the enemy. Secondly, as a consequence of this, the tactical principle of 'surprise', which plays such a critical role in Morris's 'conceptual framework', transforms itself into a systemic principle, which draws its sustenance from the very system within which the entities merge. Third, 'surprise' then is not an intervention from the 'outside'. Rather, it is, as Negarestani puts it, more akin to 'violent fissions into the system from within'. What ensues, therefore, is a radical destabilisation of the system, whose structural disabling is calibrated not by those elements legitimated to control the system, but by these mysterious entities that have disappeared within the system. The outcome of this, of course, is that the tactical initiative shifts from the system and its controllers (those who regulate and monitor the system's stability) towards the invisible malcontents that have infected the system. This calibration does not necessarily have to take the shape and form of 'visible' and 'public' Event-Terrors such as 9/11, the bombings in Khobar, Bali, London and Madrid, or the most recent indiscriminate shootings in Mumbai; it can even take place by mere insinuations. Thus, the deliberate leaking of (false) information pertaining to possible terror-strikes, the deliberate and calculated betrayal of the foot-soldiers – the raw recruits – to the keepers of the system, are all methods by which the calibration of the system takes place. Moreover, as a consequence of this, when the system attempts to correct itself, more often than not, by overcalibrating itself – the shooting of the Brazilian national in London is a stark example of this – it only serves to create further fertile conditions for the anomalous infectious agents to virally proliferate their infection of the system.

The policing of such an infected system, therefore, becomes a problem of gigantic proportions, for the key question that the policing agencies have to ask themselves is not simply: Who is the agent that is infecting the system?, but also: What does this agent look like? And, since the question is posed in this way, the technophilic response of the system is to reduce its constituents – individuals – to a computable and calculable entity, as is gradually being achieved by means of biometric identification cards, chips and passports. The objective of the system, therefore, is to create periodic pan-sensorial 'snapshots' of itself, by means of increasingly intricately-linked biometric databases, such that the health of the system may be monitored, and 'infections' that can or may destabilise the system contained, isolated and/or destroyed. Further, although the point is not central to our concern in this essay, it is worth pointing out that the key flaw in such an approach to security is that its operative assumption is that the infectious entities within the system have as their objective the collapse of the system. This is a tragic misreading of this security problematic given that for the infectious agents, the objective is to keep the system at a very precise tipping point which hovers between self-destruction and absolute consolidation –

a 'chaoplexic' condition – which is paralysing and terrifying. It is precisely in this way that 'surprise' and 'terror' come not only to be weaponized within the system, rather than at a locale outside it, but also to form the substrate on which the biopolitical model of the post-modern state manages itself. In other words, 'surprise', 'fear' and 'terror' become hypercamouflaged by being indiscernable elements of the system.

As discussed above, the passage of the SIMAD from among and between us is a process by which the dismantling of ontological privileges takes place. This dismantling and disintegrating of ontological privileges may seem paradoxical since the SIMAD, as an insinuation of havoc and disaster, tears down such privileges and throws 'matter' into the darkest recesses of the chasmic void, but at the same time engenders difference-engines on the tellurian surface. But we should be careful to recognise that this paradox is only apparent, because we, as tellurian-specific energetico-structures, are only able to discern (or, more commonly, insist on discerning) the passage of the SIMAD from within a tellurian-specific perspective, while not recognising and realising our essential complicity with and as the SIMAD. And, it is precisely in this way that the SIMAD executes its counter-tactical principle of 'hypercamouflage'. For it – that is to say, the SIMAD – rests within the tellurian difference-engines and energetico-structures. *In other words, SIMADs, in the first instance, reside in us.* Thus, to appropriate the Deleuze-Guattarian phraseology, the more arborescent the tellurian structures, the greater is the degree or revolutionary impact of the violence that the passage of the SIMAD entails, while by the same token, the more flattened or rhizomatic and assemblage-like the tellurian structures, the more evolutionary and less violent is their fate.

In the context of our discussion of the SIMAD and the chthonic battlefield, then, these mysterious 'agencities' are signatures of the passage of chasmic forces that relentlessly tear apart the tellurian structures with which we are more familiar and which, tragically, determine the mode and manner of how our state-centric counter-terror operational plans are conceived and deployed. In light of our discussion thus far, it will be evident that our attempts to deal with this emergent situation are worse than inadequate. Even the principles and doctrines of NCW which – despite Peter Singer's contention that they miss the point of 'future war'[62] – constitute perhaps the most advanced theory of war and combat that has seen the light of day since Clausewitz, suddenly finds itself unable to come to grips with the SIMAD and the *polemos* that it brings in its wake. Ultimately, however, this failure is one of imagination rather than of our capabilities. In other words, not only does our current imagination of war fall short; we repeatedly fail to comprehend the existential threats that our more familiar tellurian structures – the nation-state being the most visible example – are increasingly beginning to contend with.

CONCLUSION

As can be expected, insinuations such as these reside outside the pale of the martial imaginations that are deployed on tellurian battlespaces, which is also why we have yet to find an effective counter-tactic to the SIMAD. Instead, and at the cost of repeating ourselves, what we have proceeded to do is to step up the production and proliferation of difference-engines, thereby developing a model of global security governance by which means we strive to harden the tellurian battlespace to a degree that we assume can withstand such chasmic interventions.

[62] P. Singer, *Wired For War* (London: Penguin Books, 2009).

In a recent study of the 'accidental guerilla', David Kilcullen marks precisely such an effort. While the ethnographic descriptions in Kilcullen's study are interesting enough, nevertheless, when he begins by seeking to understand the GWOT as 'a form of globalised insurgency, with a vanguard of hypermodern, internationally oriented terrorists […] making use of all the tools of globalisation [while at the same time seeking] […] to organise, aggregate, and exploit the local, particular, long-standing grievances of diverse [...] social groups',[63] we already know (1) the nature of the terrain on which he is seeking to operate and (2) the strategic remedies that he will eventually offer at the end of his study. It is clear what Kilcullen is attempting. Firstly, he is intent on establishing a global tellurian battlespace, which is the space in which the GWOT is fought. Therein he proposes to establish smaller discrete battlespaces which, when considered in net-centric terms, are high-resolution magnifications of sections of the much larger and wider global battlespace. Following this, Kilcullen, taking cover behind the subjectivity implicit in traditional ethnographic studies, proposes to construct another battlespace with an even finer resolution, such as Libicki's original formulation of 'the Mesh and the Net', imagined as being fine enough to catch anything may be realised. In the process, however, Kilcullen is unable to provide us with a single clue as to how to halt the slow but steady seepage of terror, fear and surprise that oozes from the chthonic battlespace and wreaks havoc onto and into the tellurian one – for, despite the identification of such 'accidental' guerrillas, the bombings continue, the tellurian battlespace keeps getting ripped apart and the energetico-structures that are the 'matter' of Kilcullen's study keep getting infected with the non-belongingness of the void.

---

[63] Kilcullen, *Accidental Guerilla*, xiv.

Studies and policy recommendations such as Morris's and Kilcullen's thus fail to recognise that the tellurian logic that drives a statement such as the following: '[t]he dynamic interaction between the modern international system of nation-states [...] and [the] two discrete but often interconnected and loosely cooperating classes of nonstate opponent – terrorist and guerrilla, postmodern and premodern, nihilist and traditionalist, deliberate and accidental – may be part of what gives today's "hybrid wars" much of their savagery and complexity',[64] is an essentially flawed one. Flawed not simply because of the manner in which the groups that such studies and analyses identify and differentiate as postmodern and premodern are falsifiable, but because they fail to recognise that embedded within these very groups is a kernel of the chasmic void and that the resistance that they offer on the tellurian battlespace (which is all that Kilkullen can recognise) is itself a signature of the passage of the SIMAD.

Thus, Morris's, Kilcullen's and other suchlike analytical studies, whilst otherwise engaging accounts of 'post-modern terrorism' and of 'the accidental guerrilla', betray a fealty to a patently Clausewitzian imagination of war and consequently, when considered in the context of the chthonic battlespace, remain insufficient in their imagination to contend with the SIMAD and the virulent *polemos* that it beings in its wake. It is, therefore, little wonder that Kilcullen (whose analysis and 'recommendations' may be proposed as being representative of the state-centric response to the terror-operations in the twenty-first century) would close his account of the 'accidental guerrilla' by enumerating a number of interesting conclusions and recommendations, which he contends would aid us in combating terror-operations, or what he refers to as 'hybrid wars' in the twenty-first century:

---

[64] Ibid., xv.

> 1. This will be a protracted conflict.
> 2. We need to take a measured approach to national mobilisation.
> 3. We need to disaggregate and distinguish between enemies.
> 4. We need to use military force extremely sparingly.
> 5. The role of government agencies needs to be limited.
> 6. Non-military means need to receive greater emphasis in national security.
> 7. We need to emphasise the primacy of virtue, moral authority, and credibility.
> 8. We need to rebalance capabilities.
> 9. We need to rein in unsustainable spending and consolidate.[65]

Some of these recommendations leap out at us for what they imply in the context of our discussion: Firstly, there is the overall and implicit edge of palpable paranoia in these recommendations. Does this betray a fear of the envoiding that we have suggested lies within the energetico-structures that populate the battlespace that Kilcullen is familiar with? Secondly, there is the recognition that this 'battle' will be protracted – amazingly, Kilcullen suggests a 50-100 year timeframe! Whether the structural foundations of the nation-state, which are being constantly eroded and/or morphed by the chasmic forces that we have referred to, in addition to information and communication technologies, will be able to retain their integrity over such a period remains surprisingly unquestioned. Indeed, it remains an a priori assumption that the nation-state will be able to retain its current form and structure, albeit with a few minor adjustments. This is reflected in a number of Kilcullen's recommendations, such as the need to consolidate; the need to conserve resources; the need to rebalance capabilities, etc. Further, Kilcullen sets out the basal features of the nation-state – moral certitude, virtue and credibility. By positing this, as is perhaps evident, Kilcullen attempts a reinscription of the subjectivity of the nation-state, thereby making a valiant effort at reinforcing the tellurian non-planar surface on which energetico-structures such as nation-states thrive. Most interestingly, Kilcullen also makes a direct reference to the production of difference-engines whereby a disaggregation and distinguishing of 'enemies' can take place. In the context of our discussion, and when considered in light of the post-9/11 global security scenario, this should not be surprising for, if our thesis that difference-engines are continually spiked by the SIMAD's insinuation of a chasmic envoiding holds true, then this recommendation of 'disaggregation and distinguishing' – at least in the sense in which Kilcullen means it – is stillborn. Thus, only when we begin to recognise and appreciate the ensuing implications of this radically different notion of the *polemos* that the SIMAD brings in its wake, will we be able to account for the gradual and imperceptible morphing of what today passes as the post-modern face of the global insurgency that seems to have gripped the world of nation-states.

---

[65] Ibid., 284-7.

And finally, to appreciate the passage of the SIMAD, we need to break the transcendental logic of the Clausewitzian architectonic of war within which theorists and practitioners of war like Morris and Kilcullen offer their analyses. As we have seen, the tellurian battlespace is one which is artificially constructed by the Clausewitzian theory of war in a bid to keep the terrifyingly Real prospects of Absolute War at bay. As a consequence, in order to avoid chthonic magneto-dynamic attractors – the SIMADic insinuations of disruption, wreckage and distortion – the transcendental logic of the Clausewitzian architectonic of war expresses a false fealty to the earth, for it hovers like an 'ultimate horizon' that attempts to enwrap and smother the earth within its tenuously constructed net-centric war-machines whose generative principle is engineered by the production and sustenance of difference-engines. These Clausewitzian war-machines do not originate from the earth; instead they arrive from a transcendental plane virally proliferating on and across the tellurian battlespace. Bringing with them a strategy of stratification, these tellurian war-machines have as their first order of business the object of establishing a plane of logistics across the tellurian non-planar surface. The ambition is stark: To Determine the Future of a New Earth. However, the mysterious liquidly molten chthonic plane, while not overtly spiking this surface ambition of tellurian-specific war-machines, churns the tellurian surface by means of an infinitesimal vermicular process, breaking apart the plane of logistics on which the Clausewitzian theory of war is grounded. Thus, the SIMAD, riding the anomalous vectors of chthonic magneto-dynamic flows, ungrounds the tellurian surface. Consequently, the Clausewitzian plane of logistics contorts into a cesspool of constantly wrecking difference-engines, resulting in the fragmentation of associated energetico-structures, which are hurled into the deepest recesses of a terrifying chasmic void. To presume that these fragments are pushed into a space exterior to the earth would be a tragic misunderstanding of the advent of Absolute War. On the contrary, the void is chasmically in-depth with the earth – that is to say, it is in complicity with the chasmic Abyss that Nietzsche steeled himself to stare back at when it glared balefully at him. This glaring back and forth is not a 'confrontation' or a combative stance between us and the SIMAD. On the contrary, it is the signature of a sub-surface movement – a complicity of visions between the chasmic void of non-belonging-ness and ourselves, where we are nothing but chasmic envoidings in deep cover or in a mode of hypercamouflage as tellurian-specific difference-engines and energetico-structures. In other words, in the Age of Simadology, we are the SIMADs. We are that which decays *and* the agents of decay. We are expressions of the terrifying envoiding chemistry of decay.

Undercover Softness: An Introduction to the Architecture and Politics of Decay[1]

Reza Negarestani

Amongst philosophers and theologians of the Middle Ages, few did not make at least a tangential remark on a particular or general aspect of decay and putrefaction. Whether in the context of theological quandaries concerning the world of beings or in the context of philosophy and the science of the age, mediaeval thinkers touched on putrefaction as a problem too intimate with the world of beings or the *explicatio* of the universe to be brushed aside on emotional or rational grounds. Yet even among this rot-frenzy of the Middle Ages, there are only a handful of passages that directly focus on the implications of omnipresent problems which decay and putrefaction give birth to. One such passage can be found among the pile of proto-scientific works on impetus theory ascribed to the German theologian and mathematician Henry of Langenstein, also known as Henry of Hesse the Elder.

---

[1] This essay was extensively developed from a seminar originally given at The Centre for Cultural Studies, Goldsmiths, University of London, in May 2007. Whilst the arguments and analyses are different, the fundaments are still the same. I could not have written this essay without engaging commentaries provided by Robin Mackay, Ray Brassier, Eugene Thacker, Nick Land, Mark Fisher, Eyal Weizman, Susan Schuppli, and Luciana Parisi, who chaired the seminar.

Henry poses a ludicrously bizarre yet metaphysically troubling question regarding the possibility of the generation of one species from the putrefying corpse of another species: that of whether a fox can spontaneously be generated from a dog's carcass. Even more grotesquely unsettling is Henry's strong suspicion that 'it is not clear whether all men are of the same species or not, and so too with dogs and horses; [since] corpses which had been of the same species when living might differ in species from one another when corrupted.'[2] For Henry of Langenstein, putrefaction creates a differential productive field in which natural evolution is transmogrified into a sinisterly putrid inter-species production line. The so-called beloved creatures of God, in this corrupt scenario, are so unfortunate that they might be the festering fruits of rotten dead worlds and corpses. It is not only that forms of different species can overlap in decay, but that, according to Henry of Hesse, following the scholastic polymath Nicole Oresme and his theory of qualities or accidental forms, in putrefaction one species can uniformly or difformly deform in such a way that it gradually assumes the latitude of forms associated with other species. These deformities can progress to such an extent that one species might engender an entirely new species, an unheard-of thing, a universe whose reality can only be speculated upon. The gradational movements of decay – its vermicular liquidation across all latitudes and longitudes – thus create fields of differential deformity wherein the rotting corpse of one species or formal category interpolates between all other known species. In other words, gradients of decay or the blurring movements of rot

---

[2] L. Thorndike, *A History of Magic and Experimental Science*, Vol III (New York: Columbia University Press, 1934), 485.

calculate latitudes and longitudes peculiar to other species by interpolating other forms between them. These interpolated forms are in fact derivatives of the initial form of the decaying species, putrid or thawing forms which are derived as the process of decay differentiates or gradually subtracts from a formation or structural framework. This is suggestive of an affect without the positivity of affirmation – a becoming devoid of desire but driven forward solely by the creeping power of thawing forms and their differentiation across the latitudes of forms already taken by other bodies and entities. In this sense, *we can say that in putrefaction the universe is calculated; yet even more importantly, the universe that is sensed or speculated, whether as an idea or a materialized form, is the calculus of an infinite rot* – this is the belated epigraph from which we shall begin our investigation into the architecture, mathesis and politics of decay:

> The world has its origin in putrefaction.[3]

THE CORPSE OF WORLD POLITICS

> The whole world is full of corpses.[4]

If political systems are constituted of formations – both in the realm of ideas and in concrete structures – then, like living species, they also are subject to the troubling deformities brought about by the process of decay. In fact, Henry of Langenstein's formula of decay as a weird interpolating or extrapolating differential dynamism calculating the entire universe through the putrefying gradations of a corpse finds its most refined expression in politics and on socio-political grounds. The power of differential interpolation or weird affective dynamism lends the idea of localized or isolated decay a universal twist. What is rotting is indistinguishable from the wholesome remainder: not only can the decaying part generate the healthy parts through differentiating into their forms and ideas, the healthy parts themselves may indeed be the gradients of a decaying part. That is to say, in decay the origin qua the ideal shrinks more and more toward nothing and becomes unrecognisable, whilst the idea is spewed forth from the differential subtraction of the ideal. To put it differently, in putrefaction, it is not the decaying formation that is derived from an idea, but the idea that is differentially or gradationally formed through putrefaction. The idea, accordingly, is a deteriorating husk belatedly formed over an infinitely shrunken ideal. It is in this sense that the most proper form of a political formation – its idea – can be the product of a process of decay feeding simultaneously on the unidentifiable corpse of the ideals of that system along with the putridly amalgamated forms of other decaying systems.

---

[3] This remark is associated with the Friulian miller Domenico Scandella, also known as Menocchio, who was declared a heresiarch by the Inquisition and burnt at the stake. See C. Ginzburg, *The Cheese and the Worms: The Cosmos of a Sixteenth-Century Miller* (London: Routledge & Kegan Paul Ltd, 1980), xi.

[4] From *Sweet Movie* (1974) written and directed by Dusan Makavejev.

The process of decay constructs the idea only as a byproduct of the differential regurgitation of a shriveling body which is in the process of becoming less and less, without ever finding the relief of complete annihilation. This is to say, once again, that the troubling aspect of decay has to do more with its dynamism or gradation than with its inherently defiling nature: The most proper form of a formation such as a political system is not enveloped, as an origin or a priori ideal core; it is rather unfolded as a form which is differentiated a posteriori from the putrefaction of that formation or political system. The ideas of the wholesomeness and decaying (whether in regard to design, function, economy or ideas) of socio-political formations, accordingly, are posited as the latter products of a putrefying system. Yet this is not where the scenario of rot ends. Decay does not result in an equivocation between putrid and wholesome; it rather constructs *both* ideas as its gradationally proper forms, so that what is considered wholesome can in fact be seen as a rotten derivative of an initial construction that has limitropically diminished. The reverse of this scenario is not only possible but is even more prevalent: through putrefaction, the system or construction can assume forms and ideas associated with those systems or constructions which have – whether rightly or wrongly – been assumed wholesome.

The obvious, yet gullible, objection is that such an investigation of the politics of decay is not a universally or globally-relevant political issue or project, because a discussion of political rot is supposedly relevant only once one makes assumptions about the Middle East or the Balkans. In other words, in order to speak of political decay and its mechanisms, one has to provide an example such as Dubai or Bucharest – otherwise the problem of decay is not that relevant. If this is not a blind and oversimplified identification of world politics, it at least indicates a failure to understand the mechanisms at work in decay. Not only because a rotting political formation can germinate other forms which might overlap revolutionary, emancipatory and civilised political formations, but also because Western political formations and civilisations might indeed be the degenerate forms of an already rotten and limitropically decomposed Middle-Eastern or Balkanese socio-political formation. In this sense of putrefaction and rot as persisting and creeping, political decay casts a morbid shadow on the question of relevancy (or irrelevancy) and swiftly neutralises the idea of a 'localized rot'. There is no decay whose swollen and slimy nodules of rot – its differentiated forms – have not already interpolated themselves between all known and unknown forms in the softest and smoothest way possible so as to disguise the deterioration or putrefaction of the whole. These are just a few of the numerous conclusions to be drawn from a politics of decay; conclusions that hardly any political system or agency – despite testifying to the current fetid atmosphere of world politics – is ready to admit. The reason for this ironically passive stance, frequently espoused by both the right and the left, is that such conclusions overthrow certain presumptions about the fundaments, ideas and concrete formations of socio-political systems and agencies. What putrefaction changes, mimics and hollows out is not only the surface of a system but also its essential interiority, all the way down to its inner ideals, fundaments, axioms and so-called necessities. It is this spontaneous threat against the interiority of the system or formation from within that no political system or agency is willing to acknowledge, for it is exactly the admission of such a resident threat – the chemical evil of decay – that casts doubts on one's political agenda or the legitimacy of an emancipatory socio-political formation. In short, to profoundly doubt the interiority of one's politics or political agency can hardly be anything other than a real political *faux pas*.

World politics and its systems – whether erected on the side of outright repression or on the side of emancipation – have every reason to be wary of a politics of decay, because the ultimate truth of decay is that it is a building process that builds a nested maze of interiorities whereby all interiorized horizons or formations are exteriorized in unimaginably twisted ways. To put it simply, decay is a process that exteriorizes all interiorities via their own formal or ideal resources (capital?); and in doing so, its politics and schemes of complicity operate not on behalf of the interiority of the horizon (of any kind) but rather on behalf of the exteriority which demands their inflection to the outside. For this reason, we shall simultaneously explicate the weirdly-resident, or undercover, exteriorization of decay in regard to space and time so as to subsequently draw out a formalism of decay's dynamic process wherein the abstract matheme of decay gains a chemical disposition, and the chemistry of putrefaction is distributed in a mathematical space. The embracing of a politics of decay as a building process toward exteriority, and the possibility of political intervention against decaying formations, both demand a systematic investigation that criss-crosses territories associated with chemistry, mathematics, biology, geophilosophy and ontology. Without such a preparatory investigation, one risks either over-aestheticising decay as the fetish of the age, or falling into a moral credulousness that sooner or later will host a political parasite which cannot tolerate any doubt regarding the wholesomeness of its interiority. As a mere overture to the politics of decay, this essay, accordingly, proceeds to expound on the calculus of putrefaction – together with the reason as to why we associate decay with calculus – with respect to its conceptions of space, time, form and dynamism.

Since decay is the intensive destiny of terrestrial life and ecology, tellurian formations and earthly thought, a geophilosophy or tellurian politics that does not inflect upon its intensive destiny has its head – speaking entirely non-metaphorically – in the clouds.

DECAY AS A BUILDING PROCESS, OR EXTERIORIZATION VIA NESTED INTERIORITIES

The first axiom of this essay is that decay is a building process; it has a chemical slant and a differential (hence open to mathematical formalisation) dynamic distribution. The process of decay builds new states of extensity, affect, magnitude and even integrity from and out of a system or formation without nullifying or reforming it. The decaying formation is dispossessed of its chances to die or to live wholesomely, to be abolished, reformed or delivered to its origin. For this reason, decay is an irresolute process of building that potentiates architectures which, whilst infinitely open to new syntheses and transformations, cannot undergo complete annulment or return to their original form. One of the basic questions regarding decay as a building process is, thus far, the question of its vectorial alignment: Is decay a positive or a negative building process? The answer is that the building process of decay is subtractive, which is to say, it is concurrently intensively negative and extensively positive. Just as the vector of perpetual subtraction adds to the subtracted amount by deducting from what is subtracted, the process of decay generates differential forms by limitropically subtracting from the rotten object. This process is manifested vividly in a rotting fruit as it generates gradients of decay and differentiates into close and distant derivatives, whilst at the same time progressively shrivelling. The differential or germinal derivatives of the rotting fruit – its rancid smell, maggots, colour changes, secreted enzymes, etc. – constitute the positive building vector of decay which extends outwardly. Yet the shriveling body of the fruit as it continuously shrinks forms the negative building vector of decay. As long as the fruit shrivels, it gives rise to its derivatives or gradations of decay. In fact, the longer and more the object shrivels, the more remote and distant – hence weirder – its putrid derivatives and differential forms become. The process of decay, therefore, exacerbates the blackening indeterminacy already entrenched at the heart of subtractive cosmogenesis: It is no longer possible to determine how much one can lose or shrink before it becomes void and zero or how much one can spew forth and generate before it becomes nature or God.

Confronting the problem of the *infinitesimal persistence* of the decaying object, it becomes increasingly difficult to say when the process of decay ceases to exist and is supplanted by complete ontological annulment or extinction. However, the problem of infinitesimal persistence (becoming infinitely close to zero but never effectively becoming zero) poses yet another perplexing quandary in regard to the process of decay, a problem which can be summarized as follows: If the decaying object never completely disappears, and, in so far as it continues to become less, generates derivatives and maintains a germinal capacity, then does this mean that death never occurs and the minimally surviving object can never be fully exteriorized? An affirmative answer to this question surely risks advocating a form of vitalism that is ultimately unable to think exteriority. An outright negative answer can also lead to a form of utopian naivety for which the outside – viz. inflection upon death and binding exteriority – is always available and at hand. In order to examine the process of decay whilst avoiding such tortuous traps, we propose that decay as a building process renegotiates – or simply *twists* – the loci for the effectuation of architecture, exteriorization and binding death. In brief, the process of decay finds and develops a different site for the unilateral power of negativity. The infinitesimal persistence of the decaying object – in other words, its limitropic convergence upon zero – and correspondingly, its unceasing germinal power in decay, should not be examined in an isolated manner. In decay, the infinitesimal persistence of the decaying object marks a limitropic line of transition along which the interiority of one decaying object falls back onto the interiority of its constitutive ideas, and those ideas in turn are undone to other fundamental interiorities whose intrinsic nature is exterior to the decaying object. As the ideas break into their more fundamental but minimal ideas, the infinitesimal persistence of the object becomes asymptotic to the extinction of the object. Correspondingly, if in the subtractive logic of decay, *remaining* (viz. residing within the interiority of what is left) means *remaining less* (viz. moving in the direction of more fundamental interiorities which constituted the horizon of what had previously remained), then to remain indefinitely means to limitropically converge upon zero. Therefore, although the inward and depthwise movement toward the constitutive ideas or the ideal substratum which manifests itself as 'remaining less' happens only within the confines of different horizons of interiority, its dynamism limitropically embraces the *zero of ideas*. In doing so, the interiorized movement becomes asymptotic to a line of exteriorization upon which death is inflected, and objectal persistence in decay becomes an asymptotic expression of loosening into the abyss.

In order to simplify the above argument, we shall develop a spatial model for decay whereby both the infinitesimal persistence of the decaying object (i.e. a horizon of interiority) and its outward differential productivity become the essential vectors of a process of exteriorization – a *corrupt* method of binding exteriority. The reason why, in decay, binding exteriority occurs in such a twisted way, comes down to the following: living things undergo decay, not so much because decay and life come hand-in-hand, as because the living – whether living on a biological level or not – secures a horizon of interiority whose envelopment must be exteriorized according to the differential rates or gradients that bind the horizon to that which is exterior to it. In other words, if decay is most frequently associated with life, it is because the manifestations of life are all founded on horizons of interiority. All that is interiorized decays.

If the process of building is not exclusive to architecture and if, wherever building as a process is actualised, architecture too is potentiated, then the locus of architecture can also be renegotiated. Architecture and its socio-political aspects can be approached in territories where they are least expected. We call this architecture with an anomalous locus, *ex situ* architecture. The process of decay as a building process, as we will elaborate in what follows, generates an *ex situ* architecture where what is built cannot not be dwelled or grounded in any possible way. Because what is in the process of being built, in this case, is a nested exteriority wherein one interiorized horizon (such as the organism) falls back upon its precursor exteriority, which itself is another interiorized horizon built upon an exterior horizon which is in the process of loosening into its abyssal backdrop. Just as the lines of envelopment and growth for any horizon of interiority (whether the organism, earth, sun, or matter on the cosmic level) are convoluted and circuitous paths (*umwege*) toward the precursor exteriority, the line of exteriorization is also a circuitous path drawn along and through the horizons of interiority which fall back, decompose and loosen into each other.

Consider an elucidating – albeit reductive – example: Terrestrial organisms mark the organic interiority enveloped against the inorganic materials which under hospitable conditions can envelope the potencies of life. As both the vessel and the medium of complicity for inorganic materials, Earth is yet another interiorized horizon which is set against its immediate source of energy, the Sun. However, the solar empire is, in the same vein, an interiority enveloped and determined against its exterior cosmic backdrop. This nested continuum of interiorities goes on to the material substratum of all horizons. Yet even matter as the fundamental requirement for embodiment and materialisation is an enveloped horizon whose interiority and supposed necessity is a roundabout expression of a refractory indifferent universe in which even matter is an interiorized – hence idealised – contingency. Accordingly, what decay or putrefaction draws is a line of exteriorization toward the precursor exteriority. The organism decomposes into its inorganic terrestrial environment, the tellurian bedrock is in turn decaying into the solar horizon as the Sun's thermonuclear decay dissipates the star into its cosmic backdrop, whose material veneer, in turn, is peeling away. Decay draws a line of exteriorization which traverses the nested interiorities in order to asymptotically bind exteriority. Therefore its dynamism is subjected to differential bonds which connect and nest these interiorities within each other. For this reason, such a differential line of exteriorization or dissolution into conceptless exteriority is neither manifestly a *return* to an ideal origin nor a *decontraction* back into the originary exteriority where even matter enjoys no privilege of any kind. This is because decay's line of exteriorization builds a space of complicity between horizons of interiority wherein the unilateral power of exteriorization is mathematically and chemically contorted. This contortion or twist happens in a specific fashion: That which is exteriorized or dissolved into its precursor exteriority becomes a differential interpolation of a nested series of interiorities whose limitropic convergence upon zero (i.e. inflection upon death) has a weirdly chemical – thus contingent and productive – disposition which simultaneously forecloses the idea of return to the ideal origin and differentially convolutes the path of decontraction to the originary flatline of death. Let us recapitulate the reasons why the process of decay does not abide by the laws of return to the ideal origin and the energetico-dynamic principles of decontraction:

- The site where decay's process of exteriorization is effectuated is the interiority of the horizon. Therefore, the course of exteriorization conforms to the differential fields enveloped inside or extended from the interiorized horizon. Decay loosens up the interiority of the horizon, firstly through exploiting the horizon's own differential links between its actualities and potencies; secondly by conforming to the differential bonds between the interiority of the horizon and its precursor exteriority. Yet precursor exteriority (whether as the material, systematic, formal or ideal fundament, as in the case of inorganic materials and the organic horizon) is itself an interiorized horizon determined by its inner and outer differential bonds. This nestedness of interiorities wherein every idea or form differentially – and in this case regressively – inflects the next idea or form keeps decay's line of exteriority in conformity with the differential bonds and the increasing inflections of the nested horizons of interiority. Therefore, decay's process of exteriorization does not bind the outside from without so much as it binds the exteriority from within nested horizons of interiority. This binding of exteriority, however, is in conformity with differential fields inherent to each horizon of interiority as well as inter-connective differential bonds between these nested horizons. Consequently, the course of decay's process of exteriorization is conducted in accordance with spatial involutions, differential rates and modes of distribution immanent to nested interiorities. Since courses of exteriorization are subjected to differential peculiarities and twists of the nested space of interiorities, effects of exteriorization – that is to say, the effects of binding exteriority and inflecting upon death on interiorized horizons and formations – are also expressed in different ways. For this reason, the persistent involvement of nested interiorities undoubtedly complicates the philosophical, political and social implications of binding exteriority, inflecting upon death and extinction, for all formations and systems (from basic terrestrial formations to social networks, political systems and the horizon of thought). In decay, what is considered as the bedrock of the originary turns into a slimy swamp of nested interiorities where the bottom is always too soft and unsolid to hold or ground anything. The sinking is neither swift nor clean.

• The differential and regressive movement through nested horizons of interiority which the process of decay undertakes is not unidirectional and simplex, since, as argued above, this process conforms to the space of interiorities, which are nested within each other, not according to a one-to-one line of correspondence but according to a differential and multiplex nested structure. For example, in decay an idea qua an index of interiority is not merely differentially founded on one precursory idea but on a multitude of other fundamental and constitutive ideas which themselves are also inflected within different ideas. The image that the nested space of interiorities – as the site of decay – calls to mind is not a unidirectional tunnel of connected niches whose size and qualities are uniformly changing, but rather a rabbit warren or a worm-ridden cheese where every niche or hole opens into numerous smaller or larger interconnected caverns and holes. As the liquid that enters the first niche seeps into all such connected caverns, the gradationally rotting object, idea or formation also oozes, or more accurately, is exteriorized into the multitude of interiorities inside which it is nested. The model of exteriorization, in this sense, follows (1) the instantaneous rate of change between the decaying interiorized horizon and those non-uniformly nested interiorities into which it is being exteriorized, and (2) the instantaneous rate of change between the inter-connected multitude of interiorities which are differentially exterior to the decaying horizon of interiority. The idea X is inflected back upon its nested fundamental ideas which are themselves differentially interconnected (X inflects back to X_1, Y, Z, D, F, X_2Z_3, $X_3Z_2Y_1$, D_2, Y_2D_3, …). The process of decay, accordingly, traverses multiple ever-changing ideas or variables (as indexes of interiority). Therefore, in order to differentially exteriorize or putrefy an object, the process of decay must operate according to the instantaneous rate of change not only between the decaying object (the variable X) and nested interiorities gradationally exterior to it, but also between those interiorities / variables into which X is limitropically diminishing. The instantaneous rate of change, accordingly, is calculated between X and X_1, Y, Z, D, F, X_2Z_3, ... as well as between X_1, Y, Z, D, F, X_2Z_3, ... themselves. The interconnected and nested space of interiorities, for this reason, requires that decay operate as an instantaneous rate of change between different horizons of interiority or points of inflection. It is this ability to exteriorize a horizon of interiority via the relation – *viz.* nested interconnections – between exterior horizons which themselves are being exteriorized – and thus changing – that posits the process of decay as the blackening counterpart of the differential calculus. This is because differential calculus is a technique to determine and calculate the instantaneous rate of change between different uniformly or difformly changing variables. Just as Leibniz's solution for calculating the instantaneous rate of change between different changing variables involved the concept of infinitesimals, decay exteriorizes an object into its exterior backdrop through the limitropic shrinking of the object. For a decaying object, what is considered the exterior backdrop – as argued earlier – is a nested space of interiorities whose complicities do not allow the process of exteriorization to be vectorially unidirectional, structurally uncomplicated or, as a consequence, unproblematic. *The complicity between interiorities cannot be undone or decontracted in a simple fashion, for such complicity engenders differential fields which can only be exteriorized by the subtractive logic, chemical techniques and mathematical dynamism of decay as a building process and a model of complicity.* The political implications of decay as a model of complicity corresponding to the original ideas buried in differential calculus call for a thoroughgoing investigation into the calculus of decay.

• The differentially regressive plunge of decay into the depth of nested interiorities always finds an extensive echo in the form of differential reverberations of rot. There is no depthwise putrefaction or *nigredo* without the wriggling of worms on the surface and the mephitic extension of the rotting object into the air. Decay's intensive exteriorization of nested interiorities has an outward productive expression which is subtractively correlated to the blackening line that traverses the confines of nested interiorities. The more enveloped and interiorized the horizon, the more chemically productive its extension to the outside. It is as if the degree of interiorization – that is to say, the spatial confinement of the horizon and the amount of capital enveloped for sustenance and development – is directly proportional to the chemical fertility of the horizon when it begins to extend outside of its confines. Here, the degree of interiorization does not become an impeding factor for the extensive loosening of the horizon, but contributes to the differential extension of the horizon to the outside as well as the chemical – hence contingently dynamic – productivity of the horizon during decay. This illogical proportionality between the insistence on remaining interiorized and the spontaneous chemical loosening into the outside shares more with the laws of the grave than with the laws of nature – the putridly productive amalgamation of the restrictions of *nomos* and the confines of *taphos.* We argued that decay is neither wholly negative nor wholly positive; it is rather subtractive. The subtractive logic of decay suggests that decay does not merely build the nested horizons of interiorities as an intensive limitropic vector toward zero but that it also builds via extensive deployment of interiorities so as to create a dynamically contingent universe. Leibniz – following the proto-scientific ideas in the Middle Ages – frequently uses as an example the model of a rotting body (usually cheese) whose remaining perforated body suggests an intensive limitropic convergence upon zero. Yet this intensive movement in the interiority of the object, manifested as shrinkage, cannot exist without another opposite movement which extends the body into the outside in the form of contingently differentiated ideas or smaller bodies. At the same time as the apple shrivels, it spews forth worms as extensively deployed and hence dynamically contingent interiorities. These worms or derivatives in turn envelop smaller worms and further derivatives which contain yet smaller bodies *ad infinitum* … all ready to heave forth and be extensively deployed in the most contingent manners. This applied dynamics of contingency marks the rise of chemistry as a process commencing from within. The subtractive movement of decay's blackening line of exteriorization through nested horizons of interiority produces two functions: firstly, a limitropic convergence upon zero dubbed *complicatio* and formally expressed as progressive shrinkage; secondly, a differential extension or divergence from the object, called *explicatio* and expressed in the form of a dynamic and contingent process of productivity. *Complicatio* and *explicatio* are subtractively correlated, in such a way that the intensive interiority of *complicatio* contributes to the extensive deployment of interiorities in *explicatio*. The decaying idea, in this sense, not only undergoes a nested twist as it limitropically approaches the *zero of ideas*, but also a productive twist as it is subtracted to the outside. For this reason, decay's process of exteriorization is in complicity with interiorities and their differential fields on two levels: (1) the intensively enveloped – hence nested – interiority of the decaying idea or rotting object; (2) the extensively developed interiorities which are differentiated from the rotting object and whose contingent world points to a dynamic chemistry which enforces the irruptive contingencies of time mobilized through the involutions of space. To sum up, decay's line of exteriorization has, weirdly, a productive disposition which generates extensively and contingently distributed differential fields (or sites of chemical activity). The eruption of these explicated differential fields reinforces the necessity for a complicity between the process of exteriorization (*viz.* binding exteriority and inflection upon death) and horizons of interiority, whether as fundamental terrestrial formations or sociopolitical grounds and networks.

The three reasons enumerated above briefly explain the complications that the process of decay brings about for the idea of return to the origin, and for a philosophy based on the implications of binding extinction and decontraction into originary death. Yet they also diagram the spatial model in which the process of decay operates. In order to present a formalism of decay which provides us with a mathematical model for decay's dynamism, we must, in addition to decay's conception of space, examine decay's conception of time. For this reason, we shall inquire into decay's conception of time and how it is expressed by the spatial involutions generated by decay's line of exteriorization as it traverses nested interiorities.

MEMENTO TABERE: THE TERNARY CONCEPTION OF TIME, OR THE MISSING LINK OF CHEMISTRY

The process of decay has a spatial model comprised of intensive envelopment and extensive development, and whose subtractive correlation creates differential fields which are sites for the generation of abstract twists and deformities. In other words, these sites spatially narrate chemical activities potentiated by time's contingencies; activities whose irruption endows the spatial plot with a holey and porous underside. Chemistry, therefore, as applied dynamics wherein contingencies of time are extensively enforced by the involutions of space, requires a third conception of time whereby absolute contingencies of time can operate from within the interiority of a horizon. If putrefaction marks the beginning of chemistry, its subtractively-productive process needs such a conception of time so as to mobilise the contingencies of time as the chemical traces of those spatial involutions and envelopments which are asymptotic with the conceptless exteriority of space. This brings us to more fundamental questions concerning the role of time in any politics or philosophy incorporating decay as the building process of its formations or ideas: What is the relation of decay or putrefaction to time? Is decay a narrative conception of time's indifference to ontic differences, or is it the experience of time as presence which – in a Heideggerian fashion – turns death into an infinitely-deferred occurrence through *Dasein*'s already-dying? What exactly is the role of time in decay, and does this role reinscribe the correlationist appropriation of time through experience and presence, or amount to an idealism which favours and privileges time over space? And finally, if time is imbued with radical contingencies which suspend all affects and relationships through the indifference of time as an impenetrable alterity, then how can decay as a building process bring about the opportunities of complicity between the involutions of space and contingencies of time? It is evident that decay's conception of time, which emphasizes the role of time in the chemistry of decay, is so pivotal that it determines different conceptions of decay and putrefaction. Decay as a romanticized concept, decay as a necrocratic fetish, decay as a differential form of emptiness, decay as an *umwege* (maze) toward base-matter and decay as an ontological fate, are all decided by different conceptions of time, in itself and in its relation to space.

The chemical potency of putrefaction (*tabes*) which decomposes the object into other horizons of interiorities across infinite latitudes of forms, attests to the fact that there is a complicity between irruptive contingencies of time and spatial folds and inflections of space.

Through such complicity, the diachronicity of time and the exteriority of space are evinced by each other: Whilst space is perforated by time's emptiness or fundamental indifference, time's contingency is formally expressed by space's unbound ferocity for the assimilation of any ground of individuation. It is this collective fold of complicity – neither demanding a commonality between the parties involved nor the substitution of either of them by the other – that makes decay an unwholesome participation between the most abominable aspects of time (non-belonging and pure contingency) and the most degenerate aspects of space (space's tendency for infinite involutions which undermine any potential ground for the emergence of discrete entities). It is the complicity between the worst nightmares of space and time that brings about the possibility of putrefaction (even an infinite decay) as a differential form of irresolvable emptiness disguised as ideal objectivity with a generative twist. To think of this impregnable hollowness endowed with a generative proclivity, one can envisage an infinitely porous abomination, an obscene hollowness, folded and mobilised in such a way that it has an objectal grimace: The mediaeval *danse macabre* depiction of the Tree of Rot – a 'difformly difformly difformly difform'[5] (Nicole Oresme) tree trunk which spews forth a cosmic range of both familiar and nameless creatures as a differential extension of its arborescent emptiness.

The complicity between space and time – that is, between the dynamism of inflections and the irruption of contingencies – brings forth the possibility of chemistry as the concomitantly softening and loosening dynamism of putrefaction.

---

[5] See L. Thorndike, 'An Anonymous Treatise in Six Books on Metaphysics and Natural Philosophy', The Philosophical Review 40, no. 4, 1931: 317-40.

As the chemical space of decay, putrefaction exposes the object to the contingencies of time so as to thaw the object's ideal integrity and initiate its loosening into the conceptless involutions of space. In order to explicate the nature of this complicity as an intrinsic act for the chemical dynamism of putrefaction, first we must clarify the modes of complicity at work here. If time belongs to no one and is absolutely indifferent to ontic differences, then how can its worst nightmares participate with space? And if, notwithstanding such irresolvable incommensurability, time and space can indeed participate with each other, then how can this participation be conceived outside of the correlationist ambit? Our conjectural solution for these problems concerning a blackening complicity between space and time consists of two stages: In the first stage, our solution entails the implementation of two conceptions of time. On the basis of these two conceptions, we seek to bridge the exteriority or diachronicity of absolute time and the exteriority of space. This means that in addition to the absolute conception of time, an intermediary conception is also required. The intermediating time must be interconnected with the absolute conception of time (i.e. time as an indifferently impenetrable alterity that belongs to nothing and no one) as a manifestation of the latter's pure contingency. In other words, the intermediating conception of time should itself be a production of absolute time's pure contingency which suspends all natural laws, obstructs the operation of belonging and nullifies ontic differences. To put it differently, the intermediary conception of time should itself be a symptomatic production of absolute time's pure contingency. *Accordingly, the intermediating time does not suggest a dichotomous scission in time, but a temporal and contingent conception of its absolute form.* Only the vital temporality of this intermediating time can bring about the possibility of ontological difference in relation to appropriated regions (scales) of space.

Space-time syntheses – necessary to support ontological determination – require the bifurcation of Time into two different but interconnected conceptions. Without such a bifurcation, absolute time and thanatropic space remain inherently exterior to each other and cannot ground the conditions for ontological determination on any level. It was the Stoics who for the first time fully realised the necessity of having different conceptions of time with the aim of explaining the vital syntheses of time and space. In order to explain the intensive vitality of determination qua difference-in-itself, Deleuze adapts and ingeniously modifies the Stoic model so as to develop and employ two conceptions of time, the time of aîon and the time of chronos.[6] Since the indefinite non-pulsed time of aîon is inherently closed to vital bodies, there must be another conception of time capable of synthesizing with the scales of space and supporting vital vibrations. This second conception of time is the pulse-time of chronos, which supports organic vitalities and provides time with qualities compatible with the structure of corporeal beings. Accordingly, the first *already-established* stage of our solution requires the bifurcation of Time into two different but interconnected times. Following Deleuze, but in contrast to his quasi-Heideggerian reading of time, these two conceptions are reabsorbed in this fashion:

---

[6] See John Sellars, 'Aîon and Chronos: Deleuze and the Stoic Theory of Time', **Collapse III**, 177-205.

1. The ungraspable and cosmic time which belongs to nothing and no one. It is the absolute time of pure contingencies or cosmic climates which unilaterally suspends all laws and eliminates all necessities.

2. The temporal conception of time, which is time insofar as we experience it and which, therefore, is characterised by the access to its presence rather than its quiddity *per se*. Yet, even more importantly, the temporal conception of time supports the temporality of beings by providing the conditions for their ontological determination and emergence. These conditions are nothing but the contingencies of the cosmic and absolute time. The temporal conception of time, accordingly, envelops and foregrounds contingencies of absolute time in the form of conditions for the emergence of life (or the subject of temporality). Therefore, the temporal conception of time is an interiorized or bounded form of absolute time, a temporal set wherein contingencies are taken as conditions for the determination and the continuation qua temporality of existence. In other words, temporal time posits the contingencies of absolute time as the ground for the determination of difference and ontic emergence, through a bracketing and interiorizing of those pure contingencies. We call this temporal conception of time, vital time or the time of determinations and making differences. Constitutive to the ground of life, vital time is accentuated in the organic realm through the compatibility of its interiorized and sequential structure with the sequential growth or the rhythmic difference of organic interiority. In other words,

> the interiorized contingencies of vital time become structurally compatible with the involutions or interiorized horizons of space. Without such basic structural compatibility between space and time – albeit at the cost of their envelopment and interiorization – ontological determination and the emergence of ontic differences which are tied to space-time syntheses are impossible.

Vital time – the intermediary conception of time – emerges from the cosmic time of pure contingencies as ‘an interiorized set of contingencies’. As a temporal set, vital time interiorizes contingencies as its elements. Since the function of the set is interiorization, it can intensively determine the contingencies of absolute time as conditions for the emergence of life, or as necessities for making difference. In the process of interiorizing contingencies and realizing them as concomitantly temporal and necessary conditions, vital time appropriates the exteriority of cosmic time and turns it into an interiorized conception of time accessible by life and its manifestations. Yet the cosmic time of non-belonging and pure contingencies can never be fully appropriated or assimilated (interiorized) by vital time and its temporal conception. This is because vital time is itself contingent upon cosmic time as a *temporal condition* for the interiorization and bracketing of absolute time’s contingencies and their realisation as the conditions required for the emergence of life. This means that since vital time is itself a temporal condition *qua contingency* of cosmic time, it cannot fully interiorize the exteriority of absolute time qua pure contingencies. Vital time suggests only one of the infinite pure contingencies of absolute time; its fundamental functions are simultaneously supported and derailed by other contingencies. For this reason, contingencies of cosmic time are never fully reintegrated and absorbed within the manifestations of life (viz. realised horizons of interiority) conditioned by vital time. To put it differently, vital time can be interiorized by beings as the necessary condition for their emergence because it is itself an interiorized conception of cosmic time's pure contingency. This brings us to another problem which constitutes the second stage of our conjectural solution to the problem of complicity between space and time necessary for the chemical dynamism of putrefaction.

If cosmic time can never fully be appropriated by and within vital time, then the horizons of interiority inherent to manifestations of life or ontic differences cannot assimilate and appropriate the contingencies of cosmic time either. Consequently, the interiority of life is a host or a niche for the inassimilable contingencies of cosmic time – contingencies that never completely turned into temporal conditions within vital time but remained part of the unilateral ecology of the cosmic abyss within vital time's temporal set. Briefly, vital time interiorizes contingencies of the cosmic abyss in order to form its temporality; however, there are still contingencies of cosmic time which, despite being interiorized, defy assimilation by the laws of the temporal set that turns contingencies into vital conditions. These interiorized yet inassimilable contingencies, consequently, implement the unilateral ecology of the cosmic abyss from within vital time and consequently, from within an interiorized horizon such as the organism or the planet. In conditioning the emergence of life, vital time introduces the nightmares of cosmic time into the phenomena of life. The horizon of interiority inherent to the manifestations of life becomes an incubating chamber for the pure contingencies and non-belonging of cosmic time. It is this non-belonging qua principle of negativity that is mobilized by the dynamism intrinsic to involutions of space. The subtractive process of decay is the outcome of such spatial mobilisation whereby the unilaterality of cosmic time underpinned by its irruptive contingencies gains a subtractive – that is, extensively positive and intensively negative – momentum through inflections of space. As an outcome of its complicity with space, time's unilateral negativity is imposed on the horizon of interiority in a way that forces the horizon to be concurrently swept away along the extensity of space and intensively shattered on zero qua the eternal.

Thus cosmic time is deployed inside vital time and, correspondingly, inside the life or the horizon of interiority that is conditioned by vital time. This remobilisation of cosmic time's exteriority and redeployment of its contingencies within vital time and manifestations of life posits a third conception of time which constitutes the second stage of our conjectural solution. The blackening complicity between space and time can only be fully explained via recourse to a third conception of time which is always implicit – as an internal tension – to the dyadic conception of time. We call the third conception of time, the *insider conception of cosmic time*. It is conceived of as a treacherous insider insofar as it internalizes the complicity between time's diachronicity and the exteriority of space within the manifestations of life and the horizons of interiority. The conception of cosmic time as the insider redefines the intermediary conception of vital time as a 'temporal agent' that brings with it into life's horizons of interiority the contingencies and non-belonging of cosmic time. In other words, the insider conception of cosmic time interiorizes and cultivates the incommensurable tensions between cosmic contingencies within life and its manifestations – thereby giving cosmic ecology an eruptive (i.e. volcanically extrusive) expression rather than an intrusive insinuation.

In the wake of the insider conception of time, the termination of life does not *exclusively* mark the temporality of life qua its contingency, because the very interiority of life (its difference and internal vitality) can unfold as the abyssal infinity of material and ontological contingencies whose irruption is equal to death. This unfolding of cosmic time's pure contingency through life and by life is expressed by decay as a dysteleological process. In this sense, life's interiority is a medium for the cultivation of incommensurable tensions between the contingencies of cosmic time. And decay is the germinally-cultivated expression of these incommensurable tensions or contingencies along infinite involutions of space – a complicity between time's subtractive enmity to belonging and the enthusiasm of space for dissolution of any ground for individuation, a participation between cosmic time's pure contingency and the infinite involutions of space from whose traps nothing can escape.

The process of putrefaction or decay accentuates the compulsion to return toward pure contingencies of cosmic time through the third conception of time (i.e. cosmic time as insider time). This so-called 'compulsion to return' instigated by the insider conception of time becomes a source of tension between the principles of cosmic time (i.e. contingency and non-belonging) and the temporal conditions or necessities of vital time. These contingent and subtractive tensions are narrated by the degenerate qualities of space through the process of decay in the form of a progressive softening of forms and loosening of the horizon. We can say that in decay space is perforated by time: Although time hollows out space, it is space that gives time a twist that abnegates the privilege of time over space and expresses the irrepressible contingencies of absolute time through dynamic and formal means. This in-flective mobilisation of cosmic time's radical contingencies heralds the birth of chemistry as the blackening complicity between time and space. It is chemistry that endows the subtractive process of decay with a putridly productive nature.

FIGURING OUT THE FACE OF ROT, OR IDENTITY AND THE FORMS OF BEING LESS THAN A THING, MORE THAN NOTHING

The subtractive dynamism of decay is generated on the basis of a complicity between space and time which allows for the chemical loosening of the horizon of interiority along nested inflections that are simultaneously extensive and intensive to the horizon. The dynamism of decay utilizes the complicity between space and time as the principle for an unconstrained deformability where loosening and softening – the lytic functions of chemistry and the smoothing functions of differential calculus, i.e. mathesis – are intertwined and unbound. Yet such unconstrained deformability is translated, as elaborated above, into the intensive complicity of nested interiorities as well as the complicity of interiorities in their extensive deployment. Through these intensive and extensive planes of complicity, interiorized horizons asymptotically bind the exteriority of space and the diachronicity of time.

The asymptotic binding of exteriority requires an interpolating dynamism capable of traversing all interiorities complicit in the process of exteriorization as changing variables whose ratio must be calculated. To put it differently, since interiorities are always in complicity with each other, the process of exteriorization must find a way, firstly, to grasp interiorities in terms of their complicities; and secondly, to conduct exteriorization based on the dynamic factors, elements and variables brought about by such complicities. Exteriorization is not possible without factoring in and acting upon the complicities between interiorized horizons. Yet acting upon such complicities – characterized by dynamic relationships and rates of change between horizons of interiority – requires a solution reminiscent of differential calculus, a solution capable of calculating the instantaneous rate of change between changing variables.

The solution of decay's process of exteriorization for the problem of changing and complicit interiorities/variables is the limitropic decomposition of the object or formation. Only though the limitropic movement of the object or formation toward zero (whether as the conceptless exteriority of space or the diachronic eternality of time), can the process of exteriorization cut through the complicity between interiorities which is too differentially convoluted to be disentangled or decontracted through regressive thanatropic movement. The limitropic wasting or subtraction of the object (or formation) along its extensive and intensive vectors does not allow for the complete eradication of the object's ontological registers, structural fundaments or operating axioms. The effect of such limitropic wastage, in which the formation is loosened and softened to no end yet leaves traces which linger as the agents and particles of complicity, has a strong socio-political undertone. Even after a political formation turns into an unrecognizable corpse, where all of its structural and operative influences have presumably vanished, there still remain active structural fundaments and functional axioms from that formation without whose complicity the political calculus of world politics cannot possibly be formed. For, once again, in decay the relationship or change between horizons of interiorities (as entities intrinsically susceptible to decay) is possible only through limitropic deterioration toward a *zero of interiority*. The limitropic deterioration brings about the possibility of the differential interpolation of the decaying horizon between other interiorized horizons and, as a result, instigates the construction of a universal calculus of putrefaction. It is this limitropic deterioration that introduces the lingering and persistent axiomatic remnants of the decaying formation to an unsuspecting *uni-versal* calculus, as minute but ineradicable agents of complicity.

Neither fully negating the system by overthrowing it nor reaffirming it through reformation, the process of decay imposes a perpetual deformability on the formation without completely erasing its ontological registers and functional axioms. In short, decay extracts infinite deformability from an interiorized horizon without eventuating in radical erasure or complete transformation. Such perpetual deformability is supported by the intensive and extensive complicity of horizons of interiorities in the form of an unbreakable continuity in which every horizon of interiority either inflects the next or is nested within yet another horizon. Accordingly, it is the ceaseless continuity – in the sense of intensive and extensive inflections of forms and interiorities – that imparts a fluid continuity to the rotting object without essentially turning it into fluid. Each form is only *gradationally* preceded and succeeded by other forms in such a way that transition along latitudes (of forms) is always blurred. The gradients of deformities are differentially smooth, to the extent that the formal dynamism of rot appears to be that of sludge or oozing flesh. In decay, the solid undergoes a flowing series of deformations without becoming liquid, or in other words, without losing its basic principles of solidity. The wholeness or coherency of the solid is derailed within the fundamental principles of solidity. In a similar fashion, in putrefaction the liquid's degeneration vacillates between solid and gas, slime or miasma, but in either case it remains fundamentally – albeit minimally – liquid. This minimum body of the element, horizon, formation or object, in fact suggests its concomitant asymptotic exteriorization and limitropic diminution. Recall Bishop Berkeley's sneering deprecation of infinitesimal calculus as dealing with the 'ghosts of departed quantities';[7] the decaying object, indeed, is an evanescent yet lingering ontological register that is less than a thing but more than nothing.

Supported by the complicity of interiorities, the continuity of forms or the gradients of deformability ensure that the interiorized horizon is always formalized as a fluxion of contingent and even inconsistent forms. It is actually in decay that inconsistent forms are smoothly connected to each other so as to form a congruous plane of deformability in which becoming does not essentially follow the logic of the affect but rather the logic of putrefaction and its method of exteriorization. Victor Hugo concisely epitomizes this fluxional connection of inconsistent forms, ideas and entities in putrefaction in *Les Misérables*: 'In a pit of slime [...] the dying man does not know whether he has become a ghost or a toad.'[8] It is only in putrefaction that death is essentially and weirdly non-hauntological: one becomes a toad rather than a poltergeist annoyingly clamouring for appropriate mourning, for a proper judgment or a spectral solution. Whilst in putrefaction the human might end up as a toad, the toad itself grows a tail. The tail, in this case, speaks to the differential idea or latitudes of form between a toad and a tadpole, the mathemathico-chemical affect between them, the ratio of putrefaction: the longer the tail, the fouler the putrefaction:

---

[7] G. Berkeley, *The analyst; or, A discourse addressed to an infidel mathematician* (1754), 59.

> It was observed in the great plague of the last year, that there were seen, in divers ditches and low grounds about London, many toads that had tails two or three inches long at the least; whereas toads (usually) have no tails at all. Which argueth a great disposition to putrefaction in the soil and air. It is reported likewise, that roots (such as carrots and parsnips) are more sweet and luscious in infectious years than in other years. [...] So the parts of beasts putrefied (as castoreum and musk, which extreme subtile parts,) are to be placed amongst them. We see also that putrefactions of plants (as agaric and Jew's-ear) are of greatest virtue. The cause is, for that putrefaction is the subtilest of all motions in the parts of bodies; and since we cannot take down the lives of living creatures, (which some of the Paracelsians say, if they could be taken down, would make us immortal,) the next is for subtilty of operation, to take bodies putrefied; such as may be safely taken.[9]

Putrefaction is comprised of these extremely subtle motions – infinitesimal fields of differentiation – according to which various and outlandishly incongruous forms can smoothly blend. The idea of the human becomes a smooth gradient of different worms, flies, wasps, plants and fungi. The toad, the miasma, the sludge and the human all become part of a differential field wherein each entity can gradually unfold into another regardless of the congruity of their traits, environments and habits. These subtle, fluxional or infinitesimal movements point to the gradational continuity of deformities in decay whose basal continuity is maintained by the dynamism of complicity as a form of participation in which, instead of commonality and replacement, inflection and nestedness – that is to say, the mathesis of the insider – are the guarantors of the collective action. To this extent, a politics of decay as building process fully employs the mathesis of the insider as the prerequisite for the dynamism of collectivity: In the calculus of decay, it no longer matters if there is a commonality or even a minimal agreement between conjoined or discrete elements; putrefaction causes the decaying or infected parts or elements to interpolate themselves between other healthy elements and parts in such a way that everything is collectively mobilised by and toward putrefaction.

[8] V. Hugo, *Les Misérables* (London: Penguin, 1982), 1087.

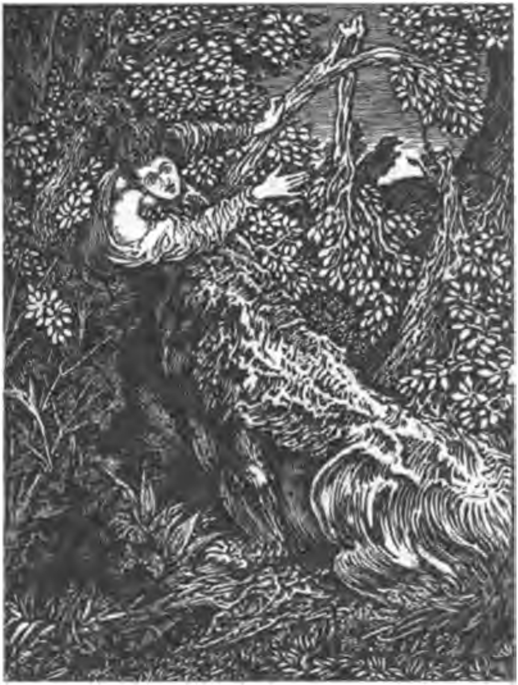
[9] F. Bacon, *The Works of Lord Bacon* (London: Henry G. Bohn, 1854), 159.

The fluxional continuity of decay gradients smoothly, or more accurately, differentially connects incongruous forms. The act of figuration, in terms of decay, is equal to smoothing what is already out of place; everything must be con-figured again according to the smooth gradients of decay whose basal continuity lies in the complicity of horizons of interiority. To putrefy means to 'parabolify the straight line' (to use Boscovich's term),[10] then to twist the curve and eventually to convolute the already twisted curve. In other words, in order to approximate forms, the line of figuration must pass through points of inflections or latitudes of a given form. In this sense, figuration becomes more accurate as it passes more points of inflection or traverses more latitudes; yet to encompass more points means that the line of figuration cannot remain a straight line but must become an increasingly convoluted curve. The painter Francis Bacon presents such a model of smooth figuration in which a form is limitropically approximated through ever swirling and twisting curves. Bacon's method of figuration becomes a function of approximation rather than reproduction and for this reason, it acquires a configuring mechanism that corresponds intimately to that of decay and its smooth gradients: How many points can a line encompass, how many latitudes can be traversed by a differential function, before the line turns into a coiling abomination or the differential function becomes 'difformly difformly … difformly difform'? The thawing meat of Francis Bacon's figures, the oozing colour gradients of his landscapes and the heads whose figural approximations are bundles of coiling tails all suggest a differential function which indexes instant and remote derivatives of a given form in the smoothest fluxional manner.

---

[10] J. F. Scott, 'Boscovich's Mathematics' in *Roger Joseph Boscovich, S.J., F.R.S., 1711-1787: Studies of His Life and Work on the 250th Anniversary of His Birth* (London: George Allen & Unwin Ltd., 1961), 183-92.

In decay, the act of figuration corresponds to the act of curve fitting in interpolation. Between two forms, two entities or two horizons, one can only make a continuously smooth connection by encompassing the derivatives which remotely connect these forms or entities together. The remoter and further apart the derivatives of these forms and entities, the smoother and more congruously they can be connected to each other. As the forms or given variables increase, the differential function also becomes more complex and the curve for smoothly connecting these variables or given data points becomes increasingly more convoluted. A curious literal depiction of these seething differential curves which connect putrefying forms together in the slimiest and most twisted ways possible can be found in Laurence Housman's intricate art nouveau drawings. *Cauchemar* (which originally appeared in *The Dome*, published by Unicorn Press [1899]) is a nightmare of a slimy nature lost and perplexed in the putrid mazes of its evanescent forms and their derivatives. It depicts a man being consumed by trees, becoming a tree,



yet this concomitant change of identity and forms leaves behind it a slimy trace, demonstrated by a pandemonium of twirling curves which connect the horizon of man to that of trees.

The universal calculus of decay does not tolerate an abrupt mutation from human to tree, as Hieronymus Bosch's tree-man might imply. In decay as a process of cosmogenesis, the tree and human are not two entelechies or perfected bodies of actuality which can be connected together via a straight line. Both 'being a tree' and 'being a man' are changing variables – rates of change between their respective actualities and potencies on the one hand and between their interiorities and the exteriority on the other. Therefore, the most veritable line of transition that can be drawn between a human and a tree is not a line connecting their fixed actualities or traits but a line that encompasses their existing actualities (given points) as well as their potentials and derivatives (even the remotest ones). The tree is itself a differential field of ideas – or in a Leibnizian sense a generative reservoir of smaller bodies – which themselves are changing and have their own derivatives; the same profusion with subtle bodies and movements is also applicable to man, its idea and its form. Therefore, in order for the line of putrefaction to draw gradients of decay between the man and the tree, it must encompass such ever-increasing (both in quantity and distance from their original ideas or formations as a whole) emerging bodies, ideas or derivatives. In interpolating between all these points and emerging values, the slimy line of rot becomes an ever-convoluting curve. For this reason, the nightmarish plunge of the human into the verdant inferno of growth is accentuated when the line between the human and the tree becomes infinitely convoluted, encompassing a cosmic array of beings which only differentially – that is to say, very remotely – connect to either the tree or the human. In other words, in decay, the object travels across a world of familiar and alien beings which may or may not have any immediate relationship or affinity with the decaying object. This also means that the most accurate line of transition between a human and a tree is a line that progressively encompasses not only the tree and the human but also their remotest derivatives and the least actual potencies. This is the taphonomic logic behind the slimy forms of putrefaction and the ever-shrinking bodies of decomposition (as in ruins) where the complicity between parts and derivatives becomes a subtractive and hence synergistic counterpart to the limitropically shrinking remnants of the thing's former self. In becoming a vividly accurate (i.e. nightmarish) transition between the human and the tree, the connecting line encompasses more beings and consequently becomes more convoluted. Decay corresponds to such an approximation of the distance or relationship between two given entities as continuously-changing variables. The minimum possible number of curves for passing through the maximum number of points or entities – this flawed but concise formula defines the nightmare of decay as an abominable curve that extracts values and beings from all that it encompasses, building worlds and corpses more efficiently than God. The effect of decay's cosmogenesis for any horizon of interiority is a weird amalgamation of vitalistic trust in one's survival and susceptibility to a unilateral terror from the inside – the treachery of the former and the non-negotiability of the latter. This is not just because decay draws its lurid forms upon the complicity of contingencies of an indifferent time with the conceptless exteriority of space, but because it mobilises the exteriorizing terror of such complicity right from the inside of the interiorized horizon and through its locus of persistence and its definition of survival.

BUILDING WORLDS AND CORPSES, OR THE QUESTION OF MATHEMATICO-CHEMICAL DYNAMISM

> I observe in advance that numerically the same change may be the generation of one being and the alteration of another: for example, since we know that putrefaction consists in little worms invisible to the naked eye, any putrid infection is an alteration of man, a generation of the worm.[11]

It was argued that decay effectuates a perpetual deformation which does not dismantle the primal formation by erasing its fundamental ontological registers or minimal formal traits, but rather ceaselessly pushes the formation to new levels of degeneration by infinitely building over and through it. For this reason, decay can extract softness from solidity (if solidity is inextricable from its stable, molar and rigid qualities as well as its manifest wholeness) and its socio-political abstractions, deducing political tenacity and persistence from the degeneration of power formations. This is the arcane *modus vivendi* of certain political systems whose decay or corruption does not lead to their demise and destruction but rather endows them with the gift of a camouflaged existence – a simultaneous unrecognizability ensued by thawing forms and an axiomatic or fundamental persistence as the result of their limitropic dissolution. Once the state embraces decay as a form of camouflage and persistence, it turns into a site of complicity between all decaying elements or splinters of rot in its vicinity, in the manner of an interpolating differential function. The nebulous term 'rouge state' outlines some of the characteristics of a state which has deliberately bound decay as the building process of its formation. It is in this sense, that the degeneration of the solid and its abstractions does not essentially entail its dissolution into liquid or the fluid state where the solid loses its minimal traits through fundamental transformation, but the differential deformity of the solid to such an extent that the idea and formal integrity of solidity are chemically pulverised by the inner potencies of the solid itself. The solid gains a corrupting mobility – or a differential power of interpolation – at the cost of losing its integrity and established forms. The impaired integrity of the solid formation allows for the eruption of potencies whose actualisation would otherwise have been subjected to the pre-established laws and climates of solidity (viz. its coherence, formal rigidity, stability, etc.)

---

[11] G. W. Leibniz, *Philosophical Papers and Letters* (Dordrecht: Kluwer Academic Publishers, 1989), 96.

The forms of rot, as discussed in the previous section, are in direct correspondence with the dynamism of decay or its differentially corruptive mobility. Since the complicity of time and space in their contingency and exteriority bring about the possibility of this peculiar dynamism, the dynamism of decay is characterized by a chemical disposition with a calculative mode of distribution. Whereas its chemical disposition is associated with the spatially enveloped and mobilised contingencies of time, its calculative mode of distribution is the result of its asymptotic approach to the exteriority of space according to which every interiority inflects yet another interiority, whether in the direction of the precursor exteriority (*complicatio*) or the extensively dissipated interiorities (*explicatio*). This chemically-charged and calculative dynamism, accordingly, operates as a bidirectional building process: it intensively builds the abstract by positively binding a limitropic conception of zero (the body of the minimum) and extensively builds the concrete by extensively giving rise to derivatives or differentiated horizons of interiority (worms, animalcules, ontic differences). In order to formalise the dynamism of decay as a building process, a reductionist mathematical formula of decay can be constructed so as to demonstrate, capture and ultimately diagram decay as a building process. This reductionist formal model incorporates three basic interconnected aspects of decay's dynamism:

> (1) Perpetual inclusion – inflection and nestedness: The line of decay or the differential function of putrefaction must cover and encompass all given values – given points, forms and traits of the interiorized horizon as well as its emerging derivatives, actualities and gradationally emerging potencies. Perpetual inclusion ensures that all emerging potencies be indexed and encompassed by the differential function of decay. Any change – whether extensive or intensive, outward or inward – in the decaying object should be included by the process of decay. The possibility of including and encompassing both intensive and extensive changes attests to the imperfectibility of being and the inherent susceptibility of the interiorized horizon to exteriorization. Since perpetual inclusion means that both extensive and intensive changes are encompassed concurrently and since these changes are subtractively correlated to each, the perpetual inclusion is essentially the ratio of changes which registers itself

as a slope – the rate of ex-plicatio (unfolding) to complicatio (folding), extensive motions to intensive motions, $\frac{\Delta y}{\Delta x}$.

(2) The law of basal continuity, or the persistent continuity between limitropically vanishing values and emerging values: In a decaying object, no matter how significant the change or how unrecognizable the deformity is, it cannot depart from the ever-shrinking fundaments, axioms or basic registers of the object or formation. In other words, as the formation undergoes new extremes of deformity or the object rots to new levels, the fundaments of the formation or the basic ontological registers of the object also become more emphatic – that is to say, truer to their ideal. The law of basal continuity in decay holds that emerging values or changes must be continuous to fixed or established values, fundaments and basic axioms of the formation regardless of their distance and difference. Here continuity can be formalised as follows: Suppose X is a fundament or an axiomatic value of a decaying system and Y is a deformation, a change or an emerging value, and the function f stands for the putrefying line of decay that encompasses X and Y. Now, f is continuous at x for some $x \in X$ if for any neighborhood W of $f(x)$, there is a neighbourhood Z of x such that $f(Z) \subseteq W$; meaning that, irrespective of how small W becomes, a Z containing x that will map inside it can be found. If f is continuous at every $x \in X$, then f is continuous.

(3) Differentiable smoothness: Following and in accordance with the first two principles, the encompassing process of decay as an interpolant should be as smooth as possible, or more precisely, infinitely differentiable so as to support both the perpetual inclusion of all extensive and intensive changes and the basal continuity between persistent remnants and emerging forms and values.

In decay what is firstly enacted is the subtractive power of putrefaction whereby extensive and intensive changes are simultaneously included. Subtractive binding of changes ensures that vectorially opposite changes can be included in regard to each other in such a way that every extensive change inflects an intensive change and vice versa. For this reason, the law of basal continuity which emphasises the continuity between ever-shrinking fundaments and the emerging changes cannot be maintained except through the subtractive power of decay, or more accurately, decay's perpetual inclusion of changes and deformities. Therefore, perpetual inclusion enacted by the subtractive logic of decay precedes the continuity between the intensive ideals of the formation and its extensive ideas which are in the process of unfolding. In this sense, continuity C is built upon the output of inclusion I (i.e. inclusion of both intensive and extensive changes). Inclusion alone, however, does not support the continuity of what is included either in terms of 'the continuity between those changes which will be included and those which have already been included' (the intensively enveloped fundaments) or in terms of 'the ceaseless differentiability of the process'. For this reason, the input of continuity should be the output of inclusion, which is the sum of the actualities of the interiorized horizon and its gradient of potencies, the extensive development and the intensive envelopment of the formation. Here, if *I* is the perpetual inclusion and *C* the basal continuity, then their relation can be formalized as:

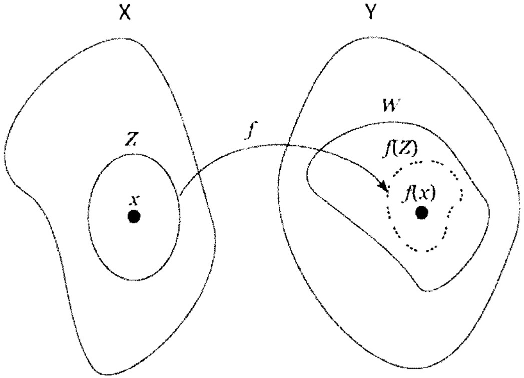


Diagram 1. Basal continuity between the limitropically shrinking object (persistence) and its putrid deformity (change)

$C \circ I$ or $x \mapsto C(I(x))$

Perpetual inclusion *I*, basal continuity *C* and differentiable smoothness constitute the main principles of decay's dynamism *D* in regard to any interiorized horizon *H* and in relation to time *t*. These three principles give decay the power to mobilise and unleash the irruptive contingencies of time from within and through the interiorized horizon.

Putrid deformities or smooth gradients of decay are forcefully yet nonviolently extracted from the ostensibly secured interiority of the horizon by the combined function of the aforementioned principles. Accordingly, for an interiorized horizon demarcated by the ratio of its actualities (*a*) and potencies (*p*), decay can be reductively symbolized as:[12]

$$D = H\int_{p}^{a}\left|\frac{(C(I(x)))^{n}}{t}\right| dt$$

The Leibnizian notation for the differentiation $(C(I(x)))^n$ would be $\frac{d^n(C(I(x)))}{dx^n}$ expressed as a rate of differentiation within itself – a differential curve within a curve. To put it differently, in the above formalised model of decay's dynamism, the process of decay D evolves not only as a curve generated by the complicity of time and space but also as a curve that differentially encompasses the potencies and actualities of a horizon. Decay, in this sense, is a curve in the perpetual act of curving. The act of perpetual curving whereby for every twist another twist is reinvented (*cyma reversa*) presents (reductively) a model of decay as a building process that delivers the interiorized horizon to its heretical wastelands. In line with Leibniz's remarks cited at the beginning of this section regarding the dynamics of infinitesimal vermiculation of the body in putrefaction, the process of decay returns every outward twist developed from the interiorized horizon with an inner twist within the horizon itself and vice versa. The reason (*ratio*) according to which the horizon of interiority works and strives for its ideal status takes a vermiculate turn once it is bent from both ends by the twists (abstract worms) which force it to veer in unforeseeable directions. Once a rectifying ratio between the ideal and the idea (both in its intensive envelopment and extensive development) is established, reason becomes a worm that bores through the horizon so as to prepare it for that which can easily creep in or ooze out. By differentially corrupting the ratio between the idea and its ideal and the ratio between actualities and potencies of an object, decay reinvents the interiorized horizon on the heretical side of itself. It is the pragmatic artistry of decay to harvest limitless potentialities from the subversive logic of interiority on behalf of an exteriority in whose term every horizon must be deserted according to a reason (*ratio*) which is crooked at both ends.

---

[12] The vertical bars here signify the absolute value of decay's dynamism D, both in its negative and positive orientations. Schematically, by positive decay we mean the extensive vector of decay which takes the idea toward its concrete chemical manifestations and unfolds the forms or derivatives which are enveloped by the interiorized horizon. By negative decay, on the other hand, we point to the intensive vector of decay which limitropically abstracts and shrinks the idea toward the zero of ideas and inflects the interiorized horizon toward the precursor exteriority.

Nowhere has the curving function of decay been more explored than in scholasticism – in particular in the theories developed at Merton College, Oxford and the University of Paris, which constitute some of the germinal ideas of mathematics and chemistry. In scholasticism, *mortificatio*, *nigredo* and *putrefactio* all point to the overlapping regions between chemistry and mathematics through proto-scientific ideas germinated in theology, natural philosophy, medicine and the culinary arts. The corpse, as the epitome of putrefaction, demarcates the transition from the *complicatio* of a body to its *explicatio*. Such transition essentially takes place as a slope, 'the rise of potentialities in the form of actualities' in respect to 'the varying flux of potentialities'. These are the slopes of body qua *complexus* that provide the process of decay with fields of gradation whose dynamism can only be differentially grasped. Unlike the *complicatio* of God, the *complicatio* of body qua *complexus* is under the influence of its actualities whose distribution is extensively toward the outer world or the world of multitudes. In other words, since the actualities of the body are not perfect (immutable), nor are its potencies fixed, the *complexus* of the body is determined by the ratio of *complicatio* (envelopment of potencies) and *explicatio* (the development of potencies as actualities) in regard to each other ($\frac{\Delta p}{\Delta a}$). For God, there is no rate of change (slope) between possibilities and actualities, since God is the complete actuation of its complete potencies or *Possest* (Nicholas of Cusa). Accordingly, if there is no rate of change between possibilities (Δp) and actualities (Δa) in God, or in other words, if God is not ontologically differentiable within itself, then $\frac{\Delta p}{\Delta a}$ cannot have a rate of change or slope, i.e. $\frac{\Delta p}{\Delta a}$ must be a vertical line (illustrated by the vertical fold *ap* in diagram 2). It is the verticality of God in the scholastic threefold of existence that precludes deviation, the emergence of gradients and consequently, the curving dynamism of rot – God is the one without slopes. Hence the saying, God is too stiff to rot.

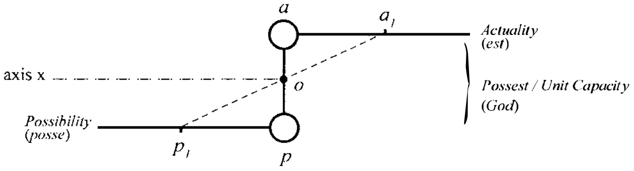

Diagram 2. The scholastic threefold of existence (*posse, est* and God qua *possest*)

For the scholastic marriage of mathematics and chemistry through natural philosophy, the *complicatio* of body is full of deviations, rates of changes between actualities and possibilities, little slopes everywhere swerving from the vertical positioning of *possest*. Twisting in and out, wiggling in all directions, slopes are bodies, disturbances in existence for which infinite differentiation is assured. Scholastic bodies are slopes or rates of change between the rise of actualities and potencies capable of being actualized ($a_1 p_1$). Despite their tangency to God, they possess the power of infinite differentiability, the power of prolonging the slope process – dragging the rate of progression and change between potency and actuality forever. But at any given time, for scholastic bodies, $\Delta p \succ \Delta a$ and $\Delta p \neq \Delta a$ otherwise the body is supplanted by the full body of entelechies whose possibilities have all been actualised. That is to say, if actualities become equal to possibilities or possibilities (all variations of *posse*) become exhausted by being actualised, then the scholastic body becomes a rival for the Divine or is posed as a blasphemous threat to its *possest* where $a=p$. The perfection of God is assured by uniting (or completely overlapping) the latitude of both potencies and actualities with the distance or the longitude between them. The impermeable infinity of God cannot express the world outside of itself; because outside of it is the field of slopes which expresses everything in the language of complicities, differentiations and ratios, rises over runs, the worlds produced by the undulations of imperfectibility – the cosmogenesis of decay. For scholastic bodies whose potentialities are infinite, their actualities can be neither infinite (as opposed to the infinite *entelechia* of God) nor equal to possibilities/potencies as in the case of the *possest* of God (i.e. $\Delta p \succ \Delta a$, $a \neq \infty$, $a \neq p$). Consequently, in this case, as actualities are fulfilled, their number in respect to potencies (possibilities) starts to decrease. In other words, the increase in fulfillment of actualities or perfections is equal to the decrease in actualities' capacity for differentiability. Therefore, for scholastic bodies, which are tangential to God's *possest* ($a=p$), being is $\lim_{\Delta a \to 0} \frac{\Delta p}{\Delta a}$ – that is, an open quandary in regard to infinity.[13] However, even if the potentialities/possibilities of being are not limitless (as some scholastic theologians like Anselm of Canterbury might object), the scholastic body is still an anomalous tangency to the Divine that instigates an 'infinitesimal subversion' against God: $\lim_{\Delta a \to 0} \frac{\Delta p}{\Delta a}$. Therefore, in either case, bodies of scholasticism are insurgencies or insistent perversions mobilized by slopes. In taking all beings as tangential to the *possest* of God, being can only be conceived in terms of rates of differentiation. The consequence of the onto-theological marginalisation of scholastic bodies via the privileging of God's *possest* is that the exclusive power and use of slopes is inadvertently dedicated to beings; this power is the power of extracting worlds through differentiation, or unearthing schemas of subversions through the limits of ratios. Everything other than God is the *explicatio* of slopes (Athanasius Kircher's abstract worms); this is far too cosmically revolutionary to be fathomed. Such is the revolution of scholasticism, flourishing in the mediaeval orgy of scholastic theology, natural philosophy and science.

---

[13] The anachronistic use of the limit function here is solely for a succinct exposition of the quandaries spontaneously generated in scholasticism as the result of marginalising the *explicatio* of beings. These quandaries or ideas, as implied in this essay, began to haunt mediaeval philosophy, and initiated a series of philosophical and scientific problems heralding and eventually leading to the rise of Renaissance philosophy and science.

Corresponding to the subtractive logic of decay, the ratios or slopes of putrefaction ramify the mathematico-chemical vectors of decay in two directions. This results in the architecture of decay being posited as a turning point (inflection) at which the concrete manifestation of the process of decay is chemically invested as the product of its abstract process, and the abstraction of decay mathematically returns to its concrete investment. The double-dealing attitude of decay in regard to the concepts of the abstract and the concrete contributes to the twist of decay as a building process: That which is palpably rotting develops out of that which is progressively becoming abstract. To put it succinctly, the process of decay is progressively concrete and retrogressively abstract. This return between the abstract and the concrete is especially evident in ruins, where the abstract is inextricable from the concrete; to privilege one over another is either a necromantic fallacy or a necrocratic policy.

Mathematics with a chemical disposition or chemical revolution via mathematical distributions, decay captures both within its act of building. It is only in the light of the mathematical and chemical complications of decay as a building process that the melancholic admiration for decay and fetid entities, along with the ostracization and dismissal of socio-political decay, can be dissected without blind romanticism, moral opprobrium or crude judgment. It is not that earthly thought is the site of decay from which we must ascend to the fresh air, but that the calculus of decay constitutes the ecology of our interiorized worlds – whether built on the desolate surface of the earth or in the fresh air of a beyond. The calculus of decay has its own problems, ideas and solutions; to politicise, philosophise, scheme or take action without such calculus is tantamount to calculating out of this world – an outside that does not suggest the great abyssal outdoors but the sealed enclosures of pure entelechy whose immutable horizon does not welcome ecological changes in any direction whatsoever.

Philosophers' Islands[1]

Robin Mackay

Theoretical physics and cosmology over the last half century has provided a new context in which some of the most fundamental questions of philosophy find a new life and a new sense. In this new context, we find the recurrence of an image that spans the history of Western philosophy: that of the island.

If we think of the fundamental parameters that govern the laws of physics as the axes of a topographical space, a landscape of possible universes, then to our best knowledge, only a very small area of it is 'habitable' by life: We live on an island – or rather, life as we know it is itself an island. Of course this does not mean that the universe was 'designed for us': Rather, it opens up the question of whether there might be other 'islands' in this space, other possible universes in which radically different forms of life could emerge. Milan Ćirković, posing this question of 'astrobiology', insists that we ought not to let the confined shores of our island existence mislead us into thinking that this is the only 'habitable zone' in the sea of possibilities. Instead, he hypothesises, there may be an 'archipelago of habitability', a system of islands whose pattern might even be mathematically discoverable. Artist Charles Avery's 'Sketch for an Archipelago', with its spiral structure, illustrates the hypothesis perfectly.[2]

---

[1] Text of a public lecture given in January 2009 at the Scottish National Gallery of Modern Art to accompany Charles Avery's exhibition *The Islanders: An Introduction.*

This notion of the tiny habitable island in a vast sea of possible universes belongs to a novel philosophical discourse subtended by contemporary physical and mathematical concepts. But it attests to the fact that certain enduring images continue to constitute something like pieces of a re-usable theatrical stage-set for philosophical thinking. The image of the island is one of these, and is as old as Western philosophy itself. Charles Avery, like many before him, has taken up this concept of the 'philosophical island' and made it his own. In order to understand Avery's contribution to this history, we shall take a historical tour – inevitably very selective – through the various ages of the philosophical island. This subject, and its history, are so rich in particular because philosophy shares the 'geophilosophical concept' of the island with literature. In fact, the island has always defined an important relationship between the two: The island is a kind of conceptual laboratory for transplanting stories into ideas, for imbuing narratives with concepts, for bringing ideas alive through myths.

---

[2] See Milan Ćirković, 'Sailing the Archipelago', **Collapse** V, 292-329.

The island first appears when Western philosophy, at its birth, is still negotiating its divorce from its other: namely, myth. In Plato's *Timaeus* the fable of the island of Atlantis occurs within a discussion of the rational principles of a perfect society. Socrates complains that, whilst he *understands* the conclusions arrived at, he would 'compare [him]self to a person who, on beholding beautiful animals either created by the painter's art, or, better still, alive but at rest, is seized with a desire of seeing them in motion or engaged in some struggle or conflict to which their forms are suited'.[3]

This demand of Socrates sets in motion the history of the philosophers' island. The demand for something to *bring alive* ideas; to quicken the still body of rational discussion, finds satisfaction in the story of Atlantis, the lost island.

As we know, Plato's dialogues often comprise secondhand reports, but the *Timaeus* ramifies further this strategy of framing, as the story of Atlantis is reported by Socrates' friends as an ancient story heard from a grandfather, who in turn heard it from a friend of *his* great-grandfather, Solon, who received it from an Egyptian priest. Through this relay of memory, Plato establishes Atlantis at an immemorial distance from his audience, endowing it with a properly mythical status.

The priest's story is of a war waged by the island kingdom of Atlantis against the city of Athens – but this is an Athens separated from Plato's contemporary Athens by an impassable gulf of forgetting. For the flooding of the nile, as the priest tells Solon, has on many occasions saved the Egyptians, and their knowledge, from great catastrophes periodically visited on the Earth and which have wiped out many other peoples including the Greeks. In this way Plato gives his audience to understand that they belong to a shallow memory cut off from the deep past in which the story takes place. Hence the priest's gnomic declaration: "You Hellenes will never be anything but children".

---

[3] *Timaeus* 19b.

At the climax of the war both (the immemorial) Athens and Atlantis were inundated by a great flood, and their people, Plato tells us, 'disappeared in the depths of the sea'. The island of Atlantis never reappeared, but Athens rose again from the waters. Reborn into an immature state, stripped of its former glory, the 'infant' Athens would have to learn once again to be the perfect republic.

This unveils the original function of the philosophers' island as being connected with a mythical conception of time, with forgetting and memory, with re-beginning and with founding; It sets up a theme of utter oblivion and forgetting only so as to pose the question of the new foundation – no island, therefore, without the flood.

How does this myth transform the philosophical discussion of Socrates and his friends? 'The city and citizens, which you yesterday described to us in fiction, we [...] now transfer to the world of reality'. Paradoxically, fiction imparts reality to the philosophical discussion. For the ideal city they had discussed now becomes the city of their *own* lost ancestors. Where there was the mere *idea* of a city run on rational grounds, now there is the prospect of a repetition, the fulfilment of a cycle. The island myth, of course, dramatises the notion of *anamnesis*, or *un-forgetting*: Rational insight comes not from our experience of this world, but from a remembering of an *other* world, the recovery of a pure knowledge that was lost when we were incarnated.

Plato's Atlantean myth rises again as the perfect narrative form for the ideals of the humanist Renaissance – naturally, considering that it precisely concerns a 'rebirth'. In Francis Bacon's 1623 *New Atlantis*, for example, all the important elements are reworked: A crew lost in a 'part of the South Sea […] utterly unknown', cut adrift 'in the midst of the greatest wilderness of waters in the world', discover the island of Bensalem, whose perfectly-calibrated civilisation, with its gentle, humanistic, scientifically-advanced government, embodies all of Bacon's aspirations for the improvement of human society. The people of Bensalem, it transpires, whilst their existence is perfectly unknown to the rest of the world, have an astonishingly complete knowledge of the whole globe, and their civilisation has endured from time immemorial, from before the 'universal flood'. Of the people of this island, too, one could well say: 'you Europeans will never be anything but children'. Again, Bacon's advanced ideas on society and science, in the mouths of these fictional, antediluvian islanders, become an invitation to repeat: Not only does his 'New Atlantis' repeat Plato's, it also calls his contemporaries to repeat the example of the people of Bensalem.

But we are getting ahead of ourselves: For we should remember the extent to which, before the Renaissance, It was Arabic philosophers and commentators who nurtured and developed philosophical thought. And the concept of the philosophical island is no exception. One remarkable text by a Spanish muslim philosopher could, without much exaggeration, be described as being halfway between

Aristotle and *Robinson Crusoe*. This is Ibn Tufayl's book 'Hayy ibn Yaqzân', a twelfth-century arabic text translated into English in 1708 as 'The Improvement of Human Reason', known in Latin as '*Philosophus Autodidactus*' ('the self-taught philosopher'). This is a text known to have been influential for some of our most enduring modern myths: *The Jungle Book*, *Robinson Crusoe*, *Tarzan* to name but a few. Tufayl's narrative tells the story of a child named Hayy ibn Yaqzân, who is cast away on an unpopulated island, and raised by gazelles. The narrative follows the development of this castaway's philosophical meditations as he grows up and discovers the world, in isolation from all human contact.

Tufayl's book is essentially a philosophical treatise, speaking of all things from biology to planetary motions. But its form is that of a progressive narrative, recounting how these philosophical reflections emerge in a man reduced to his 'natural state', removed from all cultural influence: We see Yaqzân growing up among animals, first lamenting his own weakness and vulnerability relative to them, then discovering the uses of his hands, making clothes, devising tools and weapons. He discovers fire and cooked food, thus awakening his human difference from the animals. But his philosophical development really begins in earnest when his gazelle-foster-mother dies. This precipitates a reflection upon what is alive in an animal being, with Yaqzân concluding that the body is 'a very inconsiderable thing', and beginning to foster a conception of the soul. Thence to the questions of how the soul is conjoined with the body, with the conclusion that the soul is akin to fire, a kind of warm vapour. The individuality of each being must then consist in this 'vapour'; and Yaqzân conceives an analogy between his own use of various tools, and this vapourous spirit's use of the various animal bodies for different purposes. With lengthy meditations on unity and plurality, individuals and species, the self-taught philosopher rediscovers the principles of Aristotelian taxonomy, and proceeds to classify the entire animal and vegetable kingdom, finally considering inanimate objects, and coming to the conclusion that 'all these things [are] in reality one, though multiplied and diversified accidentally as the plants and animals [are]'. But what then is the nature of this unified substance that underlies all these various things in the world? ... With further meditations reaching ever more abstract questions and lofty conclusions, the feral child Yaqzân achieves philosophical enlightenment as an adult.

In fact Yaqzan does make contact with civilisation again, through the medium of a holy man who comes to the island to meditate; however, after having returned to his fellow humans, he finds them so unwilling to consider the way of wisdom that he returns to his island.

This remarkable story is the first fully *philosophical* use of the island. Recounting the genesis of philosophical thought as a natural development, it serves to ratify a body of doctrine as belonging to the natural progression of reason, untainted by outside influences. And the function of philosophical islands continues to be involved with this desire for purity – with philosophy's impatience with dogmatism or received wisdom, its compulsion to begin from nothing, to re-begin with no presuppositions, to *found* itself. For the philosopher, the island is a chance to begin over again, giving us the possibility of re-founding our knowledge on the basis of an imaginary innocence.

Returning to the Renaissance and to its utopias – those New Atlantises reflecting the optimistic spirit of the age – the most important is probably Thomas More's 1516 fictional crescent-shaped Atlantic Island *Utopia*, a name which of course harbours an etymological ambiguity: 'no-place' and 'good-place'. It's precisely an ideal which cannot be fully realised but which might serve as an orientation, a navigation point: More's discussion of the ills of society, the vanity of people, the belligerence of leaders, gives us an enduring model of sociological and philosophical reflection that is very much alive two hundred years later – in more satirical form – in *Gulliver's Travels*, which however teaches through a mocking *reductio ad absurdum*, not by example, and is all the more entertaining for it.

Where Ibn Tufayl's account of the gazelle-child Hayy ibn Yaqzân contained both an treatise of philosophy and a philosophical thesis on the genesis of thought in one isolated individual, these political fables use the island as a controlled setting for thought-experiments concerning the foundations of the social. A great seminal moment in philosophical island literature occurs, however, when these two aspects – the innocent *individual* finding enlightenment in the seclusion of an island, and the ideal island *society* prompting reflection on our own – are brought together. This is Defoe's 1719 *Robinson Crusoe*.

In *Robinson Crusoe* all the essential problems of the philosophical island are brought together beautifully. We have Crusoe as Christian autodidact, discovering true faith through his own solitary meditations. But it is not only

God that Crusoe discovers: he also enacts the origins of sedentary human society: The need to settle and defend, the planting of crops and building up of stores, the need to domesticate wild animals, even the development of hierarchy and the legitimacy of servitude … But *Crusoe* is also the point at which the philosophical island comes into disrepute, when we begin to harbour suspicions about the supposed innocence of the protagonist. Readers excited by the idea of the shipwrecked mariner exploring the virgin isle, surviving on his wits, cannot but be somewhat disappointed when Crusoe spends his first two weeks rowing back and forth to the shipwreck to bring out everything he needs to set up home, from gunpowder to tunics, from oatcakes to a complete set of carpentry tools; cannot help feeling a little cheated when he takes his smug walks to his 'country house' with his four guns slung around him, or when by 'chance' he discovers some ears of wheat and prudently sews and stores his harvests for three years …

At a century's distance Marx sums it up drily in the first volume of *Das Kapital*: 'having saved a watch, ledger, ink and pen from the shipwreck, he soon begins, like a good Englishman, to keep a set of books'.[4] For Marx, Crusoe represented 'a totally illusory foundation for economics, that of the independent, non-social being'. The story was an ideological sham, serving to naturalise the system of bourgeois capitalism, its function to justify a system through a bogus mythical 'proof' of its spontaneous nature. In short, the island is 'a false "origin"'.

In his 1946 essay 'Causes and Reasons of Desert Islands', Gilles Deleuze, whilst affirming the philosophical power of the island myth, seconds Marx's suspicions. The problem with *Robinson Crusoe*, he writes, is that Defoe's narrative fails the profound sense of the *reinvention* of mythology that characterises the philosophical island: In *Crusoe* 'The mythical recreation of the world from the deserted island', Deleuze says, 'gives way to the reconstitution of everyday bourgeois life from a reserve of capital. […] Robinson's vision of the world resides exclusively in property. Nothing is invented.' He continues, somewhat harshly: 'One can hardly imagine a more boring novel, and it is sad to see children still reading it today […] Any healthy reader would dream of seeing [Friday] eat Robinson.'[5]

---

[4] K Marx, *Capital*, vol I, tr. B. Fowkes (London: Penguin, 1992), 170.

Despite these cavils, the structure of Robinson Crusoe so perfectly distils the island concept that it has proved robust enough to be critically rewritten, not only in countless inferior and derivative novels, but also in many inventive and subversive ways: For example in the wonderfully philosophically-rich 1972 novel *Friday, or the Limbo of the Pacific* by Deleuze's friend Michel Tournier. Tournier's Robinson, on the island he names 'Speranza', is depicted in the light of a philosophical and psychoanalytical mélange combining Freud, Jung, existentialism and structuralism. For Tournier, the story becomes that of Robinson discovering that what made him human was his interaction with others. Alone on the island, he begins to succumb to depersonalisation, sinking into a delirium where he identifies himself increasingly with the island. The very delirium against which Defoe's Crusoe had defended himself implacably with all the salvaged accoutrements of civilisation becomes, for Tournier, the truth of the island adventure as philosophical, psychotropic journey. As he struggles to 'humanise' the island, Robinson becomes dehumanised, becomes the island: 'So Robinson is Speranza. He only has a consciousness of himself by way of the fronds of myrtle, through which the sun launches its arrows of light, he only knows himself in the foam of the wave washing across the white sand'.

---

[5] G. Deleuze, *Desert Islands and other Texts*, tr. M. Taormina (Cambridge, Mass.: MIT Press, 2003), 12.

The influence of Tournier's novel can be read in J.G. Ballard's short 1973 novel *Concrete Island*, in which – with typical mordant wit – a businessman finds himself car-wrecked on a traffic island. Unable to escape, this hapless protagonist also undergoes a kind of psychogeographical trial, repeating, at the height of his ordeal, the phrase of Tournier's Robinson: 'I am the island'.

Between Crusoe's island and the Concrete Island, we must also note a great efflorescence of what can only be called island narratives without islands: The social contract theorists. The thought-experiments of Hobbes, Locke and Rousseau, imagining how society might develop from a 'state of nature', are the great speculative works of modern political philosophy. These theorists rightly saw that the island-principle corresponded to an important truth: The real – even the reality of society – can be profoundly explored only through an ideal scenario, a controlled experiment, that steps beyond the bounds of that reality. In the twentieth century, John Rawls re-imagines the social contract experiment using imagery that corresponds to that of isolated islands such as Bensalem, with the 'veil of ignorance' an impenetrable bank of fog around the philosophical island. To make his argument, however, Rawls for the first time posits the 'original position' of the philosopher *outside* the island, meditating on the possibilities of what it might hold and planning his disembarcation.

Even if social contract theory represented in certain respects the consummation of the political employment of the philosophical island, in a new modern conception of the 'grounding' or re-foundation of the social on the model of a civil contract, from the nineteenth century onward its works were liable to come under suspicion, and to be dismissed as 'robinsonades': post-*Robinson Crusoe* any supposedly 'innocent' deployment of the island as a speculative device would be subject to great critical scrutiny.

In marking out Reason's legitimate from its illegitimate uses, Kant's *Critique of Pure Reason* aims to provide the map for a domain of well-founded, systematic knowledge, and secure it against the flights of fancy and the speculative excesses to which Kant considered earlier philosophers had all-too-easily abandoned themselves. And yet to promote this somewhat gruelling task Kant employs the image of the *island of truth*, in this famous passage from the *Critique of Pure Reason*:

> We have now not merely explored the territory of pure understanding, and carefully surveyed every part of it, but have also measured its extent, and assigned to everything its rightful place. This domain is an island, enclosed by nature itself within unalterable limits. It is the land of truth – seductive name! – surrounded by a wide and stormy ocean, the native home of illusion, where many a fog bank and many a swiftly melting iceberg give the deceptive appearance of farther shores, deluding the adventurous seafarer ever anew with empty hopes, and engaging him in enterprises which he can never abandon and yet is unable to carry to completion. Before

> we venture on this sea, to explore it in all directions [...] it will be as well to begin by casting a glance on the map of the island which we are about to leave, and to enquire, first, whether we cannot in any case be satisfied with what it contains – are not, indeed, under compulsion to be satisfied, inasmuch as there may be no other territory upon which we can settle; and, secondly, by what title we possess even this domain, and can consider ourselves as secured against all opposing claims.

As Michèle le Doeuff remarks in her *The Philosophical Imaginary*, Kant uses the image of the island to defend his sober 'critical philosophy' against the more colourful and grandiose promises of speculative metaphysics: The 'critical' island is certainly not a paradise – but it is infinitely preferable to the frustrations and dangers of the boundless ocean, upon which metaphysical speculation recklessly sets out. If he claims to re-place our knowledge on its proper ground, Kant is most circumspect about what sort of territory philosophy can promise to secure for us.

Notably, as le Doeuff remarks, elsewhere Kant warns against *another* island: the paradisiac island of the South Seas. The yearning for its easier climes and for its innocence is a snare, Kant suggests: they represent a pernicious, imaginary utopia. Thus Kant sets the seduction of the southern isle against the foggy northern isle which, whilst somewhat bleak, is true and solid. As Deleuze says in his book on Kant, this is the element in which Kant's thought is at home: 'the fog of the North'. When Kant trills 'the island of truth – seductive name!', this is nothing but sarcasm: the *serious* philosopher has no business with seductive, pretty islands where he can lounge about all day under palm trees.

So Kant reinvents the philosophical island as a duality: There is the southern isle, with its dangerously desirable holiday-brochure illusion of luxury and leisure; and the northern isle, safe, secured, and systematic, if a bit grey. In short, the island of truth is a *dreich* isle, but it's all we've got. But even Kant's carefully-delimited and hard-won piece of solid territory doesn't last long in the history of the philosopher's island, as Nietzsche, in his 1882 *The Gay Science*, announces the crisis of late modernity – not only have we left Kant's island of stability, our own critical self-consciousness has destroyed it:

> In the horizon of the infinite.– We have left the land and have embarked! We have burned our bridges behind us–indeed, we have gone further and destroyed the land behind us! Now, little ship, look out! Beside you is the ocean: to be sure, it does not always roar, and at times it lies spread out like silk and gold and reveries of graciousness. But hours will come when you will realize that it is infinite and that there is nothing more awesome than infinity. Oh, the poor bird that felt free and now strikes the walls of this cage! Woe, when you feel homesick for the land as if it had offered more freedom–and there is no longer any 'land'!

In the epoch that this declaration announces, the problem is no longer that of founding or re-founding. Instead it is the crisis of the fruits of enlightenment turning bad, of science and critical thought having gnawed away the very foundations of human existence. But even Nietzsche's declaration that there is 'no longer any "land"' cannot prevent literature from re-engineering the island for this age, and according to its dreams and fears. From the end of the nineteenth century, the philosophical island becomes a dystopia where the most extreme possibilities, doubts, and horrors of Western civilisation are given free (if safely-sequestered) rein. This tradition begins with H.G. Wells' (1871) *Island of Dr Moreau.* Rather than the island being a metaphorical setting for a *philosophical* thought-experiment, instead we find ourselves on an island where actual (scientific) experiments are underway and running out of control. The island becomes a warning, concentrating the most threatening aspects of contemporary reality into their confined space.

Instead of accommodating an ideal society whose principles instruct our own, then, the twentieth-century island – in which we can include, of course, many of science-fiction's alien planets and stranded space-stations – is more likely to amplify developments of real society, concentrating them into an imagined future that is all-too-near. The power of ideas, rather than being owned and judiciously employed by philosophy, is now a power effectively at work in the world, embodied in technology, uncontrolled or controlled by megalomaniacs and evil geniuses, perplexing and injuring humanity. This, in short, is the philosopher's island resounding with the aftershock of World Wars; and the island *after* Marx *after* Freud, *after* Darwin.[6] And after the twentieth-century revolution in physics: it is the Island of the fateful experiment – the Bikini Atoll – and its aftermath (*Lord of the Flies*, and countless other post-apocalyptic fantasies).

---

[6] Incidentally, we should remark that we owe the whole elaboration of evolutionary theory from Darwin onward, to an island voyage – Darwin's journey, onboard the *Beagle,* to the Galapagos, islands whose slow geological drift apart had effectively isolated the different species of finches, which thus provided a living stop-motion image of the process of natural selection. Note, however, that in his new book biologist Steve Jones argues that despite their mythical importance in the popular imagination, in actual fact the most important island for Darwin's work was England. S. Jones, *Darwin's Island: The Galapagos in the Garden of England* (London: Little, Brown, 2009).

In his last novel, entitled imply *Island* (1962), Aldous Huxley seems to reverse the trend: He turns the island once more into a utopia contrasting with the dystopia of reality. Imagining science being harnessed only for the use of man, rather than overpowering him, Huxley's 'Pala' is an imaginary island of sanity in a mad world, where Eastern wisdom and Western science comet together in the persons of a shipwrecked scientist and an indigeneous quasi-buddhist order, giving birth to a society stable and free from madness and venality. Like the autodidact Yaqzân, everyone on the island is in a state of enlightenment, nirvana even. And through the great slogan of this modern Utopia still echoes the voice of Platonic *anamnesis*: 'Nobody needs to go anywhere else. We are all, if we only knew it, already there'. If only we knew it, we could repeat, return to where we really are. Ultimately, however, the final twist in Huxley's tale shows that he was himself no longer convinced of the possibility of such a 'sane society', such a return to the source.[7]

Let's now ask whether we can make out the shape of a new, twenty-first century philosophical island? Previous models still haunt us: Just as, in the sixties, *Lost in Space* reworked *The Swiss Family Robinson* for the space age, Koushun Takami's (1999) comic book *Battle Royale* and its (2001, 2003) film adaptations unfolded as an ultraviolent revisiting of *Lord of the Flies*; and the TV series *Lost* (2004-5), with its plane-crash and its characters named Locke and

---

[7] In a typically cynical reappropriation of Huxley's combination of science and religion, Michel Houellebecq's (2005) *The Possibility of an Island* returns it to reality. Houellebecq envisions an island run by a 'cloning cult', based on the actual cult 'Raelians' - a real world example of the terrifying combination of genetic engineering, nanotechnology and religious messianism.

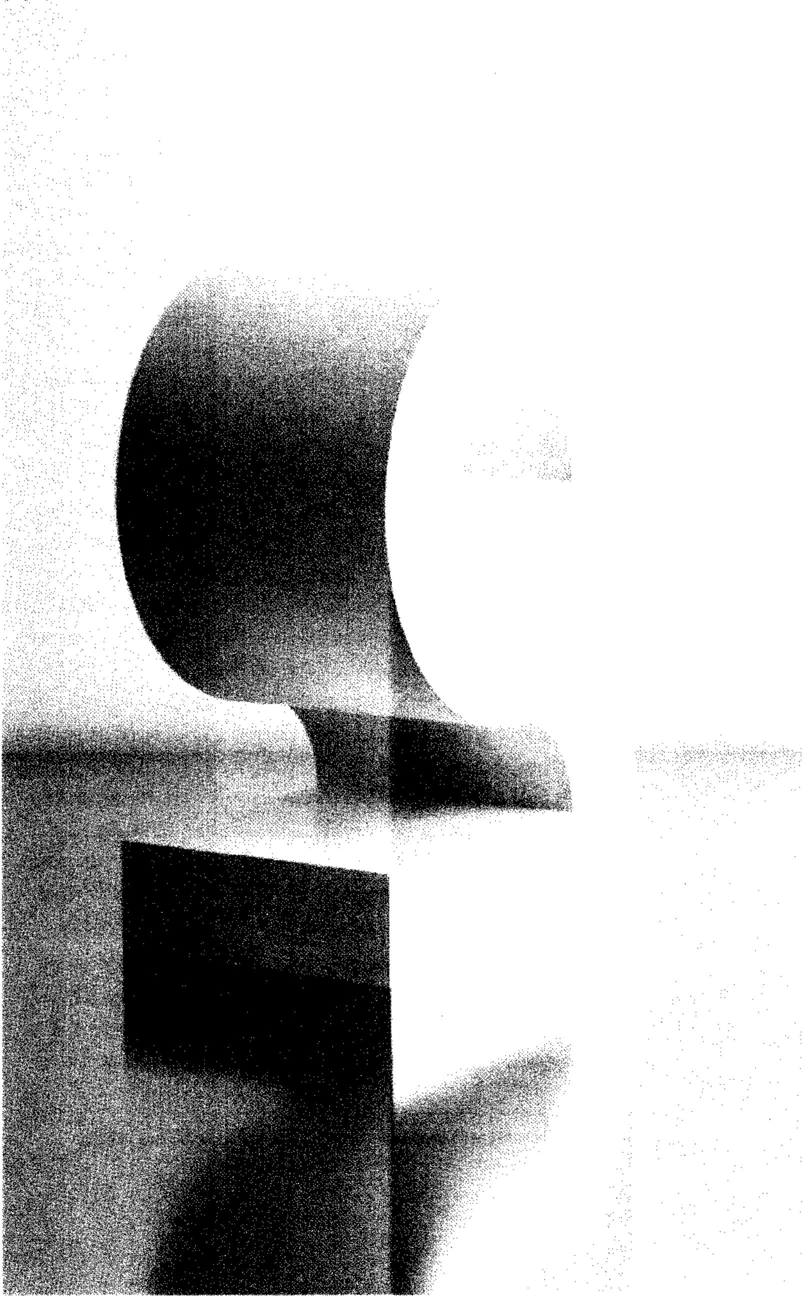
Rousseau, remixes a bygone era of island thinking. At the end of the second episode of *Lost*, entitled 'Tabula Rasa', one of the characters declares: "This is a chance for everyone to start again, regardless of what they were before the crash". Utopia endures in Hollywood, even if the tale of *Lost* becomes darker and more twisted (fatiguingly so) as the episodes progress.

Perhaps ours is more properly the age of the house-island, isolated but visible by millions, and manipulated by an unseen controller. *Big Brother* and its various reality TV imitators (several of which take up the island theme very literally, with woeful results), although they harbour no illusions of a *tabula rasa* or a complete new beginning, are perhaps still rather tied to antiquated forms, their social engineering redolent of *The Tempest*, where the audience delights in Prospero's behind-the-scenes manipulation of the hapless groups shipwrecked on his enchanted isle. Ours is also the age of the geoplastic megalomania of Dubai's man-made archipelagos, where millions of tonnes of sand is dredged up from the bottom of the sea to create new islands full of luxury villas. (Have their architects never heard the phrase 'built on sand' ...?) Since every modern convenience has already been imported, however, the rich man's island is never interesting, it's never a desert island. None of these constitute a philosophers' island for today.

The philosophical references of Charles Avery's work set the conditions for one possibility of what such an island might be. And his project itself responds to them. It's a project which resides as much in his book,[8] at once an

---

[8] C. Avery, *The Islanders: An Introduction* (London: Parasol Unit/Koenig, 2008).



island travelogue and an enigmatic work of philosophy, as in the catalogue of drawings and exquisitely-crafted objects in different media which make up his oeuvre.

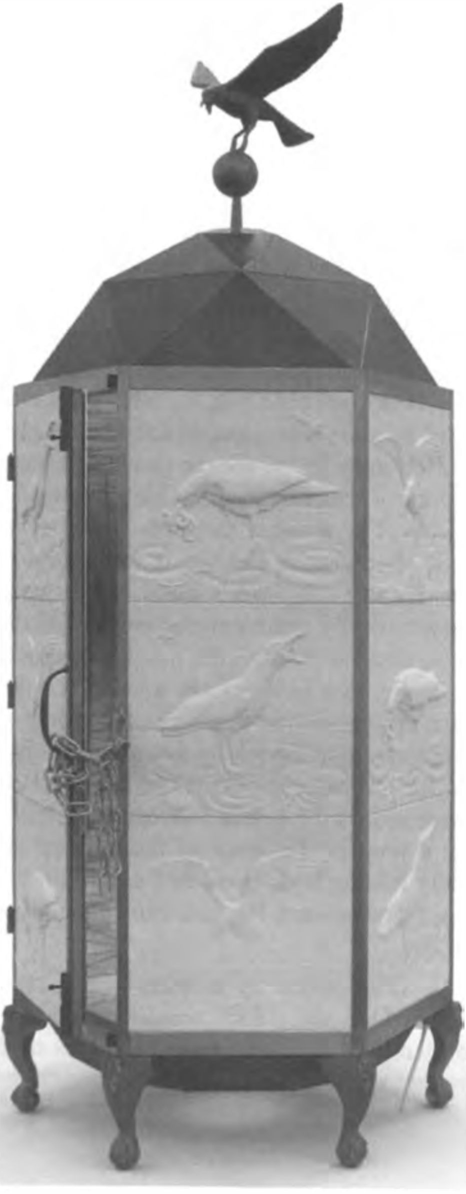
At first, Avery's island seems to represent the landscape *of* philosophy, rather than being a vehicle for any particular philosophical thesis. Looking at the names on his maps, it seems Avery wishes to make the landscape of his island and the world surrounding it describe the whole history of philosophy. In this, his closest reference is Borges' (1940) story *Tlön, Uqbar, Orbis Tertius*, which tells of a researcher's discovery of a land – possibly real, possibly conspiratorially fabricated by scholars – whose regions can be differentiated according to their inhabitants' subscription to different philosophical theories of meaning. But if we read Avery's island as some sort of grand allegory, we soon find out that there is no straightforward 'mapping'. Far from simplifying the world of ideas by mapping it out, Avery adds to it and twists it with his strange cartographies. The relation between metaphor and what is metaphorised is always slipping and sliding, and everything refuses to fit together neatly.

There are however some privileged philosophical references. They belong to the development of the philosophy of logic and mathematics at the beginning of the twentieth century, the story of the search for a theory that would provide a systematic foundation for all logical and mathematical thought. One of the few actual philosophers to appear in Avery's drawings, Bertrand Russell, has the great distinction of having ruined this idea forever, in his polite letter to his colleague Gottlob Frege. The simple but powerful paradox discovered by Russell, and which bears his name, resonates throughout Avery's work: Take the set of all sets which are not members of themselves: if it does belong to itself, then it doesn't – And vice versa … Take the barber of the regiment, defined as the man who shaves everyone who doesn't shave themselves … does he shave himself or not?? (You'll find Avery's own answer to that particular riddle in his book.) Russell's paradox seems to be the engine of all the dualities in Avery's work. His islanders love to cut everything in the universe in two. In fact, the apotheosis of the islanders' creed might be the old joke that 'there are only two types of people; those who divide people into two types and those who don't'. But the island is also prowled by anomalous animals that don't seem to obey these distinctions: The Elusive Noumenon; The If'en, whose 'defining characteristic […] is that they lack a defining characteristic';[9] The Essential Mr Impossible … one suspects these are the animating principles of the island, paradoxes that not only accompany the sharp distinctions the islanders like to make, but might even sustain them, as the hope of snaring the Noumenon sustains the hunter.

The disorienting effect of all these paradoxes is already a little like stepping into Avery's 'Eternity Chamber'. But there is more. Russell had shown that the most powerful foundational logical theory was punctured by paradoxes. But by the 1930s, Gödel had proved his incompleteness theorem, demonstrating that any logical system powerful enough to provide a foundation for simple arithmetic *will* contain at least one proposition whose truth is undecidable. This shatters philosophers' dreams. Avery's work registers both the gravity and the humour of these developments.

---

[9] Avery, *The Islanders*, 47.



No foundations: does this mean no islands? 'In the horizon of the infinite', neither philosophy nor art can rise above or systematise the All, or provide it with a foundation. philosophy and art are themselves situations within the world, and all situations are incomplete. Avery's work constantly presents us with this 'punctured' and incomplete state of knowledge.

In this respect, one might relate Avery's work to that of an apparently very different artist, Keith Tyson. In fact Tyson shares similar formal concerns, since his work wrestles with the idea of systems that strive to encompass and tabulate. In *Large Field Array* Tyson tries to create a modular 'system of everything' – scientific theories, his childhood memories, images from TV, abstract concepts – and systematically connect it all together. But he is inevitably faced with having to rescind this work's claim to be comprehensive or to systematically represent the world. Of this 'failure' Tyson says that we must accept that it's impossible for the artist to create, in a work of art, a model of the universe that doesn't participate in that universe; works are models *in* the universe, not models *of* the universe. In an image very apt for the present discussion, he says that they are 'like a postcard on the beach'.[10] Avery's work is something like this: a map of the space of thought we inhabit, but continually folding back upon that space, so that the map can never be completed, but continually complexifies what it's mapping.

G. K. Chesterton, in a witty piece entitled 'The Philosophy of Islands' (1903), remarks on the very human need to identify things, and sees at the root of this a wish to isolate. It is to this desire that he links both what he calls the 'perennial poetry of islands' and 'the perennial poetry of ships':

---

[10] Keith Tyson, *Studio Wall Drawings 1997-2007* (London: Haunch of Venison, 2007), 27.

> A ship like the Argo or the Fram is valued by the mind because it is an island, because, that is, it carries with it, floating loose on the desolate elements, the resources, and rules and trades, and treasuries of a nation, because it has ranks and shops and streets, and the whole clinging like a few limpets to a lost spar. An island like Ithaca or England is valued by the mind because it is ship, because it can find itself alone and self-dependent in a waste of water, because its orchards and forests can be numbered like bales of merchandise, because its corn can be counted like gold, because the starriest and dreamiest snows upon its most forsaken peaks are silver flags flown from familiar masts, because its dimmest and most inhuman mines of coal or lead below the roots of things are definite chattels stored awkwardly in the lowest locker of the hold.

This explains why earlier philosophers' islands now appear to us to be typical 'philosophers examples' – they are commodious to the mind only because of their oversimplicity. The contemporary island can no longer pander to the desire for isolation, because we know our world is complex, interconnected, and uprooted: There *are* no more desert islands. Nicholas Bourriaud calls Avery's island a 'heterotopia' rather than a 'utopia': it's neither 'no-place' nor 'the best place', but an 'otherplace', a 'manyplace', a multiplicity that is already 'out there'. It is the multiverse as refracted in Avery's mind. His question, though, is how to create 'one' out of this dazzling multiplicity. This is precisely the task Avery set himself when, in the inaugural gesture of his mammoth project, he declared that from now on *all* of his work would find a place in this island kingdom (so that the 'work' consists not in any one of the objects created, but in the structural consistency of the whole).

In regard of the need to isolate things, Chesterton speaks also of the fear of infinity: for 'to be infinite is to be shapeless', he says. However, as Alain Badiou has argued, it is the *finite* that is the exception: infinity is normal. Every thing, every situation, can be seen from infinitely many perspectives, dissected in infinitely many ways; so that things are never one in themselves, they are always multiple, infinitely multiple: To 'count-as-one' a situation or a thing is always to intervene in it, to creatively shape it.

Cantor's transfinite mathematics, which Badiou suggests we take as one of the conditions for contemporary philosophy, is the third of Avery's philosophical sources to which we should draw attention: Cantor's proof that there are different *sizes* of infinity, which secularises the concept of infinity and introduces some exquisite paradoxes into thought. For on Avery's island we meet the strange, ramified quasi-elephantine creatures the Alephs, believed by some to be 'descendent[s] of the Noumenon', of which we are told: 'upon the discovery that Aleph Null was not unique, the ideas accounting for the species were modified'.[11]

And infinite variety is certainly reflected in Avery's island – it may be a 'northern isle', but it is not ordered and bleak like Kant's 'island of truth'. It's an island of gods and pickled eggs, of bagatelle and pyramids, of seagulls and alephs. All these things, belonging to very different registers of reality, co-exist on the island, depicted through Avery's work through a constantly-evolving palette of techniques and media. Thus the aforementioned structural principle of Avery's project is a way for the artist to 'count himself as one', to bring together all the different situations of which he is an intersection: philosophical ideas, places, concepts, people he's seen or known, historical figures, imaginary situations from books – without suppressing their multiplicity. The idea of the 'whole project' always goes before him as a task that will never be finally completed. There is always more for him to discover on this island, now that he's decided that the island is where everything will be.

---

[11] Avery, *The Islanders*, 50.

He therefore suggests a contemporary role for the philosophical island, for individual and society alike: stifled by a wealth of multiple possibilities, we lack any immemorial, mythical example to repeat; there is no deep past, no 'before the flood', that unifies us; We can't appeal to memory anymore for political strength, to tradition for identity, or to ideal models for simplicity. It is therefore no longer a question of *founding* ourselves on the basis of mythical islands. Rather, given this multifarious reality, the problem is to find *ourselves in* it - or to *hunt* ourselves in it, in the process adding to the territory with yet more maps.

Finally, Avery's story is also about the practice of philosophy itself. His protagonist comes to the island with a view to being its discoverer - he craves the glory of discovering something new.[12] But he immediately finds he's not alone. The fantasy of the Victorian explorer is already dispelled on page one of Avery's travelogue. This in itself is the condition of doing philosophy in the present day: a sometimes disheartening process of discovering who has already had your thoughts before you. You're exploring a land that seems, to you, to come directly from the deepest part of yourself and to contain the strangest, most intangible thoughts; But you constantly have to accept others have been there before you, already mapped, charted, and named these zones of thought, just like the names on Avery's map: *Descartes' axiom*, *The phenomenon of sense*; *The procession of the Greeks* (an archipelago which includes the island of Timaeus). To think today, is to negotiate an historical constellation of thought-positions; *anamnesis* become historical. It is the problem, not of how to begin from nothing, but of how to synthesise existing, multiple lines of thought into something new. This quandary, this weight of history, was the same in which Avery found himself with respect to an overly historically-conscious discourse of art. The island, the construction of this island that belongs only to Charles Avery, more than the sum of its parts, more than any one narrative, is his response.

---

[12] Avery, *The Islanders*, 9.

According to Avery, if one can't be a discoverer, the only thing to do is to reinvent oneself as a hunter, trying to locate the island's greatest treasures, those that have eluded everyone so far. If Avery says that this characterises the figure of the artist, one would be inclined to say it corresponds also to the figure of the philosopher: 'an eternally hopeful and eternally hopeless individual. Even though history and reason tell him otherwise he continues to believe he will prevail'.[13] As we have seen, the history of philosophers' islands is a moving image of this eternal hope.

The Islanders: Epilogue[1]

Charles Avery

This is the plain where Rocco once found a dead monster.

Within its thinness I am profoundly lost.

Multitudes of round white flowers vanish into the endless ring of light on the horizon, and there is little else, other than the wind, which ruffles the meadows.

Every so often I think I see, at the edge of my vision, some small animal flitting, but I cannot say that any of these sightings are conclusive.

I resolve to fix my eyes downwards and comb the ground in search of any sign of diversity.

A little flat stone … the remains of a small and long-dead creature … possibly … strange S-shaped lines in the dust… some foamy substance on a stalk … another stone ... an old bottle!

When turned upside down and shaken, it yields a few drops of rusty red liquid which disappear into the ground.

---

[1] Text originally commissioned by *To Hell with Journals* and published as 'The Fancy of the Hunter', in issue d (Nov. 2009), eds.. C. Arsène-Henry and H. U. Obrist.

Many have ventured to the remotest part of this far off isle. Some return to tell the story. Those who do say they came in search of something new, for it is the fancy of the hunter that, in this reified atmosphere, a beast called the Noumenon may reside. The existence of this creature has never been proven, yet there is a deep conviction that it must indeed be, and do so here, in the wilderness, for the rest of the Island is well charted.

Some come alone so as not to alarm the creature, but hope to enchant it – yet any sighting reported by such solitaries is dismissed as the altitude induced hallucination of the wishful, or the fabrication of the charlatan. Others come in pairs so as to have somebody to corroborate their testimonies, but none have been successful. It seems ‘Three’s a crowd’ as far as the Noumenon is concerned.

Then there have been great enterprises where hundreds have come up here, with dogs and nets, and all manner of contraptions, and have sought to encircle the creature, fruitlessly.

This is clearly a being of infinite finesse. Its existence is sustained by faith alone, or, as The Urbane Wit commented: “It’s behind you!”

Nevertheless there is an ocean of amnesia that new generations must cross to come to the island; and as they pull their barques ashore and savour the moist air, each expedition with its newest equipment, a picture of jovial young women and men on the beach, full of optimism as they head for the darkness.

I too was drawn up here by the scent of this enigmatic cat, and am all regret. I would gladly settle for the impression of its droppings if I could be delivered from this situation.

I am disgusted with my weakness of character, for I must admit that a sickening loneliness has come upon me more quickly and profoundly than I imagined it could. I yearn to be planted back in the marginally less lonely situation of the café in the outpost of Onomatopy, where I first conceived this misguided expedition. Where a rude waiter dumped my coffee in front of me, spilling a good deal in the saucer, conducted exclusive banter with the barmen and made lewd comments about inaccessible females (to him through coarseness, to me through shyness) who walked past the window. Where two huge men in tall hats sat strikingly by a mirror on the wall, engrossed in conversation. A mendicant wandered into the café and mumbled something to me in dialect, about milk for his baby (absent) – from which I understood that he wished to indent me for currency – and stood around for several seconds after my refusal, allowing me to inhale his hum. I thought, drat, why don't the waiters intervene and remove this loon from the premises. To my discomfort he then took a place at the bar, where he appeared to be on first name terms with the staff, and proceeded to imbibe a coffee, served to him immaculately, apparently on the house, exchanging friendly salutations with the giants in the corner as he did so.

But I am far from Onomatopy, and I do not know my way back, indeed death is closer than town.

Yesterday I saw that pretentious hare, at a distance. It stopped a moment and looked in my direction, I thought in pity. I hoped it might point the direction home, but instead it just flashed its rings at me, and passed on. As an afterthought I fumbled a couple of cartridges into my gun but the hare was long-gone.

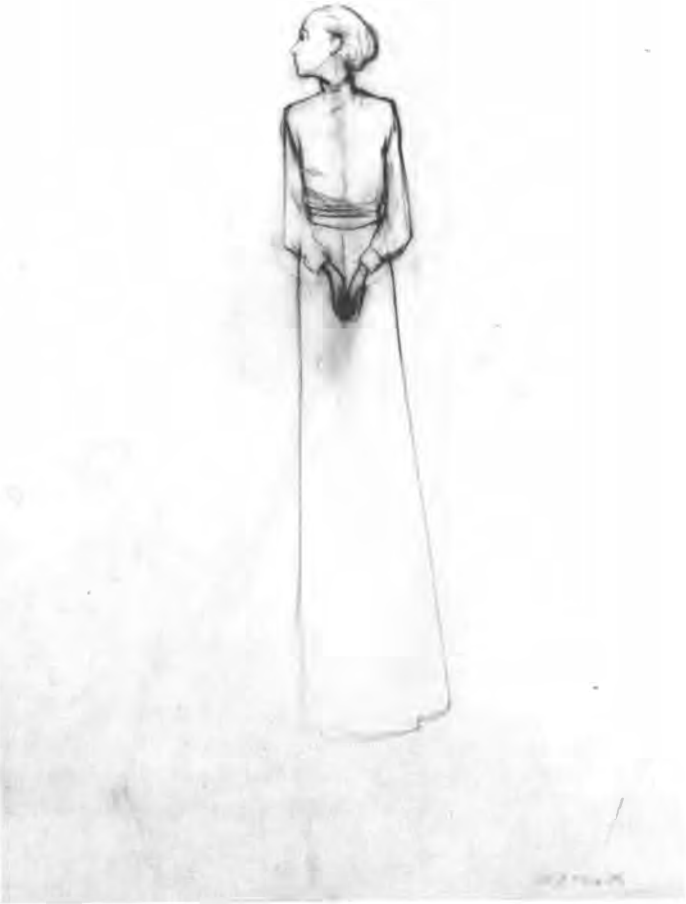
Another hunter once told me that all you really amount to out here is the contents of your bag, the contents of your self, and your gun. You have to concentrate to remember what you are, which is why I have started to write, to help me remember. It's no good just thinking: you have to think "I am thinking!"

Each day – a subtle event at these latitudes – I make an inventory to keep me together, or rather to keep myself apart from things:

> Self: I am called Only Macphew (really!). My best friend is a girl – I call her Miss Miss. I am in love with her but she has no idea, or pretends not to notice. I am a man.
>
> Bag: Two Pencils. One Notebook. One jar. A knife, naturally, with which to skin that blasted hare when it gets too bold. Half a bag of dried banana slices. One one-armed snake. I'll put it with the other one I have at home, if I ever make it back. I'll mount them on L-shaped bits of wood and have them as bookends. That's a cheering thought.
>
> One hole-punch, the cherished possession of Miss Miss which she lent to me a while ago (a burdensome piece of equipment and utterly useless in my current circumstances). I have it with me because I forgot to take it out of my bag before I left, and did not notice the weight due to my jaunty attitude at the outset of the expedition,

My thoughts wander to an erotic meditation on Miss Miss.

I know I must be high up the world, for the flowers are vivid against the dark grey sky, and I hear the noises without causes, tiny musical explosions in the air – a phenomenon that must be perceived to be believed, like



flying fish, of which I have heard sailors speak (and whom I don't believe).

I feel as though I am walking sideways through time, my past to the left of me, my future to the right.

I cannot carry on this way. I must make a choice but won't, for fear of it being the wrong one. I am just continuing, putting one foot in front of the other, hoping for a sign to direct me.

Meanwhile, worst of all, I have started to doubt. I seriously doubt the Noumenon, and wonder if I have jeopardised my life, sacrificed my bones to the anonymous dust of the plain, all for the sake of a chimera. (I imagine that hare will gingerly approach my corpse when it is sure I am dead beyond the possibility of resurrection, and when the flesh has rotted on my fingers, it will take my garnet ring for its collection.)

I doubt the affections of Miss Miss, or that her fatalist self will view my demise as anything other than the course of events. Certain other things have also begun to disturb me: sometimes the flowers don't quite align with their stalks. Why have I never seen the bottom of a mountain? Despite my patient efforts in studying the If'enish language, I have acquired no more than a few words – leaving me to suspect that this argot amounts to little more than gobbledygook improvised for the consumption of the tourists.

And finally I have started to wonder if, beyond the shops and bars and lights of Onomatopoeia, beyond the plane of the gods, where the defunct machines and litter are strewn, underneath the Mountains, and the flowers, and the dust and the bones of the hunters, there is an Island at all?

Theory is Waiting

Gilles Grelet

I

La théorie est attente, établissement de l'homme – du réel sans chair, sans phrase, sans monde – dans la condition de l'attente

II

Le corps de la théorie
– écriture formulaire, enthousiasme ascétique, surrection populaire ordonnée, coque passant bien dans la lame, voile vibrant dans la brise, montant à l'assaut du vent – est institution de l'attente

III

Cette institution – cet acte – est attentat au plein du monde, à la suffisance des mondains, à la morgue des vivants ; attentat par le vide, la distance prise, la parole laconique, défaite, tirée du silence ; attentat angélique, de l'ange qu'est le je sans moi, le corps sans chair, l'acte sans pratique, la formule sans discours

IV

Austère et théâtral, l'acte de la théorie traverse la pratique, ne s'y englue pas : ne fait pas monde. Tranchant de l'aile, du tract épuré, du traité incendiaire, de la joie marine traversant la mélancolie sans bornes

V

Attente instituée, attentat formel, en forme de traversée,
de discernement, d'ordre tranchant, sévère, ardent.
Attentat du je traversant le moi
(écriture en-je destituant les bavardages du moi).
Théorie aiguë, armée.
Théorie-bateau

VI

Les mondains, qui ne savent que les compromis jou(iss)eurs de la terre et du ciel, parlent d'une mauvaise blague, d'une blague qui ne fait rire personne

VII

Théorème d'Anacharsis :

IL Y A LES VIVANTS, LES MORTS, ET CEUX QUI VONT SUR LA MER

Gilles Grelet
Celui Pour Qui Le Monde Est Un Bordel Dont La Pratique Est La Putain Et La Philosophie La Grande Maquerelle

Le 5 juillet 2007

I

Theory is waiting, it establishes man –the flesh-less, phrase-less, world-less real– in the condition of waiting

II

The body of theory
–formulaic writing, ascetic enthusiasm, ordered popular uprising, hull cutting truly through the waves, sail fluttering in the breeze, taking on the wind–
is the institution of waiting

III

This institution –this act– is a full-on attack on the world, on the vanity of the worldly, on the morgue of the living; an attack via the void, the distance taken, via the word that is terse, distraught, dragged from silence; an angelic attack, from the angel that is the I without me, the body without flesh, the act without practice, the formula without discourse

IV

Austere and theatrical, the act of theory crosses practice without getting bogged down in it; it does not become worldly. Incisiveness of the wing, of the purified tract, of the incendiary treatise, of maritime joy crossing boundless melancholy

V

An instituted waiting, a formal attack, in the shape of a crossing,
a discernment, an order that is cutting, severe, and ardent.
The attack of the I crossing the ego
(the writing in I dismissing the chatterings of the ego).
Armed theory, extreme theory.
Boat-theory

VI

The worldly, who only know of pleasant compromises between Heaven and Earth, speak of a bad joke, a joke nobody finds funny

VII

Theorem of Anacharsis:

THERE ARE THE LIVING, THE DEAD, AND THOSE WHO GO TO SEA

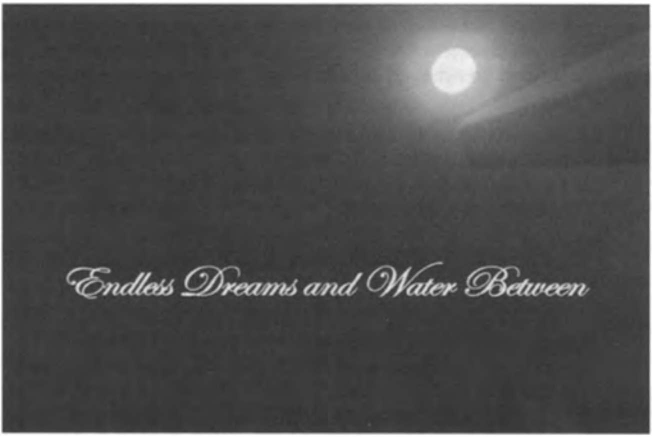
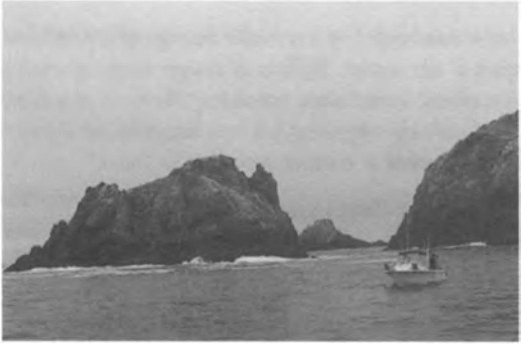
Renée Green's



Endless Dreams and Water Between

Endless Dreams and Water Between

Renée Green



Aria: '*If someone were to tell me I had twenty years left, and ask me how I'd like to spend them, I'd reply: Give me two hours a day of activity, and I'll take the other twenty-two in dreams ... provided I can remember them.*'

****

'*[T]he mind is bombarded by a veritable barrage of dreams that seem to burst upon it like waves. Billions of images surge up each night, then dissolve almost immediately, enveloping the earth in a blanket of lost dreams. Absolutely everything has been imagined during one night or another by one mind or another, and then forgotten.*'

Luis Buñuel

Dreams and Islands

Aria: *'This is to state once again that the essence of the deserted island is imaginary and not actual, mythological and not geographical* [...] *We have to get back to the movement of the imagination that makes the deserted island a model, a prototype of the collective soul. First, it is true that from the deserted island it is not creation but re-creation, not the beginning but a re-beginning that takes place* [...] *It is not enough that everything begin, everything must begin again once the cycle of possible combinations has come to completion.'*

Gilles Deleuze, *Desert Islands*

Raya: '*Islands may no longer be the material prizes they once were, but islands of the mind continue to be extraordinarily valuable symbolic resources, a treasure trove of images through which the West understands itself and its relations with the larger world. Like all master metaphors, the island is capable of representing a multitude of things.'*

John R. Gillis, *Islands of the Mind*

Aria: What is this need to travel? Why are we haunted by it? According to George Sand,

> The fact is that nowhere, these days, is anyone genuinely happy, and that of the countless faces assumed by the Ideal – or, if you dislike the word, the concept of something better – travel is one of the most engaging and most deceitful. All is rotten in public affairs: those who deny this truth feel it even more deeply and bitterly than those who assert it. Nevertheless, divine Hope still pursues her way, assuaging our tormented hearts with the constant whisper: 'There is something better – namely, your ideal!' (George Sand, *Winter in Majorca*)

Mar: In Randa at approximately thirty years of age in 1263, after a dissolute life up until that point, Ramon Llull had a vision of crucified Christ that he took as a sign to dedicate his life to his service. The form of service took three forms: To missionize at the cost of martyrdom. To write a book, the best in the world against the errors of the unbelievers. And to go to the Pope, to kings, and to Christian princes to incite them to create language monasteries for missionaries. Thus he had to travel.

Lyn: On a late summer's day in the year 1608, a gentleman of London made his way across that city. He was a man of ambition, intellect, arrogance, and drive – in short, a man of his age. Like our own, his was an era of expanding horizons and a rapidly shrinking world, in which the pursuit of individual dreams led to new discoveries, which in turn led to newer and bigger dreams.

This man, a ship's captain, was named Henry Hudson.

Aria: From the Convent of Palma in Mallorca, Fray Junipero Serra struggled with his dreams:

> I have had no other motive but to revive in my soul those intense longings which I have had since my novitiate when I read the lives of saints. These longings have become somewhat deadened because of the preoccupation I had with studies.

To recapture the intensity he ventured to the New World to perform an act of self-sacrifice, emulating his predecessors. In 1749 he left Mallorca never to return.

Long before his decision to venture out, there were others familiar with legends of gold. In one romance with the theme of attacks by 'pagan forces on the mediaeval Christians occupying Constantinople', during the battle the pagans were aided by Calafia, a warrior queen who came from a place

> at the right hand of the Indies, an island named California, very close to that part of the Terrestrial Paradise which is inhabited by black women, without a single man among them, who live in the manner of Amazons [...] There weapons were all made of gold. The island abounds with gold and precious stones, and upon it no other metal is found.

Also upon this island 'there are many griffins. In no other part of the world can they be found.' From Biscay to Cádiz, '"California," the lilting name for Queen Calafia's land, was on everyone's mind.'

Aria's Dream
and
First Letter

Dear Friends,

Raya (Raya L. Carlton), Lyn (Sandlyn Ryder Hoving), Mar (Maryse-Françoise d'Île),

It was a dream that stirred me to action.

I dreamt that I lived on a precipice by the sea. The house was made of stone and had spacious terraces surrounding it. Beyond that a garden and beyond that, rows of olive trees in red earth. In my dream I had awakened to find that everything that had previously been troubling me was a dream and that I was free to create and use my time as I wished. I had no financial worries and I could sponsor events to invite esteemed thinkers and creators for one month each year. During these days we would meet for a few hours of conversation, go for a swim, and have wonderful dinners on the terrace at night. Only guests who really wanted to be there would attend. They would be few in number. The rest of the year would be devoted to making beautiful, precise publications and productions.

There would be enough time to realise them without stress.

This dream affected me so viscerally that I perceived it as a signal and began writing this letter to you. Please excuse the group message, but this is a way to begin a conversation by writing to each other. I thought about myself and others I knew. Very skilled and intelligent people, yet not really creating as they could be for various reasons. It was around then that I was reading an odd little book called *A Primer for the Gradual Understanding of Gertrude Stein*, in which I read her words: '*Anything you create you want to exist, and its means of existence is in being printed.*' I adapted that sentence to the present, as also meaning 'diffused via an interface', and I read on:

> After all, my only thought is a complicated simplicity. I like a thing simple, but it must be simple through complication. Everything must come into your scheme: otherwise you cannot achieve real simplicity.

I wondered, "Was Gertrude Stein a Buddhist?" I continued to read:

> A great deal of this I owe to a great teacher, William James. He said, 'Never reject anything. Nothing has been proved. If you reject anything, that is the beginning of the end as an intellectual.' He was my big influence when I was at college. He was a man who always said, 'Complicate your life as much as you please, it has got to simplify.'

Ideally I would like us to explore writing letters. This is something that has become nearly extinct and I'd like to attempt reviving the art of writing actual letters, as I've been reading examples of correspondence from the past. In these letters we can tell each other our thoughts and feelings in more than a few choppy words.

These letters can be sent via e-mail, although I'd like to experiment with sending them by post, so that it is possible to have something tangible we have touched. Actual matter. Let's see if that has any altering effect on our approach to being in contact. One thing is certain, it will require slowing down occasionally to reflect.

I wanted to remind you that each of us live in island locations. Much water is between us, but we can remain close, as I feel we are. Mar and I live on the same island, but in different parts and rarely see each other. I think there is something affecting about this island-dwelling condition and I'd like to think more with each of you about it. My suggestion is to focus more specifically on where we are. I think we are each trying to do this in our own ways. Yet, perhaps we can also be conscious of how the physical location and history of the places we inhabit affect how we currently perceive and engage living in the world, in conjunction with how we can have an exchange between each other. We're not going to live forever. To be blunt, I'd like to think about our lives and I'd like to do this together. We are each unmistakably independent, but now I think it's a good time to use our energies in conjunction for our benefit. Why not? This may sound old-fashioned, but I thought it might be interesting to write about what we read. Remember, reading? As I know you are each readers as well as writers, perhaps this can be fun? Do you ever feel as if you haven't anyone to discuss much with? This is a way to alleviate that feeling. I've been reading George Sand. Does that seem odd? Check out her *Winter in Mallorca*, edited by Robert Graves, when you get a chance. I'd be interested in getting your feedback. Although I'd never previously read George Sand, as I follow her trail I find many fascinating constellations to ponder. ‘Constellations’ is my current keyword.

I’m curious to know what you think about these suggestions. I’d also like your agreement that we will continue to keep up a regular correspondence. You must pledge like in the Three Musketeers: “All for one and one for all.” In addition, I invite you to convene in September with me in Mallorca. Please save up and clear some time. We always plan to get together, but life’s many accidents seem to usually get in the way, so let’s really make an effort. Perhaps we can develop interesting ways to think and create together. I have in mind a form of gathering and publishing that differs from what I’ve previously been involved with, and I’d like your help to think with me, as well as to enjoy being together.

That’s all for now. I hope you are each very well and I look forward to our being in ongoing contact.

Yours,

Aria

Aria Phoenix, in case you’ve forgotten which Aria, as we’ve been so out of touch!

P.S. Lyn you are an Oulipian, Mar, you are an Eulipion. And Raya, you flow like the tides.

Take care!

Aria Phoenix

Aria

Aria is again an editor and now a publisher. She thinks in terms of all that literature has been and can be.

She grew up reading continually and often saw herself in relation to both the characters she read about and the authors she read. Identification of this sort became a concern for her after she'd learned in college that it indicated a naïve relationship to the text and its production. After that she resolved to thoroughly understand this process. She attended Radcliffe Publishing Procedures Course, then still in Cambridge, and immediately began working for a respected publishing house that had been founded, as their colophon depicting a flaming torch noted, in 1817. Thus began her years in book and magazine publishing. She also wrote.

For a time she worked in academia, where she'd landed by chance, via her abilities as an adept editor and manager, with insight regarding intellectual trends.

As a creative contributor she wanted to avoid becoming embedded in the drudgery of administrating. She didn't want her life to be perceived by herself or by others as a path to avoid – the way she'd sometimes thought about her predecessors whom she'd studied and tried to use as models or guides. Often, there were aspects of their lives she'd like to avoid experiencing. She didn't want the same to be observed about herself, so she shifted.

She experienced a moment of conversion and revelation, realizing what she did want to do. That was the beginning of the September Institute. In her travels she met many people, some of whom became friends with whom she has overlapping interests. She decided to write to these three friends and to suggest they begin a project that involved an examination of what they most enjoyed, as well as things they've been curious about. They would write actual letters to each other from their various locations to describe their interests.

Aria reads many languages and is fluent in a few. She prefers to be based in one location, yet she likes to spend time in places to which she feels connected for reasons of friendship, links to her life, and because she enjoys the ways she can feel in these environments. She has an encyclopaedic relation to life. It is important to her that she participate in the relay between what has passed and what is present.

Sandlyn Ryder Hoving

Lyn

Lyn's been a wanderer. What she enjoys increasingly is gaining deep understanding about where she is and where she's been. She returns to places. For her watching films is also a return to sensations she enjoys. Mental links can be made to other experiences. She imagines these moments of fixed concentration as something akin to pausing at the stations of a pilgrimage to remember. The notion of a pilgrimage appeals to her and she's become curious about the enactments and motivations behind such endeavours. Her own travels mirror these. She is very linked to her island, and its many quirks. More than one lifetime would be needed to begin to sound all that resides there.

Even though she'd been away many years, she decided that this location is her home, even though so much had changed and so many people she'd known no longer lived there or were alive. There she felt closer to the fullness of her life, which now interested her much differently than when she'd lived on this island as a youth. She felt as if she now could discover where she could be and where she enjoyed being, without pretence or shame. With so many people gone she felt able to have a different relation to her life and to the island. Her focus includes the long past and the nature of the island.

She continues to work independently, sometimes as a designer. Occasionally, if a book of interest is proposed, she will index it, as this way of creating links is akin to the ways she enjoys probing and thinking about material.

Now she lives near the Cloisters, which seems somehow appropriate for this phase in her life. Her interest regarding the Middle Ages has grown. Yet she thinks about that time in relation to different bodies of water, such as the Indian Ocean. For years she'd been interested in the life and writings of Ramon Llull. She felt she could now go further into her interests.

Maryse-Françoise d'Île

Mar

Mar adapts easily to different environments. She likes to appear to blend into local settings, even places where she isn't fluent with the language. She doesn't like to be a foreigner, even though she can admit her lack of knowledge about the specificity of a place, she compensates by being very curious and receptive to local habits and idioms, as her sense of observation is acute. She learns rapidly, has the humility to accept correction, and others sense her respect for their customs. She is engaged in a lifelong study of herbs and of plants. As these represent knowledge that has been culled over centuries from around the world, her gift of grasping languages and her interest in etymology are put to use in relation to exploring the plant world past and present.

She is independent and used to being on her own since an early age. Travel is common for her, a way of life. Migration of plants is of particular interest to her, as well as the movement of people. Her parents were agronomists. In a way, she continues some of what they did. That recognition accompanies her and comforts her as they are gone. Her focus is on plant life, their properties and their beauty, that can be observed as well as represented.

She's comfortable in crowds, in markets, in rural and urban settings, and especially by the sea. Her preference is for a base near the water in a modest house in nature. For this reason she's deeply inspired by Lester Rowntree's way of life, based on what she's read about her in her book, *Hardy Californians*. In particular, she often thinks of this phrase of Rowntree's self-description in relation to how she sees herself: '*A wayfarer urged by conjectural curiosity.*'

Raya L. Carlton

Raya

Raya is extremely intelligent, yet often perplexed by what people say and mean. The differences between what people say and what they mean confuse her, as she imagines these to be synchronous acts, yet via experience she's learned otherwise. She is attracted to organisms in nature, particularly water varieties of fauna and flora. They can have surprising traits. Appearance and encounter can contradict. This contact allows her to form analogies to life situations, growing out of her increasing knowledge of underwater habitats and creatures.

Born inland near a Great Lake, she had an early desire to be near water. She won a scholarship to study at an institute for oceanography on the Pacific coast. Many years have passed and she continues to observe and investigate the waters and the shores.

She prefers being with one person she feel close to. She avoids crowds. She also feels good in small gatherings of people she knows she can trust and whom she feels close to in some way. Sometimes a person will make a statement that she will ponder for years. Her mind works to attempt to search in the world for evidence of what was mentioned, so that she can mull over and decide what she thinks about what was posited. The statement is usually a casual one, yet for Raya it may loom large with potential content, a sort of key that may open an aspect to living that seems distant to her.

She is quite at ease on her own, walking along the shore, or wading in tide pools.

Water, Time and Islands

Aria: ‘*In every country the Moon keeps ever the rule of alliance with the Sea which it once for all has agreed upon.*’

The Venerable Bede

Aria: ‘Continental islands *are accidental, derived islands. They are separated from a continent, born of disarticulation, erosion, fracture; they survive the absorption of what once contained them.* Oceanic islands *are originary, essential islands. Some are formed from coral reefs and display a genuine organism. Others emerge from underwater eruptions, bring to the light of day a movement from the lowest depths* [...] *Continental islands serve as a reminder that the sea is on top of the earth, taking advantage of the slightest sagging in the highest structures; oceanic islands, that the earth is still there, under the sea, gathering its strength to punch through to the surface. We can assume that these elements are in constant strife, displaying a repulsion for one another. In this we find nothing to reassure us* [. . .] *In one way or another, the very existence of islands is the negation of this point of view, of this effort, this conviction.*’

Gilles Deleuze, *Desert Islands*

Dear All,

This is an immediate follow-up. I realize you haven't had a chance to respond yet, but I wanted to send this off to you as I'm eager to read your initial thoughts.

The basis for the ideas of what I'm calling the September Institute is in a separate description that you'll soon receive. I'm thinking about a project that can rely on our various strengths, or as I've heard stated recently, 'skill sets'. The focus continues to be on locations we inhabit, yet that seem exotic for those who aren't familiar. As a future long term project, I propose creating an *Island Encyclopaedia.* This is an impetus to shift our thought into different kinds of associations, for example, beyond the assumed acceptance of continents or nations. These concepts are up for questioning in any case. We've talked about some of these things before, so why not enact them? First of course, we have to get the letter exchange going. Please excuse my enthusiasm, but I feel as if a weight has been lifted from me since I had a kind of 'conversion' experience. I promise not to attempt to convert any of you. I already like you. But we are all seekers.

To follow up an earlier wish, has anyone yet read George Sand? *Winter in Mallorca*? Please do! I'm beginning to read her *Story of My Life* (*Histoire de ma vie*), a very unusual approach, as she begins the story at least forty years before she's born, which I like. There are many biographies, most of them are annoying, but some are interesting. I come across all sorts of curious descriptions of writing women when I read Sand-related books. It's still fascinating to me that Sand was penalised for what were considered her excesses. Here's one instance, from Belinda Jack's *A Woman's Life Writ Large:*

> For Nietzsche, Sand was a prolific, ink-yielding cow, an example of 'lactea ubertas.' Her overflowing, undisciplined writing was evidence of her incapacity to reason logically […] [H]e likened her to Wagner. What disconcerted both Baudelaire and Nietzsche above all, beyond or beneath their more rational objections, was Sand's passion, her energy, and her capacity to respond with enormous courage to conviction. These same attributes account for her enormous popularity.

I'm also reading her *Lettres d'un voyageur*, which provide another perspective. Sand's correspondence is impressive. It is still being edited. There are twenty volumes to date. She was a precursor to the open letter, in writing letters to be read publicly. As she said, '*I felt I had many things to say and that I wanted to say them to myself and others.*' Take this as an encouragement. As Henry James put it – interesting how this is the second mention of one the James family – George Sand '*is open to everything*': her discourse might be '*amatory, religious, political, aesthetic, pictorial, musical, theatrical, historical.*' It might also be, as we see in *Lettres d'un voyageur*, botanical, astronomical, mythological. In fact, about almost anything that seized her interest and imagination she was remarkably knowledgeable.

Alright friends, I'll leave it there. As always, looking forward to hearing from you.

Yours,
Aria

Humans and Islands

'[H]umans can live on an island only by forgetting what an island represents.
Islands are either from before or for after humankind.'

Lyn

Dear Aria,

cc: Raya, Mar

I like your idea very much. Count me in. I pledge allegiance to the experiment.

Shall I begin now?

I do feel as if I have been saving many words. I don't really talk with many people, beyond those I encounter while doing errands or in a professional capacity. Not speaking hasn't bothered me, as I write, but since you mentioned it, yes, there are few people now here to speak with about what means something to me, beyond politics and the economy. Is it generational? So many people are gone even though we're not what I used to imagine as old. We were described by the media as Generation X, remember? It figures: no name, just a letter. In the 1920s some advertising type coined the phrase 'lost generation' and later during 1970s punk times, 'blank generation.' It's kind of ridiculous to even consider being branded by a time period, don't you think? Now there is a 'Gen X' President elected in the US, and youth have hope. Really? Yes, let's write about our lives and about where we are.

To begin, here's a dream I'd written down many years ago, before I'd been anywhere farther from this island and this country than Mexico:

> This is the second time in a row that I have dreamt about water. Two nights ago I dreamt about the Mediterranean Sea and a Greek island named Pesta. The dream was related to Atlantis, the city that sunk into the ocean. Last night I dreamt about travelling outside of one's body. I dreamt of the Brontë children dying, but not really being dead. A small boy suddenly died, but his corpse was not buried. Within a few days it did not rot. I saw him breathing as if asleep. He opened his eyes and sat up. Said he had been on a voyage beneath the sea.
>
> Many of my friends were disappearing and I could not find them. They returned telling me that they were in another dimension, beneath the sea. Several of them said that suddenly they were able to go to a place in the depths of the ocean. They were going to have a party there and asked if I would come. I wanted to know the secret of how they were able to go to this deep place. One gave me a very tiny submarine, smaller than my smallest finger, and told me to climb in. I just held it, not knowing how to use this submarine. I looked out of a window, which came to the water's edge. I wondered what would happen if I were to jump in. Would I develop fins on my neck for breathing the farther I sank? Would I find this secret buried place?

When I had been on the road the first time, years ago, I'd gotten physically familiar with different places.

By foot I walked in Oklahoma, past an Indian reservation along with an occasional lone Indian, who didn't even try to hitch a ride. For three days I waited at a truck stop for a lift East. I never got it.

Walking became a mode of transportation then. Although my friend Voy's scam got me on a plane and out of there.

Since then I've become familiar with places by walking in them, learning them by foot. Figuring out routes I prefer based on invented reasons of taste. Not enough trees on this street. Depressing buildings on that street. The grade of this hill is more gradual. In many cities, towns and villages, in different countries, I've walked. Walked and worked. And also just walked, watched, listened.

Eventually I lived in a place by the water. It had seven hills and I walked each of them and stared at the water when I'd reach the top. I took ferries across the water and continued to walk. Sometimes I rode buses to the beach and walked the long shore.

Now islands. I never really thought of myself as being particularly fond of islands. But you're right, I do live on one. It had even been called, as well as thought of itself as, 'the island in the centre of the world' – how about that for megalomania? It does seem to be a tendency that has affected different locations at various times in history. Since I've been back I've become quite interested in finding out more about this island and its past. I've also become very interested in studying the Middle Ages. Maybe these interests are strangely related. In part they derive from the fact that I now live on the only part of the island that has areas with its earlier vegetation and rock formations, and this location is near that odd importation of the European past, the Cloisters. In addition, I've been trying to enter the thoughts of a mediaeval mystic and philosopher from Mallorca, Ramon Llull. Perhaps you can help me from your location? The island I inhabit is indeed a mysterious island, but all of our locations involve combinations. I've been thinking about Llull's *Ars combinatoria*, in relation to living. Perhaps it gives some indications of value in the present, even if it's challenging to decipher thoughts from a medieval Christian mindset. But certain ways of working with permutations are related to computer science. He is also considered by Oulipians as what they call an anticipatory plagiarist.

I think one of the attractions to me of the Middle Ages is that it was necessary for some to keep ancient knowledge alive. The primary protectors of received knowledge at that time were Islamic. This, I'm sure, resonates with your own interests in your Mallorcan island, as there are many traces in place names and in surviving structures of an Islamic past.

Al-Mayurka, is this the correct name? What was Mallorca before? And what was Manhattan before, during those earlier times? Before maps and fixed boundaries? Before passports?

This island region had a confederacy called Iroquois, that dated back at least nine thousand years. It was a complex of islands. Algonquins were called 'The First Peoples' of North America and had at one time covered a third of the continent. Most of the peoples that passed through the area were related to the Lenape, described as 'an ancient riverine people of Algonquin stock.' They can be perceived as comprising hoops or circles within circles of other related peoples. Munsee people were the last to predominate.

The Mohican descendents of Algonquins are more well known, but they were also called 'People of the River.' I read that there are 18,000 skeletons of Native Americans hidden in museum storage, of different museums like the Peabody Museum, for example.

Menatay means island to the Unami Delaware. Mahatuouh, 'place for gathering bow wood' to the Munsee. Manhattan or Manahatta, 'rocky island', add the 'ten' and that means habitation in Munsee. So Manhattan is the Munsee name.

I'll stop now and see if I have any messages or post from any of you. I picture messages in bottles moving through the sea. We could start a blog, but that would defeat the purpose of intimacy and depth, I think, at least at this phase.

Looking forward to continuing.

Yours,
Lyn

Al-Mayurka
Mallorca
Mar

Dear Aria,
cc: Lyn, Raya

Thank you for your letter and invitation. Maybe we'll be in touch differently. Yes, I will participate in a correspondence. It has been a long time since I've written the kind of letter you describe.

While thinking about your proposition I came across a letter in a novel I'm reading. The letter is meant to have been written by a priest and it launches the novel *The Dolls' Room*, by Llorenç Villalonga. It is set in a fictional Mallorcan town called Bearn, which is also the name of the founding family that is dying out. The letter is dated 1890, but the book was published in 1956. I'm reading the English translation, which didn't appear until 1988, after the author's death. He was born in Palma.

This may interest you. In a way it relates to the issue of generations that Lyn mentioned and change to which you allude. I quote:

> The question is not a simple one, and I feel the need to start from the very beginning. Giving you all the details of that life I loved so deeply, despite its grave errors, has provided a solace for me in my solitude. I must admit that the motive of my story, written in the course of these endless nights, may not be solely the scruples of my conscience, but rather the pleasure of reviving the familiar venerated figure I have just lost. With him an entire world has disappeared, beginning with these lands that have seen my birth and that will have to be auctioned off because the creditors have already notified us that they do not wish to wait any longer. The Senyor's nephews and niece neither have enough money to pay off the mortgages nor feel any love for Bearn, being used to city life as they are. There might be one last source of hope: they say a relative of the Senyors has arrived from America after having become a millionaire selling cardboard boxes. It seems unbelievable that anyone should become an important personality selling little boxes, but he has introduced himself with much pomp, laden with gold and determined to dazzle all of Mallorca with an electric automobile that has already killed two sheep. On his calling card, below his name, are the words Cardboard Containers, which no one quite understood until they realised it referred to those famous boxes.

I'll skip ahead, the quote continues:

> To me, halfway down the path of my life, this Cardboard Container Bearn would be nothing but an intruder. Yet there is no question but that a new generation is emerging, which is willing to associate these old lands with the personality of an outsider and will experience the same feelings towards the union of senyor and lands, which it will believe to be deeply rooted, that I felt towards Don Toni as a child.

For some reason, after reading this I thought about Robert Graves and Deià, all the changes in that area. I have also been reading George Sand's *Winter in Mallorca* and I took notice of the many footnotes, written by Graves, contesting nearly everything she wrote. It was quite remarkable. I was somehow reminded of Kinbote's role in Nabokov's *Pale Fire*. We've had some laughs over that. Some of these notes extend for pages on their own, as if he's taking over her book. It's quite weird. I realise I wasn't born on this island, although now I feel as if I had been, since I've been 'adopted' by a very kind family. I have become familiar with the vegetation and landscape over these years and I must say that Graves seemed rather harsh on Sand. That made me wonder what had been his experiences? He gives the appearance of being omniscient regarding anything Mallorcan and it seemed as if he'd perhaps had his own story with another woman who was also a writer. Through reading, I found this was the case. Two poets together. He lived in Deià with the writer Laura Riding. They had even founded a press together. Isn't that interesting? Of course you probably know all about this. There are even books in English on their years together, which were 1926 to 1940. Strange, isn't it, what become the remnants of a life and what people who have the possibility to publish choose to remember? Concerning both Robert Graves and Frédéric Chopin in Mallorca, we didn't yet discuss how Graves seems to identify with the male artist, composer and pianist Frédéric Chopin, who spent the winter in Mallorca with Sand – according to her, in a sickly state. Graves and Chopin are considered cultural monuments, whereas Riding and Sand are not. I haven't yet found statues of either of them. They're seen more as extreme, crazy and witchlike, from what I've gathered in conversation and through books.

The photos of Laura in Deià are particularly unflattering. In the early days she was considered to be as beautiful as a movie star. Of course, I prefer to read what she wrote rather than focus on the personal drama. But yes, thanks also for the Polti suggestion. I'll check out the thirty-six dramatic situations.

I have been enjoying reading *Winter in Mallorca*. It's pretty easy to find here in many languages. As it's such a tourism product I'd never felt compelled to read it until you suggested it. Sand describes a challenging situation in an unfamiliar place known prior to her journey only through painted images and travelogues. In some cases I disagree with Sand and Graves. But it is an interesting read. It makes me more curious about aspects I've been investigating concerning the Islamic past, via botany, gardens and architecture. It's been an extreme pleasure to encounter the small painted illustrations in the old herbal botanicals. Even though the classification systems have been contested, there is much to be found there. That's a possible direction I'd be interested in developing.

In terms of my research I have found sources focusing on the Balaeric Islands. This has something to do with your request that we think more about where we are. One of the particular aspects we face as islanders concerns scale. There are rare species of flowers here, but they may grow only in a small area. They may be the only examples of their sort in the world. There is no elsewhere beyond these island locations for certain plants. They are not endlessly replenished. I've read that 'the near-disappearance of Minorca's *Vica bifoliolata* can be blamed on collectors of rare plants.' Luckily with photography plants can be 'collected' in photos, rather than killed.

So I've been busily engaged. I'm curious to read more from each of us. The letter exchange is a good idea. Aria, it would be wonderful to see you sometime, even before September. Let's visit? To Lyn and Raya, I look forward to being in contact via post and hope to see you soon.

That's it for now.

Yours,
Mar

Yerba Buena
San Francisco Bay
Raya

Dear Aria,
cc: Lyn and Mar

It's great to receive a letter from you. I'm glad to resume contact and I look forward to participating in the correspondence with you, Lyn and Mar. Thinking from the islands we inhabit is an interesting way to begin locating our various intersections and yes, thinking of constellations can be a stimulus. It's been ages since I've written an actual letter to anyone, especially as nearly everyone I know communicates very succinctly via e-mail and in code.

To begin, I want to use words that I like. They remind me of your invitation:

> I want you to hear these words. Now I am speaking to you about our lives.
>
> That is the way we begin speeches in Cherokee, and then we say what we would like to see happen, with a simple statement that begins with "I want," as in "I want us to go

> to Washington and tell them just what's going on down here." The way white people exhort in their speeches – such as "we should …" or "we must …" – sounds to us not only arrogant but devious. Is this guy trying to hide from us his own thoughts? Then why speak? (They often do speak only for the purpose of hiding their thoughts.)

This was from *Those Dead Guys for a Hundred Years* by Jimmie Durham. I've liked those words for a long time and it's great to be able to share them.

I'm surrounded by water, which I enjoy, and I spend most of my time moving through or around water and shores checking the habitats and studying different aspects of what supports life. As I drive to work I see water and other islands, as San Francisco is technically a peninsula, although it feels like an island as it is an archipelagic region and there are, I believe, forty-one islands in the vicinity of the San Francisco Bay, leading out to the Pacific Ocean.

I, like Lyn, imagine what existed before. I think about long spans of time, millions of years, and what was here before and before and before, as I keep finding traces of the past when I walk along the shore. The life forms are also ancient. They survived all kinds of turbulence and adapted to the changes. In this region there is much awareness of the intensity of the earth, as we're on an earthquake fault. The San Andreas Fault, which is actually a network of faults, that converge near where I spend a lot of time, around Bolinas Lagoon. All of the faults have shown tectonic activity, meaning that the North American and the Pacific Plates shift. One of the things I find so fascinating about the area is that two distinct provinces from different geological time periods are now juxtaposed because of the movement of earth. One observer described the aerial view:

> Looked at from the air, the Point Reyes Peninsula seems about as disjunct from the rest of California as Saudi Arabia is from Africa, and for the same reason: a boundary of lithospheric plates.

Witnessing the strength of the sea and the changing climates is unavoidable here. Watching the waves I often think of the distances they travel. For example, seismic waves, called tsunamis. It's impossible not to think of islands in relation to these. Unlike larger landmasses islands, as Rachel Carson tells us,

> are the result of the violent, explosive, earth-shaking eruptions of submarine volcanoes, working perhaps for millions of years to achieve their end.

As she notes:

> It is one of the paradoxes in the ways of earth and sea that a process seemingly so destructive, so catastrophic in nature, can result in an act of creation.

Forces that occur in the depths of the ocean are fascinating and these processes continue, as they have for millennia.

Yet there are moments of human intervention. One island I see often is Alcatraz. I found a book called *Alcatraz is not an Island*, published in 1972. I quote:

> Alcatraz was born a mountain, surrounded by the waters of a great salt sea. [...] We send out our voices to that desolate rock, and are gifted with echoes which resound our strength.

It was reclaimed by Indians of All Tribes in 1971, but it was taken away again by the invaders, yet it's a strong symbol for me. I remember everyday. The Spanish named it Alcatraz as it was once inhabited by many pelicans. It remains a wish to see the prison concrete and steel removed and a regeneration of long gone pelicans, vegetation and wild flowers.

From this island area in this state that was once perceived to be an island, how do I inhabit this place? It's been interesting to begin reading George Sand and to attempt understanding her context. Wars were quite constant in Europe before her birth and through her life. I think about that here, as this nation is still at war. The rift between the rich and the poor is wider than it was before 1981. Prison expansion as a private industry has been growing and California is notorious for its number of prisons and number of incarcerated people. I think about these things here, as there continue to be reminders, like Alcatraz. To balance that, there is the sea and the long histories.

I do experience more dreamy states of mind while reading and drifting. Wet sounds of steadily falling rain and of spinning car wheels. These are common during winter in northern California. This was what I heard as I began reading letters written by George Sand to someone named Marcie.

Writing is a bit like dreaming. Thoughts and memories swirl in and out of my mind, like a fog that I can see from a distance and watch gradually swirl in, engulf me and my surroundings, then shift again and go elsewhere. What one tries to put into words can seem dense and difficult to grasp, and like fog it's full of tiny drops of water-like thought, sometimes feeling colder depending on its density, yet it reflects many degrees of light.

Looking forward to continuing. I'm sure more words will come.

Yours,
Raya

Cycles

Another Letter from Aria

Dear Lyn, Mar and Raya,

Thank you so much for your positive responses to my wish. It makes me very glad that we are all in this new form of contact.

Did I mention to you when I was last at the Big Book Sale in San Francisco I found books by women on writing from the early 1980s and early 1990s? It was like discovering items from a time capsule, as they seemed to exist in a very distant past.

Now that we've begun our correspondence I have many things I'd like to respond to regarding what you've already written and in turn, write more ideas that your words have stimulated. There never seems to be enough time. So let's begin planning to convene.

I'd like to mention more on Georges Polti, regarding the Middle Ages, as well as think through William Morris with you. There are interesting possibilities brewing for developing the *Island Encyclopedia.* Also there's more to follow up concerning Laura Riding and her renunciation of poetry, and her quest for linguistic truth. It will take years for us to read George Sands's oeuvre, which I continue to do. I'm reminded of a story by Hollis Frampton. It described a person who'd been filmed from birth and had to watch all of the films until death. I know I've misdescribed this, but the point is that to read what Sand wrote could take a lifetime. Could that be a reason why her works have been dismissed? A resentment at its sheer enormity, that can be presented as excess? Anyway, there are pearls there.

Here are some initial thoughts I've written regarding the September Institute. These are up for discussion, so I look forward to your feedback.

I listed four mottos:

1. We still own our words and can produce them.

2. Anything you create you want to exist, and its means of existence is in being printed.

3. Sending transmissions from dispersed islands, linking worlds, time and space.

4. We continue the ongoing movement of combination people.

September Institute compiles and regenerates material from abandoned collections and publications, providing indexical access and linked research tools, that enable circulation within the depths of significant ideas, operations, and productions of those who may have been forcefully forgotten. S.I. publishes out-of-print books to give them new life.

September Institute is not a utopian community, but rather a momentary nexus. It exists in contrast to previous idealist attempts to address shifting contemporary moments. Acknowledging the predilections of the past (idealist, romantic, utopian, and modernist aims), S.I. embraces the present, however it is calibrated, in relation to time, with a consciousness of time's expanse.

Beautiful and odd remnants from the expanse of time are excavated, represented and re-thought. These include books, ephemera, notebooks, photos, and out-of-date time-based formats, i.e. pre-digital. They are evidence of encounters, a trace of experience. S.I. produces books of collected data. Online versions also exist.

Please let's continue thinking and exchanging.

I love words. Etymologically, texturally. It's possible to enter words on one's own. As each of us can enter the letters we've exchanged on our own. Examining each other's thoughts separately. This process of exchanging and learning about each other's thoughts through letters is a bit like learning about words. Becoming familiar with the vast range of nuances possible, of words and thoughts, is like entering a secret or monastic order. Very few people care about words or thoughts in this way. It's the way things are. I find comfort in this exploration though, perhaps because it's specialised rather than standardised knowledge, which is so abundant. Writing letters to each of you is different than writing for a blog, in the sense that this is a specific activity between four people, even though I do like the Disgrasian™ blog, but this is different. How to translate past feelings, times, and histories into meaningful comprehension that can provide fuel amidst present feelings of lack and absence? Was it always this way? I wonder about life before our presumed extreme technological connectivity and presumed availability. I wonder how you feel and how others have felt. Probing these things has motivated this correspondence. The wish for something else that might be possible. More profound understanding, for example. Other kinds of meaning. I do care about depth and varieties of meanings, as I care about combinations and permutations, as we've discussed.

Autodidacticism can be extremely fulfilling, especially when so much can appear to be a wasteland. This doesn't mean that I'm interested in retreating, but rather I feel my senses available to engage are sharpened as I can choose a more exact way of articulating or conveying them, in words, images, sounds, etc. I respect and admire each of you for also sharing these interests.

Since so many specialised skills, things, and people are slipping into oblivion, my interest is more and more in what is specific and perhaps thought of as esoteric. What is determinedly unfashionable. This interests me. Maybe some things are too difficult to reproduce, because there is no facility, concentration, or interest that enables easy reproduction. I'm not endorsing 'craft,' as it's recently been labelled. This is not my interest. I'm also not suggesting difficulty for the sake of difficulty, nor am I assuming that specialty can be equated with superiority, yet still, I wish to probe life's complexity.

And I'm glad that each of you is also willing to do this.

I'll conclude my letter with something to ponder, as it relates to what I've written. We can wonder with Henri Bergson and Gilles Deleuze:

> [W]hy something rather than nothing, but why this rather than something else? Why this tension of duration? Why this speed rather than another? Why this proportion? And why will a perception evoke a given memory, or pick up certain frequencies rather than others? In other words, being is difference and not the immovable or the undifferentiated, nor is it contradiction, which is merely false movement. Being is the difference itself of the thing, what Bergson often calls the *nuance*.

I'll leave you with those words until the next time. From each of our islands let's stare at the moon.

Yours,
Aria

Notes on Contributors and Acknowledgements

Charles Avery is an artist who works with a range of media. Born in 1973 in Mull, Scotland, Avery now lives and works in London. He has exhibited internationally, with recent solo exhibitions in London, Edinburgh, Geneva and Turin, and was featured in the 2009 Tate Triennial *Altermodern*. Avery is represented by doggerfisher, Edinburgh and Pilar Corrias, London.

Angela Detanico and Rafael Lain are artists living in Paris and São Paulo. Their practice investigates possible new configurations within pre-existent systems, such as cartography and written language, in different media as typography, video, sound and installation. Their work has been exhibited internationally, and in 2007 they represented Brazil in the 52nd Venice Biennial. They are represented by Galeria Vermelho in São Paulo and Martine Aboucaya in Paris.

Stephen Emmott is Head of Microsoft's Computational Science Research, leading an international, multi-disciplinary research effort focused on accelerating fundamental advances in science in areas of societal importance, but where current scientific approaches continue to pose barriers to such advances. A neuroscientist, Emmott's scientific career spans research positions at The Centre for Computational and Cognitive Neuroscience, University of

Stirling; AT&T Bell Laboratories; chief scientist of NCR's advanced research; and University College London. He is also Professor of Computational Science at Oxford University.

FIELDCLUB was initiated in 2004 as a live research project based on a four-acre field in Southwest England. The project collaborators seek to deconstruct and re-codify the post-modern notion of 'self-sufficiency' through interdisciplinary art practice and direct interaction with the land. Inquiries include: The nature of progress as contingency, origins and expansion of the human niche, Biospheric/Technospheric interrelations, land as capital, and the indexing of sentimentality and function.

IAIN HAMILTON GRANT is Senior Lecturer in Philosophy at the University of the West of England. He is the author of *Philosophies of Nature after Schelling* (Continuum, 2006) and of numerous articles on Kant and post-Kantian Idealism, philosophy of nature, philosophy of science and technology, and contemporary philosophy. He is currently working on a book entitled *Grounds and Powers.*

RENÉE GREEN is an artist, filmmaker and writer. Via films, essays and writings, installations, digital media, architecture, sound-related works, film series and events her work engages with investigations into circuits of relation and exchange over time, the gaps and shifts in what survives in public and private memories as well as what has been imagined and invented. She also focuses on the effects of a changing transcultural sphere on what can now be made and thought. Her exhibitions, videos and films have been seen throughout the world in museums, biennales and festivals. A retrospective exhibition of her work, *Ongoing Becomings 1989-2009*, is currently on view at the Musée Cantonal des Beaux-Arts, Lausanne.

Gilles Grelet is director of the series *Nous, les sans-philosophie* (Paris: L'Harmattan) and author of around thirty publications, articles, films and papers in France and abroad. Most recently he published *Citations pour le président Sarkozy* (with Juan Pérez Agirregoikoa; Paris: Editions Matière, 2009).

Manabrata Guha is Assistant Professor at the National Institute of Advanced Studies (NIAS), Bangalore, India. His research work focuses on 'future war', network-centric warfare, and counter-strategic theories of war and combat. He is the author of *Re-Imagining War in the 21st Century: From Clausewitz to Network-centric Warfare* (London: Routledge, forthcoming 2010).

Owen Hatherley is a freelance writer, working mainly for *Building Design*, *Icon* and *New Statesman*. He is researching a thesis at Birkbeck College, London on the political aesthetics of Americanism, and is the author of *Militant Modernism* (Zero, 2009).

Nicola Masciandaro is Associate Professor of English at Brooklyn College, CUNY and a specialist in mediaeval literature. He is the founder of the journal *Glossator: Practice and Theory of Commentary* and the author of works on labour, the animal/human boundary, the hand, individuation, deixis, Aesop, sorrow, mysticism, Dante, decapitation, and metal. Current projects include: *The Sorrow of Being* (monograph), two co-edited essay volumes (commentary, speculative medievalism), *dESIRE Gloss* (a collaborative commentary on Kristen Alvanson's dESIRE project), and *Hideous Gnosis: Black Metal Theory Symposium.*

GREG MCINERNY is a post-doctoral researcher at Microsoft Research, Cambridge, in the Computational Ecology and Environmental Science group. He is an ecologist researching the ecological responses of natural populations to global change and the necessary predictive tools. His research has yielded novel insights into the interactions between ecology and evolution during climate induced range shifts. Greg has also explored some of his interests in the interactions between science, culture and history in the '(En)tangled Word Bank' project which visually documented textual selection through six editions of the *Origin of Species.* Born in the UK, Greg holds a PhD in Ecology and Evolution from the University of Leeds. http://research.microsoft.com/en-us/people/gregmci/.

TIMOTHY MORTON is Professor of Literature and the Environment at the University of California, Davis. He is the author of *The Ecological Thought* (Harvard, 2010), *Ecology without Nature* (Harvard, 2007), seven other books and over sixty essays on literature, ecology, philosophy, and food.

REZA NEGARESTANI is an Iranian philosopher. He is the author of *Cyclonopedia: Complicity with Anonymous Materials* (Melbourne: re.press, 2008).

Drew Purves is is a permanent research scientist in the Computational Ecology and Environmental Science Group, a part of the Computational Science Lab at Microsoft Research Cambridge. He studied ecology at Cambridge University, did a PhD in ecological modelling at the University of York, and spent nearly six years as a postdoc in the Ecology and Evolutionary Biology Department at Princeton University (working under Prof. Stephen Pacala), before joining MSR Cambridge in 2007. His research, which focuses on the dynamics of populations and communities of plants, especially forests, has led to around 20 publications in peer-reviewed journals including *Science*, *PNAS*, *Proc Roy Soc B*, *Global Change Biology*, *Ecology*, *Ecological Monographs* and *Ecology Letters*.

Eyal Weizman is an architect based in London. He studied at the Architectural Association in London and completed his PhD at the London Consortium, Birkbeck College. He is the director of the Centre for Research Architecture at Goldsmiths College. Since 2007 he has been a member of the architectural collective *Decolonizing Architecture* in Beit Sahour/Palestine. Since 2008 he has been a member of the board of directors of B'Tselem. Weizman has taught, lectured, curated and organised conferences in many institutions worldwide, and is the recipient of the James Stirling Memorial Lecture Prize for 2006-7.

Rich Williams is is the head of the computational ecology and environmental science group at Microsoft Research, Cambridge. Rich was educated as an engineer and physical scientist, and has a PhD in physical oceanography. Before coming to Microsoft Research in 2006, Rich worked as a freelance software developer and scientist. His research focuses on understanding ecosystems as complex networks and on the robustness of the dynamical systems supported by those networks.

CONTRIBUTORS: **Charles Avery, Angela Detanico and Rafael Lain, Stephen Emmott, FIELDCLUB, Iain Hamilton Grant, Renée Green, Gilles Grelet, Manabrata Guha, Owen Hatherley, Nicola Masciandaro, Timothy Morton, Greg McInerny, Reza Negarestani, Drew Purves, F.W.J. Schelling, Eyal Weizman, Rich Williams.**

As far as we know, philosophical thought, indeed thinking as such, occurs only on one planet. **Collapse VI: Geo/philosophy** asks how, as products of the Earth, philosophers, scientists and artists have attempted to encompass it in thought; and how the philosophical enterprise of thinking 'the whole' is determined by our planetary horizon.

Collapse VI brings together philosophers, theorists, eco-critics, leading scientific experts in climate change, and artists whose work interrogates the link between philosophy, geography, ecology and cartography, in order to create a portrait of the present state of 'planetary thought'.

Editorial Introduction

Robin Mackay and Reza Negarestani

Cookery has never been so high on the agenda of Western popular culture. And yet the endlessly-multiplying TV shows, the obsessive interest in the provenance of ingredients, and the celebration of 'radical' experiments in gastronomy, tell us little about the nature of the culinary. Is it possible to develop the philosophical pertinence of cookery without merely appending philosophy to this burgeoning gastroculture? How might the everyday, restricted sense of the culinary be expanded into a *culinary materialism* wherein synthesis, experimentation, and operations of mixing and blending take precedence over analysis, subtraction and axiomatisation? This volume, drawing on resources ranging from anthropology to chemistry, from hermetic alchemy to contemporary mathematics, undertakes a trans-modal experiment in culinary thinking, excavating the cultural, industrial, physiological, chemical and even cosmic grounds of cookery, and proposing new models of culinary thought for the future.

Proto-scientific thought and experimental practice, particularly in the form of alchemy, was linked to the culinary arts' vital engagement with the transformation of matter. Indeed, how could empirical inquiry into nature, seeking to determine the capacities of matter on the basis of what lay to hand (see Bacon's recipes in the Appendix), be anything other than a culinary endeavour? Yet with the increasing specialisation of the sciences, philosophy has misplaced its will to extend such inquiry into a speculative philosophy whose power resides in its synthetic ambition as well as its analytical prowess.

As observed by **Iain Hamilton Grant** in the interview which opens the volume, it is chemistry's retention of this synthetic ambition that recommends a 'chemical paradigm' for thinking, providing the opportunity for philosophy to step outside the circle of a 'critical' method according to which the conditions of possibility for a thinking of nature are purely epistemological. In the thought of the nineteenth-century naturephilosophers on which Grant draws, the production of 'nature' qua thought-system cannot itself be excluded from the chemical syntheses it discerns at work in the inorganic realm; and thought as much as matter must be subjected to an experimental regime.

Human thought, then, does not condition the powers of chemistry; nevertheless, the latter are mobilized in unprecedented fashion by the former. Under the influence of modern chemistry, indissociable from the industrial exigencies that have driven it, synthetic production – in the culinary as in other spheres – proceeds to reprocess the nature that produced it. Augmenting the modest chemical capacities bequeathed to the human animal by its evolutionary history, it has produced a new 'chemical earth' upon which we graze, without having fully encompassed in thought the prospects that its deterritorialization opens up to us.

Exemplary in this respect is **JOHN GERRARD AND MICHAEL A. MORRIS**'s 'Corn Bomb', which traces the implication of nitrogen in the industrialised alimentary regime, and the way in which the ingredients for postwar human culture were prepared and 'cooked' by war and petropolitics, bringing about a new planetary economy whose massive ramifications are yet to be fully comprehended. This story of the entanglement of military force, agricultural expansion and industrial science provides a backstory to Gerrard's portraits of austere, functional structures located in desolated landscapes, symbols of the virtual climate of power that the industrialisation of the chemosphere has made possible.

Extending Gerrard and Morris's 'local' history of nitrogen, which begins with the human harnessing of chemical powers, into the distant past, we realise that the preparation of food in fact takes place on a planetary and even cosmic scale. The superficial landscape of mass-produced corn and meat that Gerrard and Morris correlate with the contemporary human condition is a non-trivial section of a deeper chemical history: 2.8 billion years ago, cyanobacteria emerged on Earth, able to transform sunlight and atmospheric nitrogen directly to fixate carbon to form organic biochemical compounds. Their production of oxygen as a by-product led to a catastrophic pollution of the planet, the only survivors of which were the new lifeforms that had adapted to consume oxygen, and which are the origin of the diaspora of biological life as we now know it. The industrial Haber-Bosch process is an anthropogenic augmentation of a subsequent, weird biological symbiosis between legumes and remnants of that earlier bacteriosphere, an evolutionary contingency which allowed those nitrogen-hungry plants to migrate from abundant to relatively inhospitable environments. The advent of artificially-fixed nitrogen intensifies massively the dependency that developed between humans and these hardy deterritorialised plants whose symbiotic adaptation had allowed them to escape the contingencies of atmospheric nitrogen fixing. It locks in a new symbiosis between human culture, nitrogen, and the petroleum that fuels its artificial preparation to secure the yields demanded by an exploding population.

In line with the ethos of modern chemistry in broadening the range of chemistry's universality, the terrestrial landscape of nitrogen can be traced back yet further to its cosmic provenance: In the early universe, the 'ur-chemical' agency of gravitation (as discussed with Grant) locally breaks the homogeneity of spacetime and leads to a form of regional contraction (rather than spatial extension), creating local discontinuities and making possible the entropic conditions and chemical activities that form the universe as we know it. In the contracted regions, new morphogenetic transformations and condensations of matter begin to take place; stellar nucleosynthesis forms the furnaces in which heavy elements, including stable nitrogen isotopes, will be forged, thus brewing up, out of the undifferentiated continuum, the elements of a properly chemical, differentiated universe in which the terrestrial sphere will emerge.

Thus, just as the artist selects a single location to make a 'portrait' of the megasystem of anthropic terrestrial depredation, the unravelling of the nestedness of 'chemical valencies' within an organism or a culture gives rise to an epic chemophilosophical narrative in every case. It is in this way that a culinary materialism can open up a continuous yet twisted (topologically counterintuitive) depth beneath the surface or the ground: by bringing out the non-trivial relations between the cosmic continuum and its localized regions; by displaying relations between the earth and the regional horizons for thought that belong to it, and an unrestricted and unified conception of the universe.

The examination of the 'new earth' wrought by contemporary industrialised food production through its accessing of chemical powers continues in **FIELDCLUB**'s contribution. Offering an insight into the deranged machinations of laboratory capitalism, their investigation of the changing fortunes of the erstwhile waste product whey implicates humans, agriculturally-adapted animals and advanced chemical processes in an industrially-augmented culinary syntheses: the redistributive function previously fulfilled by the pig is usurped by a new chemically-enhanced human consumer, ready to fulfil the capitalist exigency to full exploitation of the earth.

In line with the general rise of the culinary, recent years have also seen a resurgence of interest in food in the contemporary art world – most emblematically, perhaps, in the work of Rirkrit Tiravanija. The 'relational' paradigm, with its emphasis on the convivial potency of non-object-based art practices, finds a natural home in the social setting of cooking and eating. This has also occasioned recent revisitations of the work of Gordon Matta-Clark, and the restaurant FOOD which he co-founded in New York in 1971 with **Carol Goodden**, who we interview in this volume. An undecidable, experimental project, FOOD engaged equally the multiple social, economic, convivial and material aspects of cookery and eating. But what was its relation to Matta-Clark's more well-known work, in particular his architectural interventions? In our interview with Goodden, we explore the extent to which the artist's interest in disrupting structure and breaking down closed spaces to produce new forms of communication, can be related to a more general concern with alchemical or culinary transformation, exemplified in early works such as his agar pieces and fried photographs. Here Matta-Clark's work is read as addressing the metabolism of the urban environment, where buildings and cities digest and are digested, as part of a universal culinary process: in the words of one of Matta-Clark's notes, reproduced alongside the interview, 'building materials as nature's food – build to feed the worms an organic eat-a-tecture'...

Recounting the origins of FOOD, Goodden depicts a city that invited an exploratory art practice taking as its 'point of departure' not only 'the whole of human relations and their social context' (Nicolas Bourriaud's aspiration for a relational aesthetics) but ways in which they are intricated with other (urban, architectural and alimentary) fabrics under this common culinary or alchemical principle. FOOD clearly staged the culinary, but Matta-Clark blended it with practices that make his city a very different territory, in truth, to the cities in which international contemporary art practice stages its convivial events in galleries (ironic exemplars of the 'independent and private spaces' Bourriaud hoped to escape). In exploring transformations beyond the preparation and consumption of food, FOOD pioneered conceptions alternative to the mere preparation and consumption of artworks. As Goodden suggests, for Matta-Clark FOOD was 'a grinding, regurgitating, consuming thing', a work whose ingredients and methods surpassed the restrictedly artistic or culinary.

The collective **AO&** offer another example of how the restricted practice of the culinary can provide a locus for the exploration of broader processes of production, communication and consumption. As we learn in our interview, AO&'s 'perverse' endeavour to fully inhabit the problem of food production operates through a deliberate and painstaking disclosure that makes possible an enhanced perception or phenomenology of the act of cookery. AO&'s meals do not stop at providing striking gastronomic experiences for diners, but operate as carefully-controlled experiments in the communicational potencies of the dinner table.

Crucially, AO&'s practice involves within the ambit of 'food preparation' the personal sourcing and assembly of all 'ingredients', including cooking materials, the preparation of the site, and the forging of connections with a network of producers. Hence they ask, 'Where is the edge of the pot?', preparing the way for a generalised culinarism that reaffirms the centrality of an expanded notion of architecture found in Matta-Clark's work.

AO&'s practice may, indeed, fulfil chef **John Cochran**'s demand for a 'flat cookery' that acknowledges its non-human participants. For Cochran, received practices of cooking – the haute cuisine chef's as much as the fast food burger-flipper's – 'distort ontology', creating an instrumental caricature of the objects they employ. Chefs, like philosophers, therefore, maintain uninterrogated 'ontological commitments' determined by their praxes. An 'object-oriented' approach to cookery, Cochran insists, would recognise that objects have powers that exceed our intentional interactions with them, and open itself up to this continuum of objectal powers.

In his examination of two 'revolutionary' contemporary food movements that claim to liberate themselves from normative models of cookery – Molecular Gastronomy and Slow Food – Cochran finds they fall short of this ideal: Molecular Gastronomy investigates the chemical composition of foods only to manufacture sensory fireworks, producing professional chefs and professional consumers alike; Slow Food lavishes its sentimental attentions on the social and cultural import of foods only to draw them into a global economy. In both cases supposed radicality supervenes upon an image of culinary thought that plays into the hands of an economically-driven professionalisation of the culinary, at the expense of amateur experimentation. Both are found wanting, missing the insight that 'food continues to translate you, and you continue to translate food, even after swallowing'.

Cochran's demand to open up the practice of cookery to this extended 'translation' raises the question of how one makes oneself 'a good meal' for the outside, detecting or inviting nonhuman contingencies into cookery. It is perhaps worth pointing out that this is not to be achieved through mere promiscuity or practices of 'openness' based on the aleatory or free expression. Paradoxically, it is AO&'s meticulously controlled culinary regime that, operating in varying settings, quietly affords an insight into what it is to cook and to eat.

In his contribution, **Manabrata Guha** expands upon the notion that sensitivity to the culinary powers of objects can offer egress from a spontaneous 'image of thought' into a wider continuum, an open system whose chemical, military, logical and modal dimensions he unfolds in his essay on 'The Chemistry of

Para-Tactical Engagements'. Guha reports on recent efforts at the weaponization of the massively potent *Bhut Jolokia* chili, finding the military project to harness its non-lethal power to incapacitate and disorient indicative of a strategic shift on the part of a state attempting to contend with a new threat, the 'enemy of all'. Outlining the futile nature of this employment of the *Bhut Jolokia* as a means to enhance an ill-adapted military model, Guha turns instead to the traditional culinary usage of the chili to reveal more fundamental lessons for the transformation of the schema of battlespace and the rise of a new vague and inherently synthetic adversary that renders political reason impotent, globally and locally.

For Guha, the insurrectionary subject is the synthetic distillate of the unbound continuum or 'the open', a singular field through which all chemical fusions and transformations pass. In the figure of the 'enemy of all', war is revealed to be far deeper than the political, the battlefield far broader than any number of discrete spaces that the state or contemporary military theory can envision. Since the synthetic horizon of the continuum is a trans-modal web that smoothly and gradationally blends the question of universal constituency (the open) with the question of tacticity (the opening of discrete fields), the battlefield is always conceived as a gradient that focally reflects the free expression of war and the unbound global battlespace within regional and discrete battlespaces strategically mapped out by the state according to the legacy of political thought. For this reason, for Guha, drawing on the mathematico-philosophical work of Fernando Zalamea, the battlefield of the insurrectionary subject is a regional approximation of the universal continuum or the open, whose exact boundaries are blurred, logic vague and topos purely synthetic. The insurrectionary subject of the global battlespace does not resist assimilation, but on the contrary, adapts a vague modal geometry so as to soften its particular edges and turn into a 'transplant' capable of inhabiting the state's discrete battlespace as an agent of catalysis, fusing the state's axiomatic structure with the non-axiomatic and unmasterable geometry of the global battlespace.

It is this chemical softening of exact characteristics and recapturing of the open (continuum) within the discrete horizon that Guha finds manifested in the traditional recipe for *Bhut Jolokia* chili pickle, whose vague identity (itself the outcome of the chemical fusion and synthesis of different global-local modalities) makes it a perfect supplement or side-dish that stealthily unpacks a wide range of culinary sensations within the unsuspected consumer, 'a catalysis-engineer that exposes particular and discrete entities to a sensorial continuum'.

Here, as in Gerrard's work, local chemical or culinary phenomena give us to understand how the open universal continuum reflects into (or experiences) itself through various complex transitions, modal fusions, global-local surgeries and transplantations whereby contingencies, possibilities and actualities are welded together or transplanted within one another: Hence, for Guha, as for Grant, the 'chemical paradigm' marks out a synthetic domain that precedes (without excluding) the chemistry proper of elements, reactions, and so forth.

Rick Dolphijn adopts another culinary approach to the contemporary 'state of emergency', analysing how the changing alimentary regime of the military anticipated and accelerated the rise of biopolitical governance through continual intervention. According to Dolphijn, the militarization of the world's diet and the territorialization implicit in dietary programs have resulted in the emergence of a terrestrial dietary/military continuum whose vague and synthetic elements are 'terroristsoldiers' (Guha's 'enemy of all'). The more the nourishment of the state and the soldier is drawn from the chemical earth, the more they become synthetic in nature, as interior and exterior become blurred; and the harder it becomes to distinguish them as discrete recognizable entities: this 'new continuum' becomes manifest in the terroristsoldier, who is figured in every individual and whose diet is the entire synthetic landscape of the earth. Dolphijn points to current olfactory research as a critical stage in this process since it involves topologically-'pointless' interventions similar to those involved in the 'self-cooking' of the *Bhut Jolokia* pickle (whose method itself echoes the Baconian experiments and Arabic poisons collected in the Appendix to this volume).

Dolphijn's and Guha's contributions expose the wider stakes of this intrusion of the chemical (continuum) into the political sphere and its discrete battlespaces: For both writers, the exploitation or weaponization of the culinary or the chemical by the state unwittingly exposes the latter's strategic political horizon to an open and contingent expanse that proves detrimental to the strategic and military integrity of the political reason manifested in the architecture of the battlespace or the biopolitical horizon. This highlights, above all, the veritable potency of the culinary: Since all chemical and culinary entities are already open to (and open us to) the rest of the chemical continuum through complex syntheses, interphased spaces and vague boundaries, and since the continuum is a non-axiomatic landscape, such entities throw the axiomatic structure of politico-strategic reason into incoherency – registered as an expression of a war already-there. As Dolphijn explains, this traumatic incursion, pioneered in the military sphere, has generalised consequences: here, as in the history of nitrogen, 'military intelligence speed[s] up modern life', bringing into play 'wholly other physicochemical, organic and anthropomorphic contours of the earth'.

According to Grant, the fundamental tenet of the 'chemical paradigm' demands we accept that no chemical process is identified and 'made available' without chemical intervention, 'regardless of whether that's done by chemists or by nature'. Dolphijn and Guha's texts show us that, indeed, it is always the continuum 'itself' that opens up the chemical horizon, allowing its local exploitation to 'take place', but that its unmasterable synthetic power always threatens to exceed and overwhelm this instrumentalisation.

In accord with this discovery that human cookery takes place within a prior (in Guha, even 'pre-ontological') complex that is already 'culinary', in his contribution **Richard Wrangham** deepens the notion that 'it is cooking that makes us human' – his thesis being that the advent of cookery is one of the major drivers behind the development of the human brain. In identifying the consumption of cooked food as an *evolutionary commitment* and thus a *dependency* – a 'decision' made for us and that determines our destiny – Wrangham reveals how the human culture of cooking belongs to nature's chemical and physiological horizon. For this reason, cookery must be seen in the wider context of a culinary continuum that includes the contingencies that formed the human as such, in advance of the cultural machinations that then become necessary to fulfil the energy acquisition requirements of an exploding population (Gerrard, FIELDCLUB). From a human point of view, cooking may be a cultural phenomenon; but from the point of view of nature, as Grant points out, this distinction cannot be made; we are cooked as well as cooks (*for years I thought I was cooking all this up, but nature was telling me what was on the menu ...*).

Perhaps the voluntarist, preferentialist nature of gastronomic consumerism may be disturbed by Wrangham's demonstration that we do not (as a species) have a choice about whether or not to cook; there is therefore indeed 'reason in the roasting of eggs', but it also follows that reason and its emergence is (as Nietzsche argued) of a piece with other (intestinal and colonic, for example) peculiarities that revolutionised the human metabolism and ultimately provided the conditions for both gastronomy and alloplastic chemistry. As Grant states, 'nature can be produced by thought precisely because thought cannot be produced outside of nature. But this alters what "thinking nature" means'. It also, we may add, alters, or even reverses, what a 'thinking of cookery' may mean – '*coquo, ergo cogito*'.

In 'Theorizing Cuisine from Medieval to Modern Times', **Vanina Leschziner and Andrew Dakin** chart the epistemic shifts implicated in the movement from a medicinal to a hedonic model of eating. Their contribution demonstrates how the norms of developed gastronomy harbour complexities occluded by their omnipresence and apparent transparency. Prevailing gastrological norms (in Leschziner and Dakin's example, the separation of sweet from non-sweet) exist at the intersection of many influences, where emergent sociological, institutional and epistemic conditions drive the exploration of alternative conceptual articulations of the 'phase-space' of possibilities provided by basic chemical, physiological, nutritional and adaptive factors. Thus, a culinary object such as sugar, with its basic chemical valence for human physiology, provides a kind of pivot around which, historically, differing conceptual structures are articulated – its 'endo-relational powers' (Cochran) exceeding the 'exo-relations' which any one of those ordering structures assigns it.

We should of course recall here FIELDCLUB's demonstration of how this plasticity with regard to what is 'edible' is augmented – to the point of reversibility (the transformation of whey from waste to ingredient) by the advent of ever more sophisticated commercial chemistry and constant innovation in markets. This plasticity opens the way to an experimental gastrological practice that could be related both to the exploratory 'flat cookery' recommended by Cochran and to the naturephilosophical experimentalism recommended by Grant: A cookery that addressed gastronomy in such a way would not rest with exhibitionist displays that inverted or recombined cultural norms (thus

Leschziner and Dakin's judgment on Molecular Gastronomy), but that would map out the landscape formed by zones of interference between 'objects' of different types (chemical, physiological, hedonic, institutional...) so as to discover new routes within it.

A curious demonstration of the possible scope of such a discipline comes in the form of the 'synaesthetic cooking' proposed by **Sean Day.** Day introduces us to the complexities of various types of synaesthetes' experience of flavour in relation to colour and language, demonstrating how the synaesthete's peculiar talents extend the culinary palette into a trans-sensory 'synthesaurus' that is at once polyphonic, polychromatic and trans-modal. Molecular Gastronomy has, famously, experimented with the integration of different senses (not only olfactory but visual and aural) into dishes. Day's synaesthesia prompts him to call for culinary practice to engage further, not only with the sciences that are able to analyse and synthesise its materials, but also more fully with neuroscientific research that could inform a more systematic approach to the interaction of different sensory components. This expanded form of multi-sensory cookery would transmodulate gustatory sensation; but, as Day observes, since synaesthesiae are often cemented in contingent individual associations, it could result also in culinary events – such as the 'phoneme-to-flavour' and 'flavour-to-colour' recipes he and James Wannerton propose – whose gastronomic appeal extends to only one person.

Following Day's recipe for 'Light Cyan', **Jeremy Millar**'s 'Black Cake', in an edition produced especially for this volume, is based on a recipe passed on by Emily Dickinson in an 1883 letter. We know, from contemporary accounts, of Dickinson's culinary skills; which are matched, of course, by the strong sense of the domestic in her poetry. But while the poetry can feel somewhat fragile, the same could not be said of her cake, which promises to be substantial indeed, and somewhat ill-suited to the taking of tea in an Amherst townhouse. Millar's rendering of the recipe allows us to think of the poetry differently, once more: beneath the fragile and hesitant procedures of the everyday and domestic, lurks the black earth [*al-chem*] of substantial transformation.

As we know from Claude Lévi-Strauss – a constant reference throughout this volume – we eat not just physical food, but also symbols. In his contribution to the volume, **Eduardo Viveiros de Castro** examines the extreme point at which the culinary meets the symbolic – cannibalism. An excerpt from his recent *Cannibal Metaphysics*,[1] the text reflects the reconsideration of anthropological perspectivism advocated in the book: Where anthropologists have sought to see 'from the native's point of view', Viveiros de Castro argues that their attempts to do so, paradoxically, have been limited by a very culturally-specific form of perspectivism. He proposes that within cannibalism, we can discover another remarkable example of a developed and socially-functional form of perspectivism: 'anthropophagy as anthropology'.

---

[1] *Métaphysiques Cannibales* (Paris: PUF, 2009).

Refusing an account of cannibalistic 'sacrifice' as divine expiation, Viveiros de Castro examines the ways in which the devouring of captives also amounts to an inhabiting of 'the enemy's point of view' on the self, with consumption of the other playing a central role in the social construction of identity. In this 'movement of reciprocal determination' by the enemy's point of view, Viveiros de Castro sees a 'mechanism for the ritual production of collective temporality': the '"interiority" of the social body is integrally constituted by the capture of the symbolic resources of the "exterior"'.

In recounting the determining events for his reconsideration of sacrifice, and his consequent proposal to expand the field by 'structuralising' the thinking of sacrifice as a thinking of forces rather than forms, Viveiros de Castro prepares for further developments in *Cannibal Metaphysics*, where he advocates Deleuzian Becoming as a more favourable conceptual resource than Lévi-Straussian sacrifice for asking 'what [it] is [...] that is devoured' when one human eats another. (Reading of Viveiros de Castro's contribution should be supplemented with Aparecida Vilaça's account (in the

Appendix) of the 'gustative pleasures' of cannibalism and 'ingestion [as] a fundamental classificatory operator [...] intrinsically bound to the notion of predation'.)

Eugene Thacker offers another perspective on cannibalism: Agreeing with Viveiros de Castro that the crucial point is whether the eaten body is a 'thing' or not – since in order to become food, corpses must be symbolically rendered into objects – Thacker relates the cannibalism theme to Anaxagoras' examination of the paradoxes of corporeal resurrection. How can the virtual integrity of the resurrectable material body be squared with the corpse's evident reprocessing through the anonymous continuity of material transformation (Matta-Clark's 'primeval cannibal chaos')? For if the body persists as resurrectable and thus as individual throughout its trituration and consumption by other organisms, throughout the 'culinary transformation of matter' through which 'the very materiality of the world is continually "cooked" (and eaten)', this would ultimately render every act of eating cannibalistic. Thacker finds Athenagoras' problem echoed in Bataille's notion of the discontinuous human's thwarted attempts to access 'divine' continuity – an access which, for Bataille, is approached in our relation both to food and to the corpse (here, as in Guha's argument, eating is associated with a threat to 'somatic integrity').

Thacker resists the temptation to expand a restricted notion of cooking to a generalised culinarism-as-anonymous-transformation, turning instead – via his reading of Bataille's theory of religion – to the notion of a 'desolate cookery' rooted in a negative concept of life and which (in an oblique departure from Cochran's credo) calls for an 'abject-oriented ontology'.

As Cochran points out, an expanded, acute sensitivity to the culinary situation is a necessity rather than an option for those medically constrained to intentionally regulate their metabolism. Constrained to exercise such 'mangé management' (to appropriate Matta-Clark's phrase), they have the same keen sense of the 'alchemy' involved in food preparation and digestion that Goodden indicates as having instigated Matta-Clark's inquiries. More extreme forms of discipline, and concomitantly acute levels of bodily awareness, are the subject of **Dorothée Legrand**'s contribution. The self-administered regimes of anorectics, she argues, sensitise us to the fact that eating is always a locus for the administration of the self. Introducing a move toward a deep (intra-subjective) phenomenology of consumption (in general) and eating disorders (in particular), her contribution emphasises how identity is produced through dietary discipline: diets are not simply eating programmes or schedules, but rather sets of procedures or recipes for the production of identity. As Legrand demonstrates, this relation between the diet and (self-)production is manifestly highlighted in anorexia, where ‘eating nothing’ translates into a series of complex semiotic, phenomenological and cognitive procedures for the subject with regard to the production of identity – ideally of an integrated identity that would be a miraculous ‘victory over digestion’ (Thacker).

Following from Thacker’s observation that ‘to eat is always to […] incorporat[e] oneself into the realm of anonymous […] processes’, and Guha’s insistence that the culinary continuum harbours a ‘threat to somatic integrity’, Legrand demonstrates that in the act of eating, the multidimensionality of bodily self-consciousness is foregrounded; we experience ourselves not only as subject but simultaneously as object and as anonymous material. As she meticulously sets out, this daily reminder that ‘each of us does nothing but carry a corpse about’ (thus Thacker’s epigraph, from Philo) can precipitate precarious existential experiments whose aim is to fully integrate the self through a process of ‘constitutive self-negation’ – a building of identity through an ‘infinitesimal’ process of subtracting self-as-object from self-as-subject. Such ‘intimate projects’ of ‘controlled transformation’ involve a culinary ascesis, but one that is based in a tortuously acute sense that eating involves the maintenance of the self qua constitutive tension between self-object and self-subject; or – in Bataille’s terms, as discussed by Thacker – between continuity and discontinuity.

As Legrand argues, the anorectic in a certain sense presents us with the truth of food, potently distilling the problem of 'the demonstration of one's existence' in the face of the 'narcissistic wound' inflicted by the knowledge that one must incorporate the anonymous in order to pursue the subject-self's ideal of integrity.

For Hegel, the externality of the food and its objective exactness provided the digesting subject with a dialectical opportunity to reclaim its identity on behalf of the subject.[2] But for Legrand, as for Guha and Thacker, food enforces a form of exteriority that cannot claim such exactness. The subject is vague and already-indistinguishable, and here it is food that becomes a 'mirror' in which one sees oneself 'from the enemy's point of view'. Legrand finally suggests that anorexia may emerge as symbolic process from the frustrated intersubjective demand that food be given, not as need-fulfilling object, but as a gift that feeds desire. Here, perhaps, is the fundamental function and ploy of gastronomy and its cultural overvaluation – the cultural exacerbation in discourse and culture of a necessary obfuscation of our relation to food, obscuring the anonymous, objectal dimension of subjectivity to which eating exposes us.

As in the martial alimentary regimes described by Dolphijn, for Legrand, consumption itself becomes a form of production (of identity) from the inside out, in '(non-)eating projects representative of one's subjecthood, and thereby constitutive of it'. Food produces the subject-as-object, and a 'new people for a new earth'. Legrand's understanding of consumption also recalls Ferenczi's account of assimilation as 'alien transplant', recalled by Guha in his 'exegesis' 'Serving the Open' (in the Appendix). For Ferenczi, eating and consumption create a polyvalent or nested chemical/culinary structure: Food is a foreign body that cannot be wholly identified in terms of its capacity for absorption (food simply as nutrient that is wholly reintegrated within the system) or for wastage (food as something which distinguishes the object from the subject, where all that is wasted is no longer part of the subject). While for Hegel eating ends with the overcoming, through digestion, of the foreign body that entered the sphere of the living being, and results in the dialectical reclamation of the individuality and being-for-self of the animal, Guha, Ferenczi and Legrand identify digestion as an interiorization of xeno-economical relations, wherein the subject – far from reclaiming its subjectivity – is chemically transformed by an object that resists full assimilation. In this sense, all food, no matter how well-cooked, is poisonous. Awareness of this xeno-economical space of extra-subjective chemistry, of which the subject is now seen to be a product, fully schizophrenizes the culinary cogito 'I am what I eat', just as the powers of its continuum vex the cookie-cutter battlespaces of the state. The dialectical valence of food for the subject, in its attempt to conclude its reality and self-relatedness, is challenged by this new model of assimilation in which food, the interiorized object, can no longer be distinguished as a discrete or exact body that can be either fully assimilated or conveniently ejected. Food, the agent of repletion, is instead vague (Guha) or ambivalent (Legrand), suggesting an economy of consumption in which the digesting subject cannot bring its relation to its food to any conclusive resolution. The identity that the consumer or the subject produces for itself through digestion is the result of devouring the object or food; but also the result of being internally devoured by it (Ferenczi) – as the terroristsoldier is consumed by the new chemical earth he is put to work on. In this sense, thinking in terms of a philosophy of nature, we might revisit the recapitulation thesis – characterised by Grant as a 'dynamics of the totality of nature' – as a process of 'eating the ancestors' (Ferenczi), a process in which digestion is never complete, in which traces – alien insiders – remain within, encrypted pathways into the labyrinth of the chemical continuum: this would be a 'chemophilosophy in the recapitulationist sense' (Grant) in which 'the discrete and the particular is always infiltrated by 'the open' (Guha).

---

[2] See G.W.F. Hegel, *Hegel's Philosophy of Nature*, ed. M.J. Petry (London: Allen and Unwin, 1970), vol. 3, 162-4.

Here we return to the theme of our previous volume; for it becomes clear that a culinary materialism opens up new vistas for geophilosophy. Nietzsche demanded that thought be 'true to the earth', extending the genealogical method so as to ground culture and thought in the stomach and on the terrain to which it is adapted (an aspiration satisfied in a different way by Wrangham's thesis). But Nietzschean genealogies only chart the history – after all, a restricted, localized history – of the surface; it will demand a further 'Copernican' effort to extirpate from philosophical thought the last vestiges of the human's spontaneous image of its dwelling place.

To be truly terrestrial, one must renounce the superficiality of the encrusted model of geophilosophy. Culinary materialism sets against *geophilosophy* as the philosophy of or for the earth – a thought that is 'true-to-the-earth' – *chemophilosophy* as a universal philosophy – a thought whose *topos* is an earth that is 'true-to-the-universe' (that is, an earth synthetically envisioned within the full spectrum of the open continuum). It is only this universalist earth that can serve as the veritable plane of thought upon which a chemophilosophy – a philosophy that opens up the earth to the continuum – is conceived. Chemophilosophy therefore marks the transition from geophilosophy to a philosophy whose earth belongs to a unified and open continuum whose regions are vague, gradationally open to various spectra that lie beyond the manifest surface and body of the planet. Within the continuous environment of the continuum, earth is then understood analytically *and* synthetically. If, for pre-Copernican alchemy, the earth was the foundation of all elements and the mother of all, containing within herself the seed of everything mineral, vegetable and animal, the chemical revolution – still in progress under the auspices of astrobiology and neurochemistry – subverted the centrality of earth to chemistry. By establishing that compounds can be synthesized across different domains, and subsequently by emphatically linking the particulate to the chemical, biological and psychological, the chemical revolution rediscovered the earth, not as mother of life or receptacle of celestial rays, but as a fuzzy and synthetic region of the chemical continuum, the outcome of a local 'recipe' that enjoys no synthetic or analytical privilege over the space beyond it. We can thus understand this volume on 'Culinary Materialism' not only in terms of a radicalisation of 'Geo/Philosophy' (**Collapse** VI) but also as a continuation of the legacy of the 'Copernican Imperative' (**Collapse** V) – that orbital subversion which also shatters the alchemical parental hegemony of *sol* and *luna* over the earth. The cardinal ingredients of this subversion can be read in Newton's recipe (in the Appendix): the homogenization of nature as one (continuum), combined with orbital humiliation (gravity), puts the earth into a new culinary relationship with itself: The gravity of the unanchored earth becomes at once a means to extend the chemical continuum of the earth and its compounds to the culinary landscape and the realm of taste and sensation, and a mortification of the earth by its own natural compounds and elements – earth literally cooked to death.

It is this decentralism that loosens the earth to the extent that the unheard-of syntheses discussed by Gerrard, FIELDCLUB, Dolphijn and Guha become possible; and as for the gastronomic products of the kitchen, the same kitchen that provided the conditions – historical (Grant) and pre-historical (Wrangham) – for scientific experiment and enquiry, their savour (as Grant anticipates) can and must now be understood in the very terms of the *activity* of the continuum revealed by that enquiry.

DAN MELLAMPHY AND NANDITA BISWAS MELLAMPHY develop such a post-geophilosophy, rethinking planetary 'ecology' as an 'ec[h]ology' wherein the thinker is 'translated back into nature' as its echo, and where the planet 'feasts upon itself'. Connecting the ourobouric or ovoid figure of this autophagy to the Nietzschean will-to-power, this ec[h]ology escries the *al-chem*, the black earth, as a *stomachos* or 'pit of blackness' – what Guha describes as the 'self-churning' continuum. It is also a vermicular thinking: as the worm translates all things back into black earth (see Darwin's recipe, in the Appendix), Nietzsche suggests that to be true to the earth is to be retranslated and to retranslate back into the 'terrible ground-text of *homo natura*' – a '*hideous gnosis*' that, once again, involves the poisonous contemplation of one's incorporation into/as anonymous process.

Mellamphy and Mellamphy's demonstration of the persistence and continued pertinence of alchemical thought sets the stage for our concluding contributions, which both advocate the compositional (perhaps even synaesthetic) kernel of philosophical thinking expressed and explored most resolutely in the hermetic tradition of alchemy, a tradition that bridged astronomy, medicine, gastronomy, mathematics, optics and art, and was conceived in the philosophical and proto-scientific furnace of such figures as Jabir ibn Hayyan, Arnaldus de Villa Nova, Ramon Llull and Nicole Oresme.

Although in the transition from proto-science to modern science and with the birth of modern chemistry, the alchemical ladder of nature (*scala naturae*) was effectively toppled and the hermetic tradition dislodged from the centre of philosophical inquiry to the margins, philosophy's compositional kernel and its culinary ability to globally combine analytical loci of thought and coalesce incommensurable ingredients so as to mediate the universal experience of a bottomless nature was never fully abandoned. The compositional ambition of philosophy and its engagement with synthetic environments, mixtures, synoptic perspectives, spectra of knowledge and modal transits (contingency, potentiality, possibility, necessity ...) across the continuum of nature, has been reappropriated and extended by Novalis, Schelling, Peirce, and most recently by Fernando Zalamea and Gabriel Catren. In the alchemical tradition, the synthetic and compositional valence of elements or local fibres was tested by a process known as *tinging*, whereby metals were introduced to fire in order to reveal their transmutational hierarchy (tints or tones) and synthetic powers on the basis of a projection of the spirit or redness of fire or the Sun. For these latter traditions, philosophy's synoptic and compositional kernel systematically unfolds the synthetic threshold and compositional valence of all local fields of thought and the universe according to how the omnipresent and open universal continuum flows through them and comes into 'focus'. Therefore, philosophy becomes an 'alchemical paradigm' in itself that 'tinctures all thought and nature',[3] and in doing so, deepens the reflexive and trans-modal self-experience of the open universal continuum, bottomless nature, or 'b[l]ackground' (Mellamphy and Mellamphy).

In line with his study of an open or non-Cantorian continuum built on Peirce's late logical thought, involving topics such as the continuum, the topological basis of logical distribution, modal geometry and synthetic thought, **Fernando Zalamea** has in recent years pursued a mathematico-philosophical project committed to a *de-rigidification* of thought. For Zalamea this de-rigidification cannot be properly undertaken without having a systematic mathematical account of the unbound continuum. Absent any observation of the mathematical universe and the labyrinth of the continuum, philosophy's ontological and epistemological claims tend to lean toward one aspect or regional partition of the continuum, and accordingly rigidify the continuum in one way or another. Philosophy in this way becomes a myopic discipline that sways either toward realism or idealism, synthesis or analysis, integration or difference, thus becoming incapable of radically thinking compositions, mixtures, contaminations, decompositions, transitions of nature to culture, cultural fusions and transits – in short, the full chemical spectrum or culinary constitution of the universe. In other words, without maps and compasses to explore and survey the landscape of the continuum, philosophy ultimately fails to develop a synoptic view constituted of both analysis and synthesis[4] – it falls prey to the same kinds of distortions that Cochran describes as being at work in Molecular Gastronomy, that recent return to the ancient bond between science and the culinary whose overanalytical jellies tend to disappoint; or worse, like fusion cuisine, it succeeds only in ineffectually aping the trans-regionality that is its vocation. As is the case with 'rigidified' philosophies, failure to achieve a deep and synoptic scope consigns such efforts to cultural myopia: dabbling in or 'applying' science or cultural difference, they remain unable to deepen their cultural and gastronomic aspects in relation to a universalist chemical horizon capable of giving rise to culture or cultural experiment.

[4] For a view, both detailed and panoramic, of cultural mixtures and compositions in relation to contemporary mathematics and its transmodernist implications, see F. Zalamea, *Ariadne and Penelope: Webs and Mixtures in Contemporary World* (Oviedo: Ediciones Nobel, 2004).

The recipes Zalamea contributes to our volume (to be taken with a pinch of salt) examine, firstly, the failed recipe for thought that aims only at an astringent clarity; and secondly, the *villageoise* constitution of a transmodernism fit to counter such *petit cuisines philosophiques*.

In Zalamea's recipe for a transmodern thought, so in **Gabriel Catren**'s 'alchimirical' instructions for baking a philosopher's stone. In instructing us in the contemporary procedure, Catren presents philosophy in terms of the alchemical *tinctura universalis* discussed above. The result is as much a polychromatic and polyphonic – that is, broadly universal and non-trivial – unfolding of the real as it is a synaesthetic, even psychedelic, experience of the culinary. In an epistemic exacerbation of the deregulation of the sensory faculties advocated by Day, Catren proposes that the transmodern vocation for philosophy consists in a 'true-to-the-universe' regime counteracting the 'spectral decomposition of experience' prismatically produced by various modes of thought; his black earth is a concretion effected by the 'polychromatic mediators' of a 'philosophical synthesizer'.

It is evident that the various alchemical operations, absorbed into the mundane activity of cookery, can then become metaphorical tools for a generalized culinarism; yet to satisfy oneself with this metaphorical transport is to fail to realise the more fundamental pertinence the latter could achieve. In Catren's alchimirical cauldron as in Zalamea's transmodern tatin, the procedures indicated to operationalise and concretise regional echoes of the universal culinary spectrum are stripped of all metaphorical reference to the restricted practice of cookery. Instead they invoke the abstract operations that contemporary mathematics uses to synthesise its complex variety of confections and recipes (Freyd's allegories, sheaves, fiber bundles, etc.) from the elemental materials of the continuum. This points the way toward a refinement of a transcendental 'chemical paradigm', a culinary materialism that not only escapes the 'reductionism [of the] culinary [...] analogous to anthropism' (Thacker), but entirely renounces dependence on any empirical model.

This volume, together with the Appendix of recipes, should be taken as a preliminary exploratory exercise

– to be continued by the reader – in the mathematico-philosophical vista of culinarism revealed and brought into focus here. A prospect that certainly answers to the original recipe for this volume (from which, however, the editors have not resisted straying); but which, thanks to the transmodern spirit of our contributors, surpasses it, suggesting not only a culinary thematics for philosophy outside bourgeois gastroculture, and a variety of new perspectives on cookery itself, but a true 'proliferation of *possibilia*' (Guha); a taster menu for the unheard-of philosophical feasts, bouillabaises and concoctions heralded by a chemophilosophy, alchimery, or culinary materialism.

The Chemical Paradigm

Interview with Iain Hamilton Grant

Iain Hamilton Grant, one of the four philosophers who spearheaded 'Speculative Realism',[1] *is distinguished by being the sole proponent among them of a renewed philosophy of nature. He has argued convincingly*[2] *for the erroneousness of the modern and contemporary dismissal of the* Naturphilosophen *who sought to think the absolute according to the generative power of nature, integrating knowledge of the contemporary deliverances of the sciences into their speculative systems.*

Collapse spoke to Grant about this indistinction between philosophy and science, about the particular importance of chemistry as a new model for the thinking of nature, and about the pertinence of the culinary for a contemporary synthetic philosophy.

---

[1] See Appendix to **Collapse** III.

[2] See I. H. Grant, *Philosophies of Nature after Schelling*, 2nd edition (London: Continuum, 2008), 19-21.

Collapse: In the context of this volume on *Culinary Materialism* – cookery as a possible model for or provocation to philosophical thought, as an activity as unique to humans as philosophical thought, we would like to delve into the specificity of chemistry, and to understand why you have proposed it in various places in your work as a particularly important model for thinking. In particular you re-examine its importance in the age of 'natural philosophy', when the sciences had not yet attained the success necessary for them to extract themselves from philosophy, and yet were making momentous, and demonstrable, discoveries about nature.

Firstly, what constitutes the specificity of chemistry as a science - and how does this distinguish it from physics as a model for thought?

Iain Hamilton Grant: There are two things that serve – particularly in the era you mentioned, but also I think beyond that – as what we could call a 'chemical paradigm' for thinking. The first is that it gives an additional dimension to the empirical domain, a dimension that the other natural sciences – bar medicine – didn't have. Medicine simply involves working out animal economy – circulation, patterns of blood lymph and so forth, and so involved messing around in the interiors of bodies; chemistry involved messing around in the interiors of bodies that had no such organic complexity. It involved a messy experimentation, a grubbing around in the earth - whence the word *alchemia* derives (according to some): the 'dark earth' [*keme*] of Egypt becomes *al-chemia*, becomes *alchemy* and then *chemistry*.

So that's one thing about chemistry: it gives an additional visceral dimension to the empirical, which at one and the same time enables chemistry as a practice to have a specificity that separates it from the other natural sciences, and gives an additional character to experiment. And this is the other, more conceptual side of the question: in all the other natural sciences, certainly around the eighteenth century, there is *nothing* that compares with the *model of knowledge* that chemists were proposing: analysis is one part of the equation, but one understands nothing until synthesis has taken place. In other words, it's not just about understanding the 'nature of nature', not just about metaphysics – its about *recreating* nature. That synthetic ambition is unique to chemistry – it's about production as well as analysis. And the idea that knowledge is only complete once production has taken place, is something that informs Kant's immediate inheritance from chemistry. He mentions this in terms of experiments with calx, especially in relation to Georg Ernst Stahl, a noted vitalist of the era, but also someone who had insisted that to analyse calx was one thing, to resynthesise it was precisely the goal of chemical knowledge.

So it's those two dimensions – the additional elements of the empirical and the additional elements of the conceptual and thus of the experimental. The empirical side is to do with messing around in bodies with internal complexities which are both *irreducible* and *non-organised* (in organic sense). And the other side is that, as a model for epistemology, there is nothing that substitutes for chemistry's ambition to synthesise its products as well as analyse them.

C: Regarding this 'grubbing around in the earth', Dumas says: 'the science of chemistry was born at the potter's wheel, in the glazier's workshop, the blacksmith's forge and the perfumer's salon.' We would, of course, like to add that all of these practices were most likely born in the kitchen. For instance it has been suggested that chemistry was 'invented' with the burning of malachite, which would release molten metals that would run out from under the cooking pot ... Which is to say that chemistry has this relation to everyday praxis. Would be right to say that at the root of the still-reigning hegemony of physics as a model for the philosophical thinking of nature is the fact that the Greeks categorised chemistry under manual work – under *logistika* – separating it from theoretical speculations on the nature of things? So that, although chemistry may be the oldest science, its lowly origins preclude it from being recognised as the most fundamental, and this conflict continues to resonate through our contemporary epistemologies?

IHG: The normal stratification of the sciences in terms of fundamentality has physics at the bottom, and chemistry as the intermediary between it and biology; and thereafter everything else is merely subdepartments of those. Although there's a really fascinating sense in which no-one really knows where chemistry lies on the spectrum of the sciences. But as you say, there is an immanence of chemistry to life not merely understood in the abstract, but understood in terms of the most concrete practices: one could create a glorious spectrum of chemical activities, from breathing, to the osmotic porosity of our skin in respect to liquids with which we come into contact; but on the other hand, this quite abstruse range of human activities involved in the production of things; and again it's the element of production that distinguishes all of these.

If you look at the alleged fundamentality of the physical sciences, this is still regarded as a Platonic dream. One finds it in even in the criticism of naturalism as Platonism by authors such as John McDowell recently: physics is still considered not just as the domain of armchair theorists but as this linear speculative model intended to serve as the fundament for everything else, if only we can pull the theory back together, if only we can find the Grand Unifying Theory ...

C: The physicist-platonist would, presumably, argue that in attributing any fundamental role to chemistry, one would confuse ontological with historical or anthropological priority; in which case the question then becomes, what *do* we include in ontology: if ontology includes the structural principles of the synthesis of matter, then chemistry is ontological, since the greatest achievement of modern chemistry lies not in breaking down the elements, but, as you say, in identifying invariants in the way they can be *assembled* – isomerisation, the fact that different compounds can be made of the same elements yielding different properties.

IHG: The elements of ontology are produced, naturalising historicism while denaturing critique, so to speak. This is a favoured response of the late eighteenth century philosophers of nature (Ritter, Steffens), and retains its pertinence so long as the question can still be put. What remains, however, is priority.

C: Historically, how do thinkers in the period you are particularly interested in work out that priority?

IHG: If one rehearses the order of priority on the basis, not of ontology or in terms of philosophical anthropology – and a brief parenthesis on that: there is a fascinating extent to which you could deliver chemistry as the furthest reaches of a philosophical anthropology *à la* Heidegger; you could really develop a question of Being as posed by elements, in so far as these are immediately involved in the exchanges that constitute us physically. Another way perhaps of looking at the animal/world distinction, where a further stratum might be interposed between them in order to generate both animal and world, and to sustain them. In this, the idea of animal economy might again be important. At the outer limits of philosophical anthropology, you could do something like that with chemistry which would be fascinating. Here there are the beginnings of a reversal that is quite interesting and which neither relies on *Dasein* nor on somaticism; this reversal is Schelling's account of *what is involved in sensation*, which is what he calls a 'chemical dynamics'[3]: He sees the fundamental elements of sensation as being what happens when you have exchanges, when there are possibilities of fundamentally chemical exchange; although physics may be viewed as fundamental in terms of providing light, in terms of the sun, astrophysics and so forth, there is nevertheless a process of exchange that constitutes the very Sun.

---

[3] 'Chemistry is nothing else but sensory dynamics', *Ideas for a Philosophy of Nature*, SW II, 323-4 tr. E. E. Harris and P. Heath (Cambridge: Cambridge University Press, 1988), 257.

So, the idea of ontological priority being attached to physics rather than chemistry rests on a version of linear production that chemistry confutes, and this is why we could comfortably talk about, as it were, the genesis of all things, in chemical terms, or at least in terms that directly reference chemistry.

So the other side of that is, I think, that there is this fascinating question that arises in the context of the thinking of the philosophy of nature at the end of the eighteenth and the beginning of the nineteenth century: this question is basically 'what is nature' – one of the most fundamental questions, the Greek question obviously, the question of the pre-socratics, also the question of Aristotle, and Plato's question. The answer they all give is that nature, *phusis*, is generation first and foremost – it's not such and such an entity, object, structure or whatever, it's *generation*. So, for example, even Plato, in the *Timaeus*, when he talks about nature, talks about the *generation* of things. There are structural elements in it – he does talk about fundamental ontological elements in the constitution of things presented as the 'world soul', although it is important to note that for Plato 'soul' is *arche kineseos*, the source of motion, rather than *substance* – but they are elements of the *constitution* of things, and the science of the constitution of things is, in the terms in which we are discussing, a chemical science – it involves exchanges, it involves reciprocity.

So, the question 'what is nature', 'what is *phusis*', is answered by the Greeks as '*genesis*'; and for the eighteenth century *Naturphilosophen*, that also becomes the dominant paradigm. And what's interesting is the relationship between the changes that are taking place in the nomenclature for chemical elements post-Lavoisier – changes that, if you like, lend those elements the appearance of metaphysical simples – and the role chemistry plays in changing the thinking of the scientists and philosophers of the period concerning how to pose this question of nature, and what kinds of terms it would be satisfactory to answer that question in. The interest there is centred around this basic question of *what is a chemical element* on one hand, and *what is a chemical process* on the other. The set of nomenclatures that Lavoisier invented were intended to be simples that one could always analyse out of any process, through chemical intervention. But it's a mistake to regard these processes as being 'available' *without* chemical intervention, without processes of analysis and synthesis. Because the idea is, in effect, that the elements are constants in the process of breaking things down and putting them back together again, regardless of whether that's done by us – by chemists, scientists – or whether it's done by nature. So it is the entire process of analysis and synthesis that is the object of chemistry, rather than the element. And it's that reciprocal relation between analysis and synthesis that is key in rethinking nature, *phusis*, generation, in terms of chemistry rather than in terms of structural invariance or whatever.

C: Could we see the *Naturphilosophen*, and this dawn of a new productivist, synthetic model of knowledge, as transitional between the 'first' (rationalist) scientific revolution, and the massive industrialisation of chemical processes in the nineteenth century? If so, then what is their relation, and that of chemistry, to the romanticism that is contemporaneous with the latter?

IHG: Absolutely. And even in England, you could consider Humphry Davy's experiments on leather tanning, and the miner's lamp, all of these renowned practical solutions to practical problems. But the problem of engagement is being posed here – the question of what is happening when there is any engagement whatsoever in nature. Now 'romanticism' is a misnomer in two crucial respects: as regards romantic natural science, the immediate scientific paradigm that comes to mind is biology. The replacement of mechanics with some form of organics is the story that is told, and it's wholly misleading. If you look at the biologists, they're not reducibly biologists, indeed the word 'biology' only becomes current only in about 1802, considerably later than a lot of this so-called 'romantic science' was happening. Consider for example someone like Kielmeyer (who taught Cuvier – he was not a nobody in the context of the natural sciences!) In 1793, he wrote a discourse on the proportions of forces, which is ostensibly – or is recounted in books of the history of science as – the first proposal of the Mekkel-Serres law, the recapitulation thesis, that ontology recapitulates phylogeny. However, what he's actually after is what has been characterised by Timothy Lenoir in terms of a Laplacian dynamics of the totality of nature – from geogeny through to noogeny, from the production of planets through to the production of thought.

This question about recapitulation is a question about the fundamentality of the cell. In microbiology the question of levels is quite simply: what's basic and what isn't? If the cell isn't basic – and it isn't, phylogenetically (that is, in the genesis of phylla at all), it's a late acquisition, and is highly conditional (there are all sorts of conditions required) – then what is the unit of analysis sufficient to reveal any relation between phylogenesis and ontogenesis? And it's quite clear that this question is evident in Kielmeyer: he was asked by Windischmann: Is it possible that creatures recapitulate not just from the plant to lower animal to higher animal, in the development of species; but actually recapitulate the entirety of earth history? In other words, how many processes have to be gone through in order that later creatures emerge rather than earlier?

And it strikes me that once you admit that prospect, you very quickly lose any particular somatic referent to pin the basics to. That's chemophilosophy in the recapitulationist sense – the bottom drops out of the picture, the element drops out of the picture, and in place of that you have a non-determinable series of recapitulative cycles.

So, once again, it's a mistake to see the romantic notion of science in terms of biology. This is what defines romanticism, I think: it's not this or that aspect of nature, but nature as such and as a whole. The reason no-one's a Cartesian is the total supplanting of this or that part of nature with the idea of nature as a whole: *nothing* that happens is *not* a part of nature, by definition – otherwise it wouldn't happen. And this includes the most ridiculous of adjuncts, what Aristotle would calls 'accidents' and therefore non-essential components. It's that elimination of the distinction between necessary and accidental.

C: During the period we are discussing, we find a *confluence* between chemistry – before it really had a word for itself – and philosophy. It wasn't just philosophy *reflecting* on chemistry.

IHG: No; in fact the idea of separating the two was as alien to the *Naturphilosophen* as it was to those who overtly opposed them: who opposed them fundamentally on grounds that cannot be reduced to either the philosophical or the scientific. I don't just mean that in a modern sense, I mean simply that the model of knowledge across the community of investigators of the problem of nature does not rely on one set of tools rather than another. And one can identify two reasons why that would be the case, neither historical, both conceptual: One is that, to see the production of concepts as being in any way separate from the production of other natural phenomena is bizarre. No-one's a Cartesian by the end of the eighteenth century; at best what you have is attempts to generate the phenomena of life by artificial means – hence the importance of Galvani's electrical experiments with the voltaic pile, for both philosophers and scientists. There was a German term, *Naturforscher*, which we translate as 'natural scientist' , but 'student of nature' is the direct translation, and that's probably the best way to refer to people working either side of the conceptual schism, as it were But as I say, there's no way of separating them. The reason, firstly, is that no-one regarded thought as being alien from the rest of the processes of production that take place in nature. But secondly, the idea that conceptual activity constitutes or is limited to a reflection upon pre-established entities, simply doesn't cash out in terms of practice. There's a terrible tendency in the history of science to rewrite periods that we don't agree with in terms of what we do. So if you look at some of the essays in the mid-twentieth-century, up to about 1975, on the speculative philosophy of nature, on the one hand they are full of venom about the work of the earlier period; on the other hand they want to say that anything that might have been of value in it, was in fact arrived at by different means. But this is actually a staggering admission: if there is more than one means to arrive at a given product, whether this be urea or concepts, then why resist the opportunity to pursue that? And the business of the study of nature could not: If there is nothing that is *not* a part of nature, then any starting point, anywhere, of any nature whatsoever, is going to arrive, if not at the same conclusions, then at parallel conclusions, or at conclusions that stand in certain structural relations to other conclusions, to other investigations ... Once again, the model is one of production rather than just understanding, and so we're not dealing with epistemology, we're dealing with fundamental meta-physics, which rests *in* nature *qua* production, rather than simply being *about* it.

C: The birth of chemistry in culinary praxes that we have postulated, is extended by later developments of chemistry which were to a large extent industrially-driven; and implications of the 'synthetic interventions' of chemistry continue to unfold now in the biochemical and biomedical sciences. A key moment was in 1838 when Wohler made urea in the laboratory, and the way this is presented make it clear that this is an early example of the sort of experiments that are the stuff of indignant media outcry: Wohler exclaims, 'I can make genuine urea without using the kidneys of man or beast!' – an incredible revelation, and one that should perhaps be numbered amongst Freud's 'great humiliations' of man ...

IHG: Yes, and it is the model of *production* rather than mere *understanding* that is the basis of the 'chemical humiliation'. This recalls OncoMouse™, about which Donna Haraway made such a delirious noise[4] ... and also the synthesis of skin – all repetitions, precisely, of the production of urea – piece of piss!

C: Which contradicts the retrospective illusion that earlier science was somehow *purer*, was merely concerned with analysis and understanding; and that it is only in late modernity that we come to the point when we are pushing it too far, and creating industrial monsters ... in fact it's always been about tinkering with the creation.

IHG: Yes, hence the apologias with which works of natural science – and of philosophy, it should be said – open; hence the discounted questions; hence

---

[4] D. J. Haraway, *Modest_Witness@Second_Millenium. FemaleMan©_Meets_OncoMouse*™ (New York: Routledge, 1997).

Newton's otherwise unforgivable dualisms: they have at least an historical, sociological explanation. But I think, in addition, the model of science as being about understanding, about analysis, is regrettably impoverished.

And the same question, I think, can be posed to philosophy: to what extent is philosophy just sitting on the sidelines, wondering how we can understand X, rather than entering into a process of investigation, the investigation of thinking nature but not thinking nature reductively: nature can be produced by thought precisely because thought cannot be produced outside of nature. But this alters what 'thinking nature' means.

It's about experiment not simply in terms of results, but in terms of design, in terms of what sorts of interventions provide what sorts of reaction – Bacon understood that, but what do we take from Bacon? Merely the rejection of Aristotle.

C: The notion that there is an 'overcoming' of aristotelianism – an overcoming of qualitativism – in the quantitative approach to chemistry?

IHG: Exactly that notion, but it rests, of course, on unacknowledged occlusions: certainly Aristotle's physics and zoology and so forth are inherently qualitative in ways that acknowledge it as nothing other than a description of nature. However Aristotle's account of the natural world is itself parasitic on the rejection of various structural models, various abstract models that one finds in Plato for example. So, not simply the example of mathematics, but the idea that there aren't abstract models that coexist alongside Aristotelianism, and indeed that are made out of Aristotelianism after the neoplatonists' synthesis: the compromise between Aristotelian physics and Platonic physics is made precisely in terms of abstract models of production and cycling and exchange of 'phenomena amongst themselves' – phenomena on their own, so *things* rather than phenomena, really. All in terms of a dynamics. So the idea that there would be a period that we could call 'Baconian' that begins to supplant qualitative description by means of abstract modelling, I don't think is an accurate portrait of the history. However, given that something does happen, and that Bacon is doubtless a substantial contributor to that, we have to ask what it is to which they're responding. And some of the continuities between Cartesianism and the medieval precursors, late Aristotelianisms – to what extent are they purely qualitative, to what extent do they become not merely quantitative but highly abstract. So the grammar, the logical grammar of objects, ceases to be the syllogism, substance and its accidents, that Aristotle presents.

C: Let's now try to test this suggestion that physics and chemistry might represent two different paradigms or models for philosophy: The model of physics envisions a philosophy that deals with analysis into ultimate entities, whereas a 'chemical paradigm' would include a certain experimental component and a 'synthetic ambition' for thought. Can we challenge this simple dualism by exploring the ways in which physics, in fact, is continuous with chemistry (is there, in fact, any specific point at which we can disjoin them?); doesn't physics itself incude its own chemical way of thinking?

Consider the 'cosmic cooking processes' that generate the universe as differentiated, before there is 'chemistry proper'): If gravitation precedes heat and elements (the general requirements of material chemistry and cooking processes), then it deepens the chemical horizon, from that of processes and matter to that of the continuum itself: Gravitation creates a new form of modality in the universe, outside the qualitatively homogeneous continuum. Whereas we usually associate physics with the qualitative homogeneity of spacetime, we should note that gravity serves as the universal thermodynamic motor of complexification, and synthesises the 'ingredients' that generate regional contraction or intensification and thus local syntheses. So gravity could be seen as the force which creates a bi-modal web: universal-local, generic-particular; revealing the gradational spectrum of the continuum wherein transitions and transports along complex modalities unfold as modes of cohesion, liquefaction, production and synthesis ... at which point the objects of chemistry 'proper' emerge. In this case, the 'chemical paradigm' would not belong to chemistry, since there couldn't be a chemistry unless physics was already a synthetic rather than a nomological science.

IHG: If chemistry opens up the paradigm of the synthetic as a way not simply of doing 'philosophy of science' but of doing philosophy of nature, then yes; clearly there's a chemical way of thinking about physics.

Do we understand chemistry and physics as representing different extensive domains, or as having different extensive quanta with regard to their field of objects – being ontologically more or less comprehensive? If that were so, it would suggest that chemistry is in fact related to a circumscribable domain of nature. What then would be the status of thinking synthetically about physics? If it remains analogical, then we're back at the situation of being able to talk about nature only analogically, in its fundaments, exactly as Kant could; we're no further along than Kant's biologism, even though we're calling it chemistry. It cannot be merely analogical. Therefore it cannot be the case that this synthetic paradigm that belongs to chemistry can be limited to the chemical domain: it must be actually instantiated in gravity. And if this is the case, then are we merely talking about a chemical paradigm for thought, or are we talking about a chemical process? You see the same thing with [cosmologist] Lee Smolin talking about whether the laws of physics in the early universe are the same as the laws of physics in the late or middle-aged universe. If they are the same, regardless of time, then what precisely is the status of evolution in terms of nature? Is it just the exhaustion of local possibilities with respect to inherently contingent particular spatio-temporal creatures or entities? Or does it apply to nature as a whole? If to nature as a whole, then it cannot be the case that the laws of nature are the same in the early and the late universe. So there you would have a biologism that would extend to the totality of nature. I think it would be a question therefore of by what means we could conceivably manage the relationships between local and universal with respect to chemistry and physics: Is there a conceptual apparatus that could do that without in fact creating the correlationist problem; without creating, as it were, a reality that sits outside of what can only be referred to analogically by dint of access by, let's say, a restricted creature, or a synopsis that fails with respect to the totality?

The other way of thinking about it is to talk about particular processes, particular expressions that manage or do not manage to achieve a certain degree of extensity with respect to the all. That's how I prefer to think of it. I talk about the 'extensity test' in *Philosophies of Nature After Schelling*. I thought about this as a practical programme for doing the history of philosophy. You could take various philosophical systems and ask, how far do they reach, what do they exclude; so you measure the success of ontology by virtue of what it excludes. And anything that excludes is manifestly wrong – a basic Schellengian principle – and invites a problematic of either eliminativism or productivism on the one hand, or of hyperinflationism with respect to a presumably limited ontology on the other. So the test of extensity merely says, where's the biggest metaphysics ...

Stengers and Bensaude-Vincent, in their work on the history of chemistry,[5] do write about chemistry as being the science that invents its own universal, and they invoke Schellingian aid in doing so. And there is something interesting about the 'invented universal' – it's doing the same undercutting, but with respect to constructivism, any constructivist solution of the sort that you find in various neokantianisms, but also I think in various strands of contemporary philosophy, many of which make claims beyond their fundamentally Fichtean metaphysics.

---

[5] Bensaude-Vincent writes: 'Chemistry creates its own object, manufactures its Universal'. 'Lavoisier: Eine wissenschaftliche Revolution', in Michel Serres (Ed.) *Elemente eine Geschichte der Wissenschaften* (Frankfurt am Main: Suhrkamp, 1994). 671. See also B. Bensaude-Vincent and Stengers, *A History of Chemistry A History of Chemistry*, trans. D. van Dam (Cambridge MA: Harvard University Press, 1996).

C: What are the implications of *extinction* for a chemical paradigm of nature and chemophilosophy? If proton decay really occurs, then this means the end of chemistry proper. How can chemophilosophy get past chemistry proper, and the regime of matter, without essentially dismissing materialism?

IHG: If 'materialism' is reducibly and exclusively about bodies, then we do indeed have a chemical philosophy, but a chemical philosophy of the sort that Lavoisier dreamt of, and indeed beyond the sort that he dreamt of: a nomenclature that represents the primary bodies of the universe, which are immutable, etc. So, it's only in such an instance that proton decay would result in a challenge to chemophilosophy. Whereas if matter is more than body, then it follows that this isn't the same type of problem at all. If it makes sense to talk about materialism in the context of anything other than body, then it's a very interesting question. Plato, for example, does not talk about 'Idealists' in *Statesman* (273b5) – the word is *asomatoides* – the incorporealists. And the Stoics obviously picked this up. So the really big question is what comes first, powers or bodies; must powers inhere in bodies, or are bodies consequences of powers? If powers inhere in bodies, then powers do not explain the origins of bodies; and therefore we have a fundamental dualism between powers and bodies. If bodies are the products of powers, then not only do we heal the dualism, but also the decay of the body then tells us nothing about the nature of matter.

C: Thus we arrive at field theory, which you discuss at length in *Philosophies of Nature After Schelling*.

IHG: And this relates directly to the history of chemistry – electrochemistry, electromagnetism, Faraday ... the issues of the identifiability of processes stem not from bodies, but from fields and the interactions they have as their consequences: particular realisations and instantiations in particular bodies. The idea is that if being incorporates more than just body – and if it doesn't, then the origin of bodies is incomprehensible – if it does, therefore, incorporate body *and* powers, powers sufficient to make bodies, then we have this dualism: if being therefore incorporates anything more than bodies and powers in a dualistic relation, it must be powers first, and bodies later. And if that's the case, then the ontological bases are not this or that body, but powers that coalesce and accrete in them.

C: We could bring this back to the question of gravity's cauldron again ...

IHG: Yes, and Plato: *Sophist* 247e – 'I hold it as a mark of being that it consists of power'.

C: Does the pursuit of a philosophy of nature ameliorate the anxieties attendant upon scientific eliminativism, leading to an inclusivism that satisfies the intellectual instinct for the 'universal' in a different way? So that rather than scientific thought being (as in Ray Brassier's *Nihil Unbound*) a trauma that dispossesses us of everything we 'knew', it becomes a means to engage in a more 'Ferenczian' examination of traumata as cosmic elements that are already indwelling, bored through us, that compose us?

IHG: I think the anxiety of loss, the anxiety of disenchantment in certain post-Sellarsian eliminativists, and certain strategies for *re*-enchantment, have this in common: that if the sciences are able to achieve this elimination, it rests on the assumption that ontology is subject not only to scientific determination, but to scientific *revision – at the level of ontology*. In other words, that there are no entities left over to which folk psychology may have referred, or to which animists may have referred. In other words, we no longer even have to ask the question of what is it that animated these rocks in order to make such and such an event to occur – because that rests on a mere misunderstanding. However, does this mean that at any level we have achieved the elimination of animism? One strategy in this (and I take this to be the one that rests on the interminable reciprocity of nature and culture) is the Adorno/Horkheimer one, which is to say, as the response to positivism, that this brave new world is as animistic as can be imagined: The archons continue to haunt the surface of the earth even as they're ensconced around ocean-floor volcanic vents. But on the other hand, what is it that reduces the local conditions at every level for every phenomenon whatsoever to 'mere' conditions as opposed to entities and processes that in fact take place? So in other words, what's the status of the tunnelling or boring? There are several kinds of real tunnelling or boring. Some of them result in real trauma for animals able to talk about it; some result in areas of Cornish fenland that are unable to support life; some of them result in the deaths of animals that have been sent down to collect the tin from it; some of them result in a species of magical realism such as Novalis dreamt of, such that he sought to write an encyclopedia not simply after the image of the Diderotian disenchantment of superstitious nature, and not simply to respond by re-enchanting nature; but to provide a system capable of *everything*. So, what is the scope of universalism? Is it to establish *the* universal, such that everything else becomes a particular determination of it, in Spinozist manner, and to give universal names, or to give it a hinge such that the name might not be insufficiently determined by the actuality. Or is it in fact to continue to be part of the process of the whole self-manufacture? The universal manufactures itself – it is not manufactured by chemistry – I think that would ultimately be my answer to Bensaude-Vincent and Stengers.

C: There is a certain affinity between what we have described as the 'chemical paradigm' of thinking, and the legacy of 'universalism'. In the latter, thought begins with the mixture and the mixed rather than the elementary, from ratios of magnitudes (de Villa Nova, Bradwardine), from combinatorial configurations (Llull), from compositional potencies (Novalis) and from synthetic bundles of incommensurable fibres or ideas; thought must proceed from these mixtures in order to approximate or (re)produce the universal. We can go so far as to claim that chemistry is the first synoptic philosophy, in that its starting point is the full spectrum of nature as a universal mixture, or more precisely a unified continuum where the synthetic *topos* and the analytic *locus*, the universal and the regional, are mediated. So there must surely be an intrinsic relation between chemophilosophy and universalism. But is this relation simply a matter of observing how chemistry proceeds in the production of universals?

IHG: What immediately occurs to me about the universalism problematic – the problem of universals and particulars – vis-à-vis thought beginning with the synthetic, or indeed with the analytic, is something like the following: The universal, as contrasted with the particular, entails precisely the same kind of ontic restrictions that the particular does. In other words, if there is a universal, or indeed many universals, then it entails precisely the restrictedness of those universals to being particulars once again – particulars of a certain sort, i.e. ones that cover many. It's not clear that this would satisfy the demands of a properly synthetic or indeed synoptic philosophy.

I am interested, though, in the idea that chemistry is a synoptic philosophy that proceeds *from* the full spectrum of nature. It boils down to the following question: Does nature consists of particulars or not? And if it does consist of particulars, then, if thought begins with a mixture, then it's a mixture of particulars, ultimately, to which we would want to reduce it. If nature does *not* consist of particulars, on the other hand, then particulars are abstractions from, or processes of, the very nature that thought tends to synthesise, analyse, or synopticise with. And it strikes me that nature *cannot* therefore consist of particulars, precisely for the reason that chemistry is a synoptic philosophy – a philosophy that both synthesizes and self-analyses. In other words, if chemistry is properly a science of nature: if it offers itself as a model for thinking nature, a model for thinking nature that refuses an upper limit to synthesis or a lower limit to analysis, that begins *in medias res*, from the universal which is given as universal and of which the synoptic philosophy itself is an expression.

C: From the time of Lavoisier's chemical revolution onwards, we can see that there is an implicit connection between chemistry and political thought. Whilst the socio-political is recaptured and understood within the chemical continuum, the political chemistry underpins certain strains of philosophies of Nature which fundamentally determine the characteristics of modern European philosophy. How do you see the influence of chemistry on political thought and political chemistry on philosophies of nature since the inception of modern chemistry?

IHG: There's a really fascinating question about nomenclature – Lavoisier as being simply a 'nomenclaturist' of the elements. And the kinds of battles that were contemporaneous with that – Gay-Lussac, for instance, the anti-phlogistical crew and the phlogistical crew and so forth – they're all battling away, and one way that that's been regarded by historians of science is as a regional politics of scientific advance. Clearly it would be foolish to disregard that perspective entirely.

On the other hand, I want to know exactly how far we can take the analogy – or rather, how far we can take the *reality* – of a chemical politics, or a political chemistry. For example, it seems to me that if politics has a chemical basis, and let's say for example that it takes place independently of animals capable of political interactions, then and then only would it be possible for it to escape any kind of chemical base – but, assuming, therefore, that politics is of a chemical base, then what would it mean to talk about a political chemistry, other than a derivatively secondary parasitic account of the discovery of this or that element, or the domestic ownership of various chemical paradigms, of various means of doing chemistry? But that would surely entail a renewedly reciprocal relationship between chemistry and politics, such that the one determines the other, at the cost of the latter determining the prior. At which point, we have no direction; there is no relation anymore between politics and chemistry at all. That, I'd suggest, destroys both politics and chemistry, rather than, as it were, situating the political as an interestingly complex region, dare I say, of chemistry.

So there is that reciprocity problem, I have a worry about there being such a thing as the politics of chemistry that's approached in anything other than a metaphorical way. So the question I would want to ask in response, is: At what cost do we get a politics of chemistry? Are we talking about the politics of how chemistry happens to have been conducted in certain places at certain times? Because if so, then there clearly is a 'politics of chemistry'. But if we're talking about anything more substantial than that, such that it's determining the limits of the thinkable, or the limits of the actual, or the limits of what is, then we must be talking about a very bizarre form of politics that takes its cue from creation narratives of one sort or another ...

C: This is part of your general caution with regard to precipitate politicization.

IHG: Yes: under what conditions is it established that the conceptual is subject to ownership by its users? I'm aware that the cost of this is a species of Platonism, but I think the grounds for the refutation of Platonism have been grossly exaggerated!

C: Nevertheless: if political models of early chemical thought used to be the French Revolution and various affect-driven forms of socialism and class struggle, what would be the political model of contemporary chemistry in which chemical humiliation has been wedded to neuroscientific humiliation and planetary capitalism has its own chemical paradigm (from circulation, consumption and transformation of fuels and minerals to producing its own nature for the horizon of thought)?

IHG: One comes across this in Marx, where *Wechselwirkung* – 'metabolism' – is a constant trope. It's in the *Grundrisse*, it's in *Capital*, it's in the *Early Manuscripts*, and it's in the later scientific work. So the one thing that undercuts the althusserian rupture is precisely metabolism – which suggests one of two things: either Marx is an arch-romantic, in exactly the same way that Nietzsche is, thinking about *Bildung* in precisely the sense of the formative processes that take place in 'life', in living nature – and there are good grounds for making such a reading of Marx – or, that this really is a mere metaphor. And Marx himself is conflicted about it, insofar as he's a politician of *lebensrealismus*, believing that only certain types of entity can possibly be conceived of as being alive – 'Nature builds no machines', he says in the *Grundrisse*.[6] Equally there is no such thing as an automaton that moves itself – this is entirely a specious species created by the engines of capital for ideological purposes. And I'm simply not sure what it means to suggest that there is anything other than a *metaphor* of circulation that capitalism uses; just as there's a 'survival of the fittest' narrative that capitalism uses, and so forth. At which point, what is the additional question here? What is the real question at the basis of this – can there be a politics of nature such that the latter is derivative of the former?

---

[6] '[N]ature builds no machines' writes Marx in *Grundrisse* (trans. Martin Nicolaus [Harmondsworth: Penguin, 1973], 692).

C: From a socio-cultural angle, cooking is distinguished from nature's generative and synthetic processes, which span all cosmological processes. But from the point of view of nature, such a distinction is regional and myopic: Nature's self-cooking simply doesn't distinguish itself from culture or the culinary art. For Freud and Ferenczi, this relation between nature and culture is not merely limited to the synthetic field of cooking; it also holds true for eating and consumption. With that said, is it still possible to give a rigorous and systematic account of the culinary art without falling into the myopic realm of gastronomic fetishism? – Within the generative and universal nature, how can consumption and cooking, the gastronomic and the culinary, be distinguished from one another?

IHG: I'm intrigued by the point at which nature's 'self-cooking' arises, and the notion of fetish. For Freud as for Evans-Pritchard, for the late nineteenth-century anthropology of primitive societies, fetishism is precisely what results from an animist metaphysics. Things are alive, fundamentally, they're animated by spirit that moves them, and so forth. So it seems to me that the idea that nature cooks itself is already fallen prey, if not to a gastronomic, at least to a culinary fetishism. So the general question of fetishism is that it must be balanced against some species of panpsychism or panbiologism – maybe the antithesis of the fetish would be precisely the demonstrability of panspermia.

But there's a fascinating point here about the relationship between two sides of a problem: One situating gastronomy with respect to cosmology – or cosmogony, more importantly; and the other about extending the culinary all the way back to cosmogonic origins. There are two sets of problems there: one is that cosmogony would surely assert that the culinary, if it's the same as the origin of all things, defeats fetishism a priori in so far as it means that the entire universe simply is cooking itself; and the gastronomical is simply the differentiator between toxin and nutrition – a very long way down the chain, if you like. Or, if that's not an overextension of the culinary model – which it might well be, along the lines of my responses to the previous question – then on what grounds do we assert a 'self-cooking' of nature? It's a peculiar image, if you think about it – it's a schizogenic rather than a cosmogenic image. It's the self-production of cookery at the origin of time – which I agree can be thought, but at various well-known costs.

C: All that you have said about chemistry could be applied to your own philosophical work, which could be read entirely as a riposte to the notion that philosophers have a right to dismiss all questions of the history and contingent stratification or organisation of matter and thought – Kielmeyer's 'dynamics' – by way of ontologies (whether 'fundamental', mathematical, subtractive, or whatever) which *still* claim that there's nothing philosophically interesting about such 'accidents' or their metaphysical treatment. What's interesting about Quentin Meillassoux's point of view is that he takes this to new heights, claiming that even the laws of nature are accidental, non-necessary, not just their products. Let's attempt to crack open the Speculative Realist alliance in a new direction – what would be your counter-position here?

IHG: The short answer is that natural history is entirely, necessarily contingent; however, necessitation happens as a component of that.

C: Necessitation is contingent ...

IHG: ... Not the other way round: Necessitation takes place within contingent universes, and that would be necessarily true of any universe generated by any kind of process whatever.

C: Since for Meillassoux, contingency embraces not only the unreason of becoming and productivity but also indefinite states of frozen fixity, then maybe we should ask how chemistry could cope with these latter states, that are bereft of any processual dynamics? Is chemophilosophy able to think such an account of contingency?

IHG: So: If we accept that chemophilosophy is synthesis, and that synthesis has no upper or lower limits, then are there laws governing its development, and if so, are they universal with respect to that entire synthetic process? They would be, if and only if they were not themselves subject to synthesis, *which has no upper or lower limits* – which suggests that there cannot be laws that are co-extensive with the process – the laws must be emergent from it – that would be the difference.

C: Wouldn't that be consistent with Meillassoux's construction of hyperchaos: even randomness is a valid 'quotation' of hyperchaos – there is a hierarchical 'lamination' of laws and meta-laws at different levels (so that, for instance, randomness is regular and lawful at a meta-level). But hyperchaos is the intellectual intuition of the collapse of this whole stratal system – a 'pure chronics' – which makes possible to think a 'hard-edged' flipping from one state to another, from one regime of law or lawlessness to another, without reason. Is that 'intellectual intuition' of absolute contingency something unthinkable within a synthetic paradigm?

IHG: Does a chemophilosophy in fact rule out the sort of radical contingency that would have no determinable consequence? Is process, in other words, too rooted in nature to allow access to the kind of intellectual intuition that one can read from Meillassoux? I've rephrased the question in a loaded way, I guess: to say 'is it too rooted in nature' presupposes the nature of nature such that it would not be subject to the same sort of hyperchaotic possibilities of a sudden hard-edged change.

I don't see that there's any inconceivability to the idea that processes are suddenly emergent, immediately emergent, that there is spontaneity, and so forth, in the midst of natural process. There's an interesting parallel, actually, with a process that derives from Kant and the problematic of the transcendental account of causation. If you ask the question, what is the synthetic a priori, it's very easy to answer that in terms whereby the synthetic a priori becomes nothing more than an epistemology. But Kant's own account vitiates this: he says later on that the extendability of practical reason into the domain that theoretical reason cannot tread is one prospect for the transcendental, and therefore for the realization of synthetic a prioris, that is not simply epistemic, but practical. But then we have, at the conclusion of the Third Critique, this moment of terror in the face of the absence of finite rational beings from the surface of the earth; at which point it becomes clear that the stakes of the transcendental are *the re-engineering of causality such that time becomes a creature of finite rational beings*, rather than the other way around. And there's a clearly interesting consequence that flows from this with regard to the current question: If causality is subject to radical reorganization such that prior and posterior, ground and consequent, are entirely reorganisable, then what are we asking about when we ask about causality? Are we asking about anything that has any implicit a priori form that is subsequently realized – or does the re-constructibility of causality, the non-necessity considered in relation to causal form, does the number of possible causes, of thinkable causes, subject the very idea of causality to such indeterminism that the arrow of time is removed, at least potentially, that there being any cosmogenic process whatsoever becomes just one among many radical contingencies? Clearly it does; but crucially, this is on the back of an initial experiment which runs thus: is it possible that causality can be thought by finite rational beings in such a way as to make finite rational beings the causes rather than the consequence of causal processes? And it depends fundamentally, I would say, on an answer to that question, whether or not the species of radical contingency is *cosmologically* instantiable in the way that it might be intellectually intuited for, let's say, an *ontological* project. But if that's the case, if there is that difference, then what is the relationship between cosmology and ontology? And all of a sudden, we're back in the domain of metaphysics, which must have an account of the relation between ontology and nature, at some point.

So I think there's a similarity in the experiment about the re-engineering of time and cause ...
